If I have failed to make my meaning clear on any point, I shall be glad to do my best to explain it more fully. JOHN HARMER.

ART: ITS MISSION AND CATHOLICITY.

"Art is the expression of one soul talking to another, and is precious according to the greatness of the soul that utters it."—RUSKIN.

How little that hypothetical ape of the evolutionist realised the importance of his action when, in the murky depths of some primæval forest, he raised himself laboriously to an erect position, and shambled aimlessly along with his fore-legs hanging idly by his side! Those fore-legs! It is impossible to over-estimate the significance of their being left at liberty. Without them the Farnese Hercules would have remained unquarried and uncarved stone; Palmyra would never have cast the cool shadow of her stately buildings across the hot desert, and the complicated civilisation that exists around us at the present day would for ever have remained in its undeveloped state of primitive economy. Idle and useless those fore-legs may have been in the early days of our frugivorous ancestor's erectility, but the time came when necessity found them their application; and, of all events in the world's history, no one, from its ultimate result, seems to me so deeply interesting or significant as this one event of an ape's fore-legs, emancipated from their earth-service, finding an application. We can only be grateful to the necessity that occasioned their use, and speculate on what that use might have been. Perhaps, hard pressed by some fleeter enemy, he turned at bay, and hurled his missile of stick or stone with black hatred in his sloping skull, and art commenced with the flight of that missile and the mental force that directed it; for he was giving outward expression to the ideal of his mind—the annihilation of an enemy.

Those fore-legs, what have they not done since then? Through long ages have they been trying to express in an outward, visible manner the workings of their owner's mind; and the rude hieroglyphics chipped by the early Egyptian on the tomb of his dead was as much Art as the grand conception of Rubens that speaks to the world from behind the altar of Notre Dame at Antwerp, the question of their difference being, not one of kind, but of culture. We are too apt to narrow down to a few yards of canvas, a few tubes of colour, and the pet tenets of some particular school a principle that is the very foundation of human life—conscious expression with a specific object, or Art.

Thought may take many ways of making it self-ponderable, and the artist who thinks expresses himself in the medium best adapted to his nature; blind Milton and deaf Beethoven were artists giving outward expression to their lofty thoughts, the one in the printed page, and the other in the musical score. Any means of expression becomes Art, and the user of it an artist, whose *status* is determined by the importance of his conception and the legibility of its expression; for it is a great truth that, when some thinker confronts us with an urgent lesson or lofty ideal, be he artist in word or colour, we forget to be critical. Touch but our sympathies, and the dry husk of cherished canons falls from us, and, because of their eloquence, we forgive them their trespasses against some small rules we had framed for the cultured expression of their idea. Had Carlyle been a painter, he would have been a law to himself in painting as in letters: yet the man's mission to men would have spoken so dominantly in his pictures that we should have loved his irregularities and cherished them, as we now do his rugged use of the English language.

Two broad and, as it seems to me, sufficiently comprehensive divisions have been made in Art—the Useful and the Fine. To either one of these we can ascribe all human endeavour; for, as a careful thinker has well said, "All departments of life at the present day—Trade, Politics, Letters, Science, or Religion—seem to feel and to labour to express the identity of their law. They are rays of one sun; they translate each into a new language the sense of the other." But under the influence of civilisation the Useful merges imperceptibly into the Fine; or rather, Culture, seeing the coldness of bare Utility, seeks to overshadow its realism by the beauty of the Ideal. The woodland aisle or hewn catacomb was a sufficient home for the simple creed of the early Christian; but when, in the progress of time, that creed grew to be the ornate liturgy of the Romish and Greek Church, it was housed in the sumptuous Gothic minster. Hence do works of art become also a history of the Culture of mankind, "They denote the height of the human soul in that hour." The rude idol of the Indian, sheltered under its canopy of bark, bespeaks an imagination of the Deity less cultured than the elaborately carved and splendidly sheltered god of the Hindoo.

GEORGE T. HARRIS.

(To be concluded.)

Our Editorial Table.

BROMIDE ENLARGING AND CONTACT PRINTING, AND HOW TO DO IT.

By the Author of *Lantern Slides: How to Make Them.*

(London: The Fry Manufacturing Company, 5, Chandos-street, W.C.)

NOT the least attractive feature of this neatly printed little volume are the admirably clear and self-explanatory illustrations with which the text is interspersed. The Author betrays a complete grip of his subject in almost every line, and writes with such directness and lucidity that the instructions he desires to convey cannot fail to be comprehended by even the least experienced amateur. It is, indeed, as complete, intelligible, and succinct a guide to bromide enlarging as either the professional or the amateur photographer could desire. After discussing the advantages of the bromide process, and combating imaginary difficulties, the author deals with the choice of a paper, the factors influencing exposure, the kind of negative desirable, the apparatus, how to ascertain correct exposure, the fittings of an enlarging room, vignetting, printing in skies, enlarging by artificial light, development, dodging, toning, mounting, and finishing, &c. The pages on vignetting, printing-in skies, and mounting and finishing, are alone worth the small sum (6*d.*) which is charged for this very practical and comprehensive little manual.

FALLOWFIELD'S PHOTOGRAPHIC ANNUAL, 1892–3.

THE volume before us is, in all probability, the largest of its kind in existence. It occupies nearly 600 pages, and is illustrated by over 800 engravings. Truly, a mammoth catalogue! It would puzzle one to name any photographic article in current photographic demand that is not particularised in the *Annual*, which is a monument of commercial enterprise and industry. The hints and formulæ included therein are likely to be of considerable service to the amateur, and, take it altogether, the *Annual*, which as heretofore is well printed and got up, is a production of which Mr. Fallowfield may be proud.

PATENTS COMPLETED.

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS.

No. 14,648. ARTHUR RAYMENT, 99, Hatton-garden, London, and GEORGE LYONS, 19, Somerset-street, Portman-square, London.—*May* 28, 1892.

THIS invention relates to improvements in the ordinary photographic camera, which is made to fold up and lay closely together, so as to pack away easily, and only occupy a small space, such camera being usually mounted upon a tripod stand, as is well understood.

Our present improvements consist in so constructing, arranging, and mounting the "front," or part carrying the lens, that such front can be readily and entirely detached from the baseboard, so as to be easily folded up, and also can be readily attached in the desired position on the baseboard when setting up the camera for use, thus greatly expediting the operation.

For this purpose we arrange a hinge-pin or hinge-pins on the lower part of the detachable "front," and these pins (or pin) engage in eyelets or holes correspondingly formed to receive them in or on the baseboard.

This hinge-joint may be of any suitable character (and the parts, when thus hinged together, may be kept in the desired position by means of any suitable spring or springs or other equivalent appliance); for instance, the joint may be made after the manner of the well-known bayonet joint.

Furthermore, the front may be supported by an adjustable "strut," on one or both sides thereof, and the "front" being movable backwards or forwards (out of the vertical line if desired) upon its hinge-joint, can be firmly fixed in any desired position by the said adjusting struts, and the back being also adjustable as usual, our present improvements thus afford increased facility in operating with the camera as well as in speed in setting up and folding, and effects considerable economy of the space occupied by the folded camera, as by our present improvements we are thereby enabled to make such camera very compact.

A spring bolt, or spring bolts, may be arranged and mounted on the detachable front to engage with corresponding eyelets or slots in or on the baseboard (or *vice versâ*) formed to receive said bolts, such as in a similar manner to an ordinary door latch. Such bolts being thus self-engaging, and the slots, &c., to receive same, may be arranged in two or more separate positions, so as to readily set up the front at a greater or less distance from the focussing screen as desired.

AN IMPROVED MAGNESIUM LAMP.

No. 4999. EMIL WENIG, *Dresdenerstrasse*, 90, Berlin, Germany.—*June* 4, 1892.

This invention has reference to a construction of magnesium lamp whereby light or illuminating effects can be produced suitable for various purposes, such as taking photographs, for signalling purposes on ships or other places, and for theatrical purposes. The lamp can be used to produce lightning-like illumination or flashes or a constant light, the light obtained producing a more powerful effect than the electric light; and can advantageously be used for the purpose of giving signals, instead of other means heretofore used for this purpose, such for example as the foghorn, which is often deceptive as a signal. Magnesium, without admixture of explosive substances, is employed as the illuminating or flashing agent.

PROCESS FOR PRODUCING COLOURED PHOTOGRAPHS.

No. 6342. VICTOR MATHIEU, 9, Agincourt-road, West Hampstead, London.—*June* 4, 1892.

ACCORDING to this invention I produce, by the aid of the sunlight, or of strong artificial light, photographic negatives of such a character that prints made therefrom on sensitised paper, glass, gelatine film, thin skin, or other suitable material, shall be capable of receiving colouring in such manner as to resemble perfectly the objects photographed.

When working by the sunlight, in order to produce a suitable negative, I place in front of the object or in front of the sensitive plate a sheet of transparent glass of a blue, yellow, or red colour, according as the object contains much of blue, yellow, or red colour. These coloured glass screens have such an effect upon the coating of the negative that the print subsequently made therefrom can receive the corresponding tone or colour, or is rendered orthochromatic. I obtain in this manner a negative of a general grey tone, from which a paper print, when properly treated, will allow all the colours to pass or show through which belonged to the object photographed. The negative is developed and fixed in the usual manner by means of ferrous oxalate and hyposulphite of soda respectively. When working by strong artificial light, such, for instance, as the electric light, I project upon the object by means of coloured transparent glass, rays of blue, yellow, or red light corresponding as the object contains much of blue, yellow, or red. I develop and fix the negative in the usual manner, viz., by means of oxalate of potash, sulphate of iron, and bromide of ammonium, and by means of hyposulphite of soda respectively.

The paper or other material well albumenised is, for the purpose of my invention, quite immersed in a silver bath of about fifteen per cent. strength. The paper should be white and not toned, and should be an inch or two larger all round than the negative. After about five minutes' immersion I dry it in the dark, and then use it for printing from the negative. I put the print into a chloride of gold bath of usual character, and leave it in the bath until it assumes a black print or neutral tone. It is then fixed by hyposulphite of about ten per cent. strength, whereupon it is washed in water for several hours in the usual manner. The print is then put in a white blotter, and while still damp glued on to a wooden frame.

When quite dry by exposure to the air I coat it rapidly on the back with pure alcohol for the purpose of coagulating the albumen. When the alcohol has evaporated I coat it on the back with a liquid consisting of white Venetian turpentine mixed with pure alcohol, or with essence of turpentine, the proportion being by preference about half of each.

The print is then immediately placed in a suitable stove, by preference heated by means of methylated spirits or by gas, and which may suitably be of the form presently to be described. In this stove the print is heated to about 50° Cent. According to the difference in the quality of the sensitised paper, one, two, or three coats of the solution may be applied with stoving after each coating, but these stovings should be at a less heat than the first stoving—that is to say, at about 30° or 40° Cent. only. For very thin paper, one coating is generally sufficient. After about six to twelve hours' total stoving, the paper is dry and very limpid. The image is now more clearly visible on the back than on the front face of the paper, and it has acquired permanency because the stoving has reduced all the salts.

Before the colours are applied I give the back of the print a light varnish of isinglass, or, by preference, of a saturated solution of gum arabic with one-third of sugar candy added, to form an insulating surface, in order that the colours may not, by penetrating to the front, alter the transparency of the image. When this varnish has dried, I apply to the parts required on the back of the print by means of a brush, a palette knife, or a pad, the colours of the object photographed. The varying depths of tone in the print modify the effect of the colours seen through them. I only use oil colours or spirit colours. For retouching, if desired, I use colours and dyes dissolved in alcohol; these do not leave a trace of their presence on the image.

The print is now detached from its wooden frame, and may be mounted on Bristol board, on a suitable fabric, or upon a panel or board of some suitable material. It may then, if desired, be varnished with a good copal varnish, but I prefer that of Soehnée's manufacture. The stove may, as stated, be one heated by spirits or by gas, and of a square section.

When employing gelatine films I dry the various coats in a dry room without using stove heat, but my invention is not so useful for such films.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—1. The combined process for production of coloured photographs, consisting of the following successive operations, viz., the preparation of the negative for rendering it orthochromatic, the developing and fixing, the printing therefrom on paper or other material, previously prepared as described, the toning of the print in the chloride of gold bath in the manner described, the usual fixing and washing of the print, the coating or coatings with the solution for rendering the print transparent, the stoving or air drying operation or operations, the coating with the gum arabic solution or isinglass solution, and the colouring of the back, with or without the final retouching, substantially as set forth. 2. The application in the aforesaid process to the back of the transparent print of the gum arabic solution described.

IMPROVEMENTS IN CONNEXION WITH ARTIFICIAL LIGHT PHOTOGRAPHY.

No. 8145. CHARLES EARP ELLIOTT, 36, Jewin-street, Aldersgate-street, London.—*June* 4, 1892.

THE object of my invention for improvements in connexion with photography, taken by the aid of artificial light, is to provide a method and means for obviating or preventing the occurrence of deep, heavy, and decided shadows upon the picture, as obtains with the systems hitherto employed, and I attain this by the employment of a device or devices whereby the rays of light from the source employed are deflected and reflected, and generally diffused around and about the sitter or object to be photographed, so that only such shades or tints exist as tend to beautify the picture.

My invention consists of a portable tent or canopy, in one piece or in sections, and when placed together ready for use may be of any shape or size desired, but, preferably, rectangular, and not larger than is necessary for the purpose, the inside of which, or such part or parts thereof as may be desired, is, or are, lined or otherwise provided with a white or other light-tinted surface, adaptable, from a photographic point of view, as a surrounding for the sitter or object to be photographed. The artificial light employed may be any of those well known to the profession by which the most actinic effect can be produced, but I prefer to use that obtained by the combustion of magnesium ribbon, and a strip or strips of this is, or are, arranged or disposed within a suitable screen or shield, preferably semicircular in horizontal cross section, the flat side or base of said semicircle being the open or front part thereof, and coving said opening, and attached to such screen or shield by any convenient means, I provide an elongated surface having a central opening, through which the rays of light from the burning ribbon are reflected by the inner surface of the screen, this being painted or otherwise coated with a white, or other light-tinted surface, dull or glazed, as may be desired. Upon the said angulated surface when fixed upon the screen, I hinge or otherwise pivot, so as to cover the opening or aperture therein, and suitable number of louvres, but preferably four or thereabouts, each of which may be rendered adjustable to any angle by means of chains, supports, or quadrantal suspenders, or any other convenient means. The said surface and the louvres thereon may be painted distempered, or otherwise coated with a white or

other suitable flat tint, but preferably the former, and the apparatus so constructed may be mounted upon an adjustable tripod, or other stand capable of permitting the apparatus thereon to be raised, lowered, turned, or placed in any position desired, and the whole may then be suitably disposed within the aforesaid tent or canopy, at either side of the camera, and more or less facing the sitter or object to be photographed; and by a suitable arrangement of the apparatus and its accessories, to be hereinafter fully described, the light may thereby be deflected and reflected upon any part of the interior of the tent or canopy, or upon other reflectors or louvres suitably disposed therein, so that the light may by them be caused to expand, spread, or circulate, or be condensed, concentrated, or located, or otherwise diffused around and about the sitter or object in any desired manner for obtaining the best effect at the discretion or will of the operator.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

JUNE 28,—Technical Meeting, Mr. William Bedford in the chair.

THE SANDELL PLATES.

Mr. H. CHAPMAN JONES (the Hon. Secretary) said that he had written to Mr. J. T. Sandell (Messrs. R. W. Thomas & Co.) in connexion with the subject of the evening, and he had sent a number of prints, &c., in illustration of the properties of the new Sandell plates, with which it was claimed a great latitude in exposure could be had. Mr. Jones said he had himself made some sensitometer tests with the plates, which showed a far wider range of gradation than any others he had tested.

Mr. J. CADETT said there was no doubt that one could over-expose the Sandell plate much more in proportion than any ordinary plate, and still get a good printing negative. He did not think the prints sent showed the quality of the plate in any way at all. He knew the plates had the good qualities claimed, as he had tested them. With an ordinary plate very heavily coated they could get gradation far beyond the power of any ordinary printing paper. Messrs. Hurter & Driffield in their tests had found that an increased range was obtained with a heavily coated plate. With such a plate the limit was soon reached where the high lights could not be printed through. They were, in fact, limited by the paper. On a transparency they would get far better gradation. It was surprising the little range there was in an ordinary print—the negative was more perfect than the print. If he were going to considerably over-expose he should certainly use the Sandell plates.

The CHAIRMAN asked if there was any special advantage in having a slow emulsion underneath a rapid one?

Mr. CADETT thought the idea must be good—it was a good quality in a plate.

Mr. W. E. DEBENHAM said a good many experiments had been made years ago in mixing emulsions of different rapidities. How would that result as regards gradation?

Mr. J. D. ENGLAND said less gradation would be got in mixing emulsions.

Mr. CADETT also thought density would be apt to be lost. It was supposed that one would get a result the mean of the two, but the result favoured the slow emulsion.

Mr. ENGLAND thought much depended on the exposure.

REVERSAL, &C.

Mr. DEBENHAM observed that he had not been able to put off the point of reversal by any variation of development, and asked for the experience of others on the point.

Mr. E. CLIFTON had found that when the point of reversal was reached no modification of the developer, even though it were strained to the utmost, would prevent reversal of the image. Mr. Clifton subsequently observed that there was one point in Messrs. Hurter & Driffield's investigations which these gentlemen had not touched upon, and that was the mechanical obstruction offered by the gelatine itself.

The CHAIRMAN observed that Colonel Waterhouse's experiments had proved that reversal could be encouraged; could it also be retarded? Mr. Bolas might perhaps tell them something on the point.

Mr. T. BOLAS, F.C.S., in allusion to a former experiment of his with a bichromated gelatine film, said that the use of bichromate did not so much encourage reversal as tend to make it more definite than it otherwise would have been. If various developers could bring out reversal at various stages, reversal stepped in at varying points of development, and it could be either accelerated or retarded.

Mr. DEBENHAM'S point was that reversal could not be put off.

Mr. BOLAS asked whether a normal negative could be developed with Colonel Waterhouse's sulpho-urea solution?

Mr. CHAPMAN JONES said Colonel Waterhouse had tried and failed.

After further discussion, chiefly of a conversational nature, on the phenomena of reversal and halation, the meeting, adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 23, Mr. J. Weir Brown in the chair.

Mr. H. Barnes was elected a member.

QUESTIONS.

The following from the question-box was read: "What comparative exposure is necessary for photographing clouds as compared with an open landscape?"

Mr. E. HOWARD FARMER said one-fortieth to one-sixtieth of a second with *f*-8—that is about twice as quick.

The CHAIRMAN had given four seconds with *f*-16.

M. J. S. TEAPE had taken clouds with *f*-32 cap on and off. A very heavy cloud required as much exposure as a landscape.

Question: "Given two lenses, one of six inches focus used on a quarter-plate, and another of twenty inches focus used on a 15×12 plate, worked both at *f*-8—would the exposure have to be the same?"

Mr. P. EVERETT thought the ratios in both cases were somewhat different.

Mr. FARMER said that the shadows, or relief of the subjects, had a variation of from one to ten.

Mr. W. E. DEBENHAM said there would be less light in the corners of the pictures, but, as far as the subjects went, there would be no difference.

Mr. FARMER thought that the matter depended entirely on the subject. The exposure might be very different, or might be the same.

Question: "Has any one tried the effect of projecting a picture by means of a lantern on a background suitable for portraiture?"

After some discussion, it was suggested that Mr. Henderson should deal with the subject at a future meeting.

THE SURPRISE HAND CAMERA.

Mr. T. E. Freshwater exhibited and explained the "Surprise" hand camera, which carries six quarter-plate dry plates or films, automatically changed from the outside as rapidly as desired, and without any complication. The plates are held in wooden carriers forming the three vertical sides of a revolving triangular prism, the carrier being double, thus holding a plate on each side. A hand or arm revolves the prism upon its axis, and brings in turn each side parallel to the front of the camera. Before the triangle can revolve, it is essential to move a mask, which holds the plate in position, by means of a rod, underneath the camera, moved towards the lens over the pin, and, having revolved the prism, immediately replace the rod in its original position before exposing the plate. After the front plate has been exposed, the hand is turned round so as to bring to the front the plate No. 2, which was on the inner side of the carrier. The camera is in the hands of Messrs. J. Levi & Co., of Furnival-street.

PRIME FACTORS IN EXPOSING.

Mr. DEBENHAM resumed the adjourned discussion on Mr. Farmer's discourse, and said he thought Messrs. Hurter & Driffield's directions for estimating certain degrees of dulness of light did not go far enough. He had printed a negative in seven minutes which, two days later, was only half printed, although the light looked brighter. As to the value of colour, which Mr. Farmer told them varied as one to one hundred, he asked for an explanation. He could not see the reason for Mr. Farmer's advice to give an exposure in the studio four times more with a large head than with a small, the apertures being the same. Mr. Farmer had perhaps given the æsthetic rather than the photographic reason.

Mr. A. Cowan exhibited four negatives, each having the same exposure, but showing a gradnated difference in density produced by reducing the amount of pyro from two grains per ounce in the one case to one grain, half a grain, and a quarter of a grain respectively.

Mr. A. HADDON suggested the presence of moisture and wind as having influenced the disparity in Mr. Debenham's printing experiment.

After some further discussion, Mr. FARMER replied, and said that the object of his discourse had been to consider certain factors in exposing in addition to those given by the actinometers; there was no reason why they should not be taken into account. In estimating dulness as varying from one to four, Messrs. Hurter & Driffield took the altitude of the sun into consideration, but omitted London smoke or fog. The difference in the value of the reflections made an enormous difference in the exposure, a rule which applied to the case of large and small-sized heads.

North London Photographic Society.—JUNE 21, 1892, Mr. W. Coventon in the chair.—After the usual preliminaries, Mr. A. J. Spiller showed some fine prints by the new cold-bath platinotype process, taken from whole-plate negatives, Mr. B. J. Grover a series of hand-camera pictures taken in Cambridge on

Edwards' isochromatic films, and the President (Mr. J. Traill Taylor) showed a new stereoscopic shutter made for him for use at the Convention. The SECRETARY called special attention to the next meeting of the Society, to be held on July 5, when Mr. Howson, of the Britannia Works Company, Ilford, would introduce the subject of *Isochromatic Photography*. A copy of the Ilford *Manual of Photography* had been received for the Society's use, and samples of the Eastman Company's new chloride printing-out paper, received for trial, were distributed to the members. Mr. J. TRAILL TAYLOR then gave a conversational lecture on *Photographic Lenses, Ancient and Modern*, in which he compared the lenses in use by photographers prior to 1865, and about that period, with the lenses now in use, describing fully their principles and construction, and illustrating his remarks by diagrams and by the exhibition of a large number of lenses of all kinds, which were passed round for inspection. The lecture was highly appreciated, and a cordial vote of thanks was passed at its close.

North Middlesex Photographic Society, June 27th.—Mr. J. Stewart in the chair.—In the unavoidable absence, from illness, of Mr. Cherry, who was to address the Society, Mr. Marchant (the President) opened a discussion on celluloid films. After tracing the history of the material forming the support, he dealt with their advantages and disadvantages as compared with glass plates, and came to the conclusion that the balance was in favour of the films, a conclusion which was agreed to in the discussion that followed, in which Messrs. Stewart, Smith, Taylor, Cox, Staveley, Gregory, Barnard, and others took part. Mr. Cox then showed some silver prints of old date made by Mr. England which had retained all their pristine vigour, and also exhibited a curiously old-fashioned printing-frame dating from the 50's. Various other matters of interest having been brought forward, the usual competition of views taken at recent field-days was held, Chesham, Hanwell, and Wanstead being represented. In the last-named Mr. C. D. Gregory received the vote of merit. Three new members were elected. The first meeting in the next half-year will be held on July 11, when Mr. Gill will be in the chair, and a technical meeting will be held. Visitors welcome.

Holborn Camera Club.—June 24, Mr. Fred Brocas in the chair.—A number of slides by Mr. John A. Hodges were thrown upon the screen, including some excellent views of North Wales, Devonshire, Derbyshire, and some figure studies. These were followed by some members' slides of Mr. F. J. Cobb and Mr. N. Baker. A number of slides illustrating the *Detection of Crime* concluded the lantern show.

Hackney Photographic Society.—June 23, Dr. Gerard Smith in the chair.—Mr. HENSLER showed a yellow negative, and asked how to remove the stains. It was said that prevention was better than cure, and sulphite of soda was recommended in the developer. Mr. CAPEL asked how reduction took place on a light fogged plate. It was answered by saying that the silver was equally dissolved. It was recommended that a fogged plate reduced and intensified would give greater contrast. The CHAIRMAN recommended a weak solution. The excursion for Saturday was altered to Carshalton. Mr. Hudson showed cheap dark slides made by Chipper. Mr. GRANT said he had exposed a Sandell plate in the forest. It was dark, under trees, with patches of bright sky showing; used *f*-20, and gave twenty seconds about six o'clock, without getting any halation. The Assistant Secretary distributed samples of Eastman's gelatino-chloride paper. The report, given by Mr. HENSLER, of the Barnet plates (distributed at last meeting), was that they were very good. Mr. BARKER then opened a discussion on orthochromatic plates. The CHAIRMAN said if we looked through a purple glass at a view, we should see the immense amount of reds in nature. These, he said, orthochromatic plates brought out. An ordinary view, taken in average light, may be no better, but in a yellow light there was a marked advantage. Mr. DANDO said *The Million* used a dyed screen to obliterate all colours, but one which gave a relief to print from. Mr. GRANT had used orthochromatic plates for two years, and said in foliage there was a marked advantage over ordinary plates. It was announced that the next meeting would be on Tuesday, July 5, at 206, Mare-street, the Club's new quarters. Visitors are welcome to any meeting. Particulars of membership can be obtained of the Hon. Secretary, 12, King Edward-road, N.E.

South London Photographic Society.—June 20, Ordinary Meeting, the President (Mr. F. W. Edwards) in the chair.—Mr. F. W. Grigg was declared the winner of the award for the best print from a negative on Imperial plates. Mr. JAMES A. SINCLAIR then a paper on *Hand-camera Work*. The lecturer said the use of hand cameras was now becoming recognised, special classes being set aside for their work in recent exhibitions. He was in favour of a camera with a lens of about four and a half inches focus, working at *f*-8, but he usually worked with *f*-11 or *f*-16. The shutter should work in the diaphragm slot, opening and closing right across the lens centre, so that as much light as possible could be admitted during the time of exposure. The changing of plates should take place in the simplest manner possible—*i.e.*, automatically. For development he advocated the use of pyro, getting as much detail as possible, and then strengthening the negative if necessary. Mr. Sinclair's remarks were criticised by several of the members present, and some divergence of opinion was expressed. It was an attendance of forty. Messrs. R. & J. Beck exhibited and explained their "Frena" hand camera, together with some enlargements from negatives made with it. Messrs. Houghton did the same with their "Shuttle" hand camera, showing specimens of work produced by it.

Brixton and Clapham Camera Club.—June 21.—Mr. W. H. Smith, of the Platinotype Company, demonstrated the working of their new cold-bath paper, pointing out the directions in which it was superior to the papers previously made. One advantage it possessed in being amenable to special treatment in cases where local development was desirable. This consisted in the application of glycerine to the printed proof either with a brush or sponge, or even by boldly rubbing it on with the hand. This had the effect of retarding development to some extent, and allowed the development of the print with the brush and oxalate solutions of various strengths. This method was specially applicable to cases where solarisation in the dark parts was to be feared, or where it was desired to render certain parts in a lighter tone than they would appear in an ordinary print. The granularity which would probably make its appearance under these circumstances, were the hot-bath paper used, was conspicuous by its absence, and, what was certainly contrary to expectation, the finished print did not betray by patchiness or harsh outlines that any special treatment had been given. On Saturday, the 25th, the annual excursion to Bexley, by invitation of Mr. Dresser, took place. Ample opportunities for picture-making presented themselves on the farm and by the River Cray. After tea Mr. J. W. Coade, Vice-President, on behalf of the members, asked Mr. Dresser's acceptance of an illuminated address, expressing their thanks for his services as President during the last three years.

Leeds Photographic Society.—The first excursion of the Society should have taken place on the 18th instant, but the weather was so bad that, after sheltering for about an hour, a retreat was made for home. Fortnightly meeting, June 20, Dr. Jacob (President) in the chair.—A set of prize slides were to have been exhibited, but did not arrive. This is the second time this season that this Society has met to see these slides, and been disappointed, and on each occasion the excuse has been the carelessness of a clerk in not booking the engagement. The members scarcely seem able to stand a third disappointment, so it was decided not to trouble the owners of the slides to make another engagement.

Midland Camera Club.—June 24, the President (Dr. Hall Edwards) in the chair.—This was the second of the Elementary Evenings, and there was a fair attendance. The subject was that of Development, and the President gave a very interesting demonstration, using a number of different developers upon negatives he had taken the previous day. Several new members were elected and proposed. By the kindness of the Eastman Company, a sample packet of their gelatino-chloride printing paper was presented to each member present. Much interest was shown in the Club's first outing, which is to take place on the 10th of this month.

Photographic Society of Japan.—May 13, Annual Meeting.—There was an exhibition of work by members and of apparatus during the daytime. Amongst other things were shown a large collection of the most modern apparatus by Mr. R. Konishi; a set of photographs on porcelain, excellently reproduced; a series of fine prints on gelatino-citro-chloride paper, by Mr. G. Brinkworth; and an album of the Tokaido, by Mr. K. Ogawa. The SECRETARIES read their report for the past year, which showed the Society to be in a prosperous condition. Mr. K. OGURA read a paper on *Stripping Gelatine Films*, and gave a demonstration of the process. Afterwards Mr. T. SAITO demonstrated the *Stripping of Collodion Films, and the Applying of them to Wood for the Engraver*. Both demonstrations were highly successful. Mr. C. D. WEST then read a short paper on *A New Toning Process for Silver Prints*. This process is simplicity itself. The prints must be on plain paper. They are printed in the usual way, are fixed, and are then thoroughly washed. After this they are dipped in a solution of sulphuretted hydrogen till they reach the tone wished for. Prints were shown that were of an excellent tone. Mr. WEST said that probably photographers would think that such prints were of necessity the reverse of permanent, but he saw no reason to think so. Sulphide of silver was really the most permanent silver salt he knew of. As a matter of fact, he had failed to make any alteration on prints either by dampness or by the action of light during one year. After this paper was read Mr. W. K. Burton exhibited the action of a very novel form of optical lantern that had been brought from America by Dr. A. H. de Guerville. This apparatus, although occupying little more room than an ordinary limelight lantern, distils its own oxygen and hydrogen substitute as the exhibition goes on. Considering that the gear was in the hands of a lanternist of but slight experience, and that it was tried by him only for the fourth time, it worked with remarkable smoothness. The light was of extreme brilliancy, and the audience seemed to highly appreciate a set of scenes that were projected on the screen.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

"TALBOT ARCHER" AND THE CONVENTION.

To the EDITOR.

SIR,—Your contributor, "Cosmos," makes some grave allegations against Mr. W. Jerome Harrison without advancing a tittle of proof to support them. This is not fair and not just, although, to judge by his recent remarks in your pages on other subjects, such conduct is quite characteristic of "Cosmos." This gentleman may be as ancient and lofty an authority in photographic matters as he sets up to be, but I don't think that he is at all entitled on that account to make such serious charges without at the same time furnishing better proof than mere hearsay.

I know Mr. W. J. Harrison so well as to be certain that he would not seek the cloak of anonymity to hurl untruthful and spiteful charges against the members of the Convention, either individually or collectively, and therefore I am confident he is not "Talbot Archer." Besides, does "Cosmos" think that a man of Mr. Harrison's position could possibly descend to the practice of praising himself in *Anthony's Bulletin*, which is what Mr. Harrison would be guilty of doing if "Cosmos'" allegation were true? I read *Anthony* regularly, and I have long observed that Mr. Harrison's name figures frequently in "Talbot Archer's" English notes. But why is this? Because Mr. Harrison is such a prominent figure in the English world of photography, and is always to the fore in the army of progress. Consequently, "Talbot Archer," as an accurate chronicler of English photographic history, could not, or at least should not, ignore the large part which Mr. Harrison fills therein.

I hope that concurrently with this letter you will publish an indignant denial from Mr. Harrison, and that "Cosmos" will be forced to apologise for traducing him.—I am, yours, &c., BRUM.

June 27, 1892.

HELIOCHROMY.

To the EDITOR.

SIR,—I regret that I am obliged to occupy your valuable space with replies to statements which ought never to have been made.

Dr. Vogel (p. 382) appears to accuse the members of the Committee on Science and the Arts of the Franklin Institute of having acted in ignorance of facts which Dr. Vogel himself knew that I had communicated to them some time before they issued the report indorsing my claims. In the identical statement that was submitted to Dr. Vogel for criticism, I gave due credit to that gentleman for his use of corallin in 1873, and to Becquerel and Du Hauron for their experiments with chlorophyl. Dr. Vogel also certainly knows that Du Hauron never gave up my chlorophyl process in favour of Dr. Vogel's eosine process. Du Hauron never made use of either of the processes referred to, but used chlorophyl according to a method of his own, and eosine according to the method of Colonel Waterhouse.

Dr. Vogel's reminder that he published his alleged "new principle" in 1885 is not pertinent, because my process is quite different in principle and in practice from anything that is possible in accordance with it. I am quite certain that Dr. Vogel's idea cannot be carried out in accordance with the facts which support the Young-Helmholtz theory of colour vision. As a principle of colour selection in the negative-making process, it is utterly indefinite, and as a guide for selecting the printing colours, it is positively wrong as applied to the triple print process.

In reply to my intimation that he quoted the only unfavourable expression of opinion of my process that he had been able to find in print, Dr. Vogel now quotes from *Photography* a remark that had no reference to either process or results. The Editor of *Photography* said he was "somewhat disappointed at the attendance" (at my first lecture), but that "the beauty of the results which were shown, however, was great." Will Dr. Vogel make another search?

Dr. Vogel is also in error when he says that he "acknowledged" the heliochromoscope on page 318. My statement that he had ignored it altogether was strictly true.

Mr. Scott's letter is mostly a repetition of assertions which are sufficiently answered in my former letters. He had not patented anything new except a particular form of single-light lantern for multiple image projection. My system of 1888 gave perfect register, which is impossible with images made in the way Mr. Scott advocated. Pictures of quite near objects in relief will not register sufficiently well if made from points of view even as much as half an inch apart. The subjects which I have been showing in the heliochromoscope would have been complete failures if made in that way. Mr. Scott must use my camera as well as my processes if he would succeed. FRED. E. IVES.

London, June 17, 1892.

ORTHOCHROMATIC PHOTOGRAPHY.

To the EDITOR.

SIR,—Dr. Vogel wishes to make a few corrections with regard to some statements made at the meeting of the Photographic Society of Great Britain, and asks me to send the following reply for publication:—

"DEAR SIR,—You are reported to have said, at the meeting of the Photographic Society of Great Britain of the 15th inst., that I was one of the first to experiment with orthochromatising bromide of silver. Allow me to correct your statement in so far that I was *the first* who made such experiments, and that my results were at first not understood, and remained unconfirmed by other experimentalists in the same subject. My discovery was made in 1873, and it was not until July, 1874, that Becquerel, of Paris, and 1876, when Colonel Waterhouse proved the correctness of my statements, that the matter met with general acceptance from the leading experimentalists of the time.

"With regard to the statement by Captain Abney, that I had said I could not get an orthochromatic plate with an excess of bromide, the statement (made in 1876) had reference to *collodion plates*, and not to gelatine. The statement seems, therefore, to rest on a misunderstanding.

"Mr. Spiller's opinion, that an eoside of silver could be formed when eosine is added to the plain emulsion, is contradicted by most authorities in such matters, foremost by Dr. Eder, who holds that eoside of silver can only be formed when eosine comes in contact with a soluble salt of silver, such as silver nitrate. An excess of bromide of silver is, however, present in every emulsion, which will immediately destroy the eoside of silver by forming bromide of silver. The assumption, therefore, that bromide of silver, on being dissolved by the ammonia present, will form coside of silver, is inadmissible, for the silver has the greater affinity for the bromide than for the potassium, which would have to be formed first; also the other assumption, that nitrate of silver would destroy the erythrosine (tetraiodide-fluorescein) by combination of the iodine with silver, is not correct. I have erythrosine-silver plates one year old in which the unchanged erythrosine is easily recognised by the spectroscope.—I am, dear sir, yours truly, (Signed) Dr. H. W. VOGEL.

"*Berlin, June* 25, 1892.

"Mr. J. R. Gotz, London."

I have nothing to add, but that I am not able to repeat the exact words I used at the meeting, but that it appears to me that I could hardly have used them as reported. That Dr. Vogel first discovered the property of different dyes as local sensitisers is an undisputed fact, which needs no further assertion.—I am, yours, &c., J. R. GOTZ.

19, *Buckingham-street, Strand, W.C., June* 27, 1892.

To the EDITOR.

SIR,—I am awaiting some further information, and shall, next week, be enabled to answer Mr. Edwards' letter very fully.—I am, yours, &c.,

June 28, 1892. J. J. ACWORTH, PH.D.

THE DARK FLASH.

To the EDITOR.

SIR,—During the storm of Tuesday last, I observed an effect that would undoubtedly have produced the much-discussed "dark" flash if reproduced on the photographic plate. It was simply that the colour of the flash was a dull red, relieved against a background of the usual kind when clouds are illuminated with an electric discharge. Probably others may have noticed the same effect and drawn the same inference.—I am, yours, &c. E. DUNMORE.

27 *Glenthorne-road, W., June* 29, 1892.

THE NEW PLATINOTYPE PAPER.

To the EDITOR.

SIR,—I have started working the new platinotype paper, but the results are not promising. The prints appear mottled, although I have followed the instructions most carefully, and have also tried different exposures from the same negative with a like result. The paper was supplied by an agent. Do you think that the paper is to blame, or can you give me any cure for the evil? If you can do so I should be very thankful. I may also state that the pictures are stored, also paper, in a proper calcium tube.—I am, yours, &c., A. C.

June 27, 1892.

[We have had no experience of the failure with the new platinotype paper such as our correspondent indicates, and, therefore, are unable to suggest a remedy. Perhaps the Company would be disposed to come to his assistance, and allow photographers generally to receive the benefit of their advice.—ED.]

EMIGRATION TO THE UNITED STATES.

To the EDITOR.

SIR,—I will be glad if you will inform me what you consider the relative prospects of workers in this country and in the States. I have had some experience in dry-plate factories on this side, and am acquainted with most of the ordinary details of emulsion-making. Do you consider I would get the best chance of doing work by stopping here or by emigrating?—I am, yours, &c., JOHN PARRY.

June 25, 1892.

[Questions such as that conveyed in our correspondent's letter are constantly reaching us. For his information and that of many others we may here state that America by no means offers a better field for photographic enterprise of any kind than this country. We should, therefore, be chary of recommending emigration in any but exceptional cases.—ED.]

SPEED OF PLATES.

To the EDITOR.

SIR,—Mr. Phillips' letter of June 17 is evidently written in a genuine spirit of investigation, and what I have to say in reply is not of necessity antagonistic to his views, nor does it follow that I am adversely interested in criticising Messrs. Hurter & Driffield's method of measuring the sensitiveness of plates. No method will have the slightest chance of being generally adopted by plate makers until it has been adopted as the standard method by a representative committee of the leading society or societies, and when this is done, all makers of exposure instruments and tables will adopt the new standard alike.

Mr. Phillips covers rather a wider field than I did in my letter of May 20, and I shall try to keep within the subject. I entirely agree with his explanation about "subject numbers." As I mentioned in demonstrating my instrument before the Camera Club, "correct exposure" is a mere phrase when applied to a group of objects of various colours, and really means the best *compromise* which can be made between the right exposure for the white or grey objects and the right exposure for the most non-

actinic ones. This compromise is represented by the subject number, 100 in my exposure system, and, as Mr. Phillips remarks, it is fairly representative of most groups of objects usually photographed.

It is because this typical standard object is very far from being white or grey that I object to any scale of *white*-light sensitometers being adopted as a standard. With regard to Mr. Phillips' remark about the "restricted observations" made with a Spurge's sensitometer, and the need to study the behaviour of a plate to many varying amounts of illumination, I must point out that when a plate is exposed to light in a Spurge's sensitometer it is exposed to twenty-four varying amounts of illumination, with just as much accuracy and far more convenience than if it were exposed to a standard light in varying portions for one, two, four, eight, &c., seconds.

If I were to expose two plates of different rapidities in the instrument, and found that in the one case the light which had passed through a diaphragm of *f*·22 had produced the same opacity on the plate as that which had passed through *f*·32 in the other case, I should know that half the amount of light is required to produce this given opacity in the case of the second plate than in the first; or that half the duration of the same light would do the same thing, and I should conclude that the second plate was twice as sensitive to white light as the first.

I do not say that Messrs. Hurter & Driffield's method of "finding the first term of a series of illuminations ever doubling, in which the densities of deposit increase, approximately, by equal differences," is not an accurate method of ascertaining the white-light sensitiveness of any plate, but I strongly protest against its being stated as the only correct method of attaining the same end. I shall defer giving my exact views on this subject until I can give them in a more complete form, as a contribution to the coming problem of a standard sensitometer, which shall give correctly the camera sensitiveness of plates.

I had already adopted Mr. Phillips' suggestion about comparing the speed numbers of the actinograph with the plate numbers for my exposure meter, and in the sixth edition of instructions for my instrument, the following footnote is appended to the list of plate speeds:—"Marion's plates are now marked with a speed number (actinograph), which, multiplied by one and a half, gives the P. number. Thus, Act. 40 = P. 60."

In reply to Mr. Phillips' final query, the photometer I use is the simple one described by Captain Abney, in the latest edition of *Instruction in Photography*. An opacity of eight, lets through one-eighth of the light; an opacity of one hundred, has a transparency of one-hundredth, and so on. As this instrument is quite different from Captain Abney's Sector Photometer, I am unable to give any information as to the value of the figures in the latter instrument, or to say which instrument Captain Abney has used for his published observations.—I am, yours, &c.,

ALFRED WATKINS.

Hereford, June 25, 1892.

THE EASTMAN GELATINO-CHLORIDE PAPER.

To the EDITOR.

SIR,—I see in your issue of to-day that you confirm the good opinion I had formed of the new Eastman gelatino-chloride paper. I wished to have your opinion in using the combined bath. Is there any danger in using it in any way?

I notice the Ilford people condemn it roundly; but it is inconceivable that the Eastman Company should recommend it if there was the slightest danger.

I want to use it, as it saves a bath and a washing.—I am, yours, &c.,

June 24, 1892. G. R. C.

[According to our experience, which of course is brief, there is no danger in using the Eastman Company's combined bath.—ED.]

MARBLE-LIKE STAINS.

To the EDITOR.

SIR,—I notice in report of the People's Palace Photographic Society in last week's JOURNAL, that Mr. G. Kendal, referring to his previous experience of marble-like stains on his plates after developing, said that he had overcome that by putting the plate in water before flowing on the developer. He was, however, still unable to account for it. I might say that I invariably soak my plates before developing, and yet sometimes these stains appear. After investigating (soaking plate and also pouring developer on dry plate), I find the stains are due to insufficient washing, *i.e.*, after leaving the developer, and before putting into the fixing bath.—I am, yours, &c.,

HENRY V. LAWES.

June 27, 1892.

CORRECT EXPOSURE.

To the EDITOR.

SIR,—In photography, as in many other matters, an ounce of practice is worth a ton of theory, and therefore I give due weight to Mr. Watkins' experiments for the purpose of clearing up this matter; and, if my experience agreed with his, would at once admit that there must be some factor left out of account in the theoretical statement of the case which, if taken into account, would reconcile both theory and practice. Mr. Watkins wonders if I have made any definite trials with a view to finding out the truth of this matter, and, to be candid, I must admit that I have not; but, in every plate I expose, I take into account the amount of subject included by the lens on the plate, and so, in a sense, am constantly making a definite trial of the theory, and sometimes I have more nearly realised the exact conditions of Mr. Watkins' experiment, for I have taken two photographs from the same standpoint, with lenses of different focal length, and have varied the exposure so as to give less where the lens of shorter focus is condensing on the plate the larger amount of light transmitted by the larger amount of reflecting surface.

Mr. Watkins excuses himself from "entering into an explanation of the fact *why* a large amount of subject reflects no more light to a square inch of the sensitive plate than a small amount does" apparently on the ground that "it is a question which the opticians have not touched upon." Perhaps, Sir, you, as an authority on optics if not an optician, may think the subject of sufficient value to devote a few lines of explanation to the elucidation of the matter.

With regard to Mr. John Sterry's letter on this subject in your issue of June the 24th, in attempting to show that I have omitted to make allowance for the different area of stops used, he himself omits to take into account the elementary law of optics, that the intensity of the illumination of an object varies inversely with the square of the distance from the source of light; in other words, he forgets that with two lenses of different foci the plate is at a different distance from the stop which regulates the amount of light admitted to the plate, and it ought to be needless to point out that this is one of the factors necessary to be taken into account in regulating the size of lens stops, and in the statement that two lenses are working at the same intensity.

Mr. Sterry's statement should, therefore, run: "In the second case, four times the area of object, giving four times the light, is made to cover the same area of plate as in the first instance; but the stop has been reduced to a quarter of the area, and allows exactly the same amount of light to pass as before." The plate, however, has been brought to half its former distance from the stop, and therefore is four times as brilliantly illuminated as in the first case.—I am, yours, &c.,

June 25, 1892. M. J. MICHAEL.

Exchange Column.

*** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange 4s Dallmeyer's patent portrait lens for 2s or 3s ditto and cash.—Address, A. E. & C. FOX, Bradford.

Exchange ship's chronometer in good order for 15×13 modern camera, long extension, with lens.—Address E. F., 156, Loveridge-road, N.W.

Will exchange some canvas scenic backgrounds for imitation rocks and rustic accessories. Cabinet photographs of each background can be sent.—Address, W. HOBBS, The Studio, Saffron Walden.

Will exchange new burnisher, by Vevers, twelve-inch oscillating bar, for good posing chair, with two or more backs, or plush or velvet studio curtain, or offers.—Address, HORTON, Photographer, Caroline-street, Cardiff.

Would exchange THE BRITISH JOURNAL OF PHOTOGRAPHY, 1890 (part bound) and 1891, for half-plate and quarter-plate deal box (12 grooves each) with lock and key, or scales and weights.—Address, SANDERSON, 16, Shaftesbury-avenue, Lower Weston, Bath.

Pearson & Denham's quarter-plate detective camera, six double backs, two finders, tripod, Shew's patent rectilinear and shutter, cost seven guineas; exchange light whole-plate or half-plate camera, or Hughes' Pamphengos.—Address H. A. COUCH, 11, Waterloo-crescent, Dover.

Will exchange half-plate rapid rectilinear lens, Ross No. 2 portrait; 12×10 camera with two double backs; interior and exterior backgrounds wanted, head and body rest; studio camera stand; studio chair with four backs.—Address, H. WAKEFORD, 21, Station-street, Sittingbourne.

Wanted, portrait lens (cabinet), in exchange for fourteen volumes of *Amateur Photographer*, from October 10, 1884, to October 6, 1891, also several shilling publications. Two numbers out of the fourteen volumes missing.—Address, F. ASHELL, 16, Grove-terrace, High-road, Tottenham, N.

Will exchange background of verandah (will answer as exterior and interior), size 8×7 feet, for exterior background, also grand carved table (solid wood, good size), for a rustic accessory suitable for different positions. Photographs exchanged.—Address, W. MORGAN, Graus Pwllheli, North Wales.

Exchange for 12×10 modern outdoor camera, with double slides, or four back chair, seven years' BRITISH JOURNAL OF PHOTOGRAPHY, Seavey's rustic bridge, backgrounds interior and exterior, Ross's wide-angle doublet, 10×8, ditto, whole plate.—Address, W. B., Prospect Villa, Stoke-road, Guildford.

Wanted, backgrounds; will exchange BRITISH JOURNAL OF PHOTOGRAPHY from January, 1890, to December, 1891, and twenty-seven odd numbers. Also *Practical Photographer* from January, 1890, to December, 1891. Also good oil stove, by Rippingille, cost 2l.—Address, H. WELFORD, Graham-street, Penrith.

Answers to Correspondents.

**** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

BELL.—Apply to Mr. W. E. Debenham, 46, Haverstock-hill, N.W.

C. P. W.—1. Probably not. 2. Yes, but starch is generally preferred.

FOG.—There is an article on utilising fogged plates in the JOURNAL for July 3, 1891.

W. J. STILLMAN.—Received. Negatives not to hand at the moment of going to press.

J. C.—Both cameras are excellent for the purpose; the lens named would do for No. 1.

J. PATTERSON (Cavan).—You omitted to forward the concluding portion of your letter.

G. JOHN.—In the volume of the JOURNAL for 1890 you will find a series of papers by Mr. Lyonel Clark on the subject.

CYMRO.—The scratches would in all probability not interfere with the working propertics of the lens. But why not put the point to a practical test?

H. COUCH.—The method is a trade secret, but in all probability preparation of the celluloid surfaces is not essential. Coat them as far as is possible in the same manner as glass plates.

CARMENZ.—1. No. 2. Under-exposure. 3. The developer does not seem to be at fault—that is, with an excess of alkali. Probably you employ the solutions at two high a temperature.

BOGUS.—If the pictures are registered, you have a legal remedy against the man; but, of course, he is not bound to tell you where or how he obtained them, unless the question is addressed to him in a court of law.

GREEN says: "I shall feel much obliged if you can tell me the proportions of ether and spirit to use for thinning transfer collodion as used for developing carbon prints on glass."—Usually, this collodion is made with equal parts of ether and spirit as solvents. But, as in use the ether evaporates faster than the alcohol, the collodion should be thinned with two parts of ether to one of the alcohol.

K. L. (Fallgarh, N.W.P., India) says: "Would you please let me know which of the so many processes for reproduction that are in vogue is the easiest, cheapest, but yet artistic, and which can be worked here without any difficulty? I require about one thousand copies every second or third month of drawings, portraits, &c., which I desire to reproduce myself. I have a fair knowledge of drawing, painting, and photography."—The collotype process would undoubtedly be the most suitable.

MISS H. E. says: "Will you let me know what is considered a fair weekly salary for lady retoucher and book-keeper, several years' experience, hours 9.30 a.m. to 7.30 p.m., living out, an hour allowed for each meal (dinner and tea), work considered by employer good, and averaging about half a day's retouching and half a day's book-keeping, including sending out of all accounts quarterly, some reception-room duties and superintendence of photograph orders and some correspondence?"—We should think a weekly salary of thirty shillings would be a fair remuneration.

CARDIFF says: "Having taken a half-plate portrait of a near friend of mine that is now in India, I have unfortunately destroyed the left eye by letting it get damp; otherwise everything is very good, and, as it will probably be years before we meet again, I would ask you to kindly inform me by what means it will be best to rectify my misfortune—whether to spot the negative or to treat the silver print, also whether to use water-colour paint or pencil?"—It is impossible, without seeing the negative, or a print from it, to judge of the kind of damage, to say the best way of dealing with it. If our correspondent can touch out the defects in the negative, that will be the best procedure, and it matters not whether pencil or water-colour is used, so long as the desired result is obtained. If the injury cannot be remedied in the negative, a print taken before the damage was sustained should be copied, and the new negative utilised.

A. M. M. asks: "1. Where can detailed information be obtained as to the use of a mirror for photographing clouds so as to utilise the polarisation of light? 2. Under what circumstances is the method most effective? 3. What should be the position of the mirror? 4. What kind of mirror should it be? 5. Where can detailed information be obtained as to the use of Nicol's prism for cloud effects? 6. How do the following methods compare as regards cloud effects: (*a*) Ordinary dry plates; (*b*) orthochromatic dry plates, with or without screens; (*c*) mirror method; (*d*) Nichol's prism method?"—Instead of replying *seriatim* to these queries, we shall lump them together in the following remarks:—In this JOURNAL for January 30, 1891, and on page 72, an excellent and practical paper *On the Use of Black Glass Mirrors for Cloud Photography*, by Mr. A. W. Clayden, will be found. In this paper the first four queries are clearly answered. We remember many years ago writing an article on the application of the Nicol prism for this purpose, but are at present unable to give the date of the JOURNAL in which it appeared. When conducting the experiments which led to the publication of the article in question, although our prism was what is usually considered one of large dimensions, yet did we find a serious drawback to arise from the narrowness of the field included, and waited for the advent of one which was said to be at that time in course of construction by Ahrens, and by which a large angle would be included. Circumstances arose which prevented this line of research being prosecuted. In the wet collodion days black glass plates (in reality a very dark purple) were articles of commerce for collodion positives, and some of these were very flat, and polarised the light well. We are unaware whether any of these are now procurable. All our cloud experiments were made with wet collodion, hence we are unable to reply to the sixth query. If this falls under Mr. Clayden's eye, he will probably kindly supplement what we have said.

THOS. BRAMWELL.—With very thin negatives—those wanting in contrast—it is difficult to obtain vigorous prints on albumen paper. Such negatives are also unsuited for platinum printing. Negatives of this class may, however, be utilised with advantage for printing on bromide paper. Strong negatives are not necessary for bromide printing.

PRINTER writes:—"Last summer I wrote you asking for a cure for blisters in silver prints, to which you kindly advised the use of methylated spirit, which I used last year with every success. This season the spirit seems a terrible enemy—the prints I have done with it go quite yellow in about a week; would that be caused by the naphtha in the spirit? I notice in the washing waters after soaking prints in the spirit, that there is a lot of stuff that looks like paraffin, but what it really is I cannot say. My prints have twenty minutes in hypo, they then have about fifty changes of water, are left in running water all night, and have fifty changes in the morning. I use ——'s *non*-blistering paper, or at least, so they guarantee it, but I find it blister up about the size of five-shilling pieces, unless the spirit is used. If you can advise me in the matter I should be greatly obliged. Is there any substitute for the spirit?"—The example sent has all the appearance of an imperfectly fixed print, though that should not be the case with twenty minutes, immersion, supposing the solution is of the usual strength and the hypo of good quality. We can scarcely imagine, without definitely putting the thing to the test that the addition of the petroleum sprit to the alcohol can influence the fixation of the prints.

(*Several other correspondents in our next.*)

BRIXTON AND CLAPHAM CAMERA CLUB.—July 19, *Photographic Apparatus and its Use*, by the Hon. Secretary.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—July 2, Outing to Theydon Bois; Leader, Mr. Pask. 7, *Intensification*. 14, Members Open Night.

MR. JOSEPH PURNELL, Photographic Printer, of New Malden, died on June 23, aged sixty-five years. He was one of the very early photographers, having entered the profession about 1855.

PHOTOGRAPHIC CLUB.—July 6, *The Solubility of Photographic Chemicals* 13. *Photographing Natural History Specimens*. Outing, Saturday next, Stanmore. Train from Euston, fifteen minutes past two; Broad-street, forty minutes past one.

MUTUAL IMPROVEMENT POSTAL PHOTOGRAPHIC SOCIETY.—As there are several vacancies in the above Society, amateurs willing to join are requested to send their names and addresses to the Hon. Secretary, Albert B. Moss, 64, Wood-lane, London, W.

WE are deeply sorry to learn that on Wednesday evening last, on the occasion of the fatal balloon accident at the Crystal Palace, Mr. C. V. Shadbolt (the well-known aeronantic photographer, and son of Mr. George Shadbolt, a former editor of this JOURNAL), who had also made the ascent, met with very serious injuries. At the time of writing the unfortunate gentleman is in a very precarious condition.

As it may be agreeable to members of the Convention going to Edinburgh by sea to travel in company, we have made inquiries as to the best steamer sailing from London on July 9. The *Seamew*, of the General Steam Navigation Company's fleet, which is said to be the largest and fastest steamer on the station, is appointed to sail on that day. A tender leaves Westminster Bridge at noon, calling for passengers and their luggage at the Temple Pier, and Old Swan Pier. Passengers wishing to join the ship direct should be at Irongate Wharf at noon. Those who prefer travelling to Edinburgh by railway may, of course, avail themselves of the tourist system.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The Committee of this Society offer for competition by members of the South Metropolitan photographic societies, at their Exhibition to be held in November, 1892, the following medals:—Silver medal for the best photograph shown, irrespective of size; bronze medal for the second best photograph shown, irrespective of size; silver medal for the best set of six lantern slides; bronze medal for the second best set of six lantern slides. Entrance fee, payable only by non-members of the South London Photographic Society, 2s. 6d. each competitor. Among the rules for competition are the following:—Photographs for competition at the Exhibition shall be from negatives taken since the date the competitor was elected a *bonâ fide* member of one of the South Metropolitan photographic societies. The term "South Metropolitan photographic society" includes any photographic society whose meeting-place is situated within the South London postal district. Any member of the South London Photographic Society who is successful in obtaining an award shall present a copy of the photograph to the Society's album. The date and place of exhibition will be announced shortly. Entry forms can be obtained from the Secretaries of any of the South Metropolitan photographic societies, or of Mr. Chas. H. Oakden, Hon. Secretary, 51, Melbourne-grove, East Dulwich, S.E.

JOURNAL OF PHOTOGRAPHY.

No. 1679. Vol. XXXIX.—JULY 8, 1892.

OPENING OUT THE FIXED STOP OF A LENS.

It may be taken for granted that the maker of a lens is, or ought to be, the best judge as to the largest diaphragm that should be employed with it. Some persons, however, are so constituted as to imagine that they, as the users of the lens, are better competent to decide what suits their special requirements than the manufacturer of the tool. And there is much that may be said on both sides. Our remarks, it may be observed, have reference to that class of lenses, whether single or compound combinations, in which the diameter of the largest stop is smaller, sometimes considerably so, than that of the lens itself, a characteristic usually much more pronounced in wide-angle than in narrow-angle objectives. Such lenses are mostly of a deep meniscus form, which is inimical to the transmission of a large bundle of rays to a focal point, and hence the necessity of limiting the diameter of such a bundle by the agency of a small stop.

The optician, by trial, ascertains the maximum size of aperture that lessens spherical aberration to such an extent as to ensure sharp definition, and he decides upon that as the largest, or fixed, diaphragm in the mount, supplying smaller ones to extend the central sharpness over the whole field, or as much of it as may be thought necessary.

There are some users of lenses who think that the opticians draw, as it were, too fine a line in the determination of the definition; they would prefer a softer, less crisp degree of sharpness, obtainable only by the power to employ a larger aperture, coupled, as this is, with the incidental advantage of a greater degree of rapidity, by an increase in the illumination. We could mention several who are of this way of thinking, amongst them being Mr. Stillman, of Rome, who has just sent us a large collection of negatives, illustrating advantages accruing in his practice from opening the fixed aperture in his concentric lens from *f*-16 to *f*-11, which represents an increase in rapidity of working exceeding one hundred per cent.

For portraiture, especially if the heads are to be moderately large, and also for producing certain "naturalistic" effects in landscape work, this enlargement of the optician's fixed stop confers an undoubted advantage, a doctrine we have many times enunciated; but, when we come to consider that the largest aperture of this particular lens giving crispness (we are judging by our own one) would be more fittingly estimated at *f*-19 than *f*-16, we think that the makers act prudently and in self-defence in not sending them out with larger stops. If photographers were, as Mr. Stillman is, educated to employ their lenses with judgment, then no harm would be done by placing in their hands the giant's power of employing any aperture, however large, they choose; but opticians, out of regard to their own reputations, cannot afford to dispense such a power, for it need scarcely be said that the rank and file of camerists estimate the good quality of their lenses by the sharpness of the pictures produced by them. We have known a lens of undoubted excellence returned on the maker's hands because with full aperture, one of great angular width, it did not cover so sharply to the edges as another of less excellence by a different maker, but having a small central aperture. We, therefore, think that it will commend itself as a prudent step for opticians not to place their reputations at the mercy of babes and sucklings in the art whose knowledge of lenses is, at the commencement of their career, invariably of a low order. It is time enough for them, and even then under protest, to give a larger working aperture than that dictated by their own judgment when such a thing is demanded by one whose knowledge of his requirements, and the conditions under which the power should be applied, render it safe to place such in his hands.

SOME POPULAR IDEAS OF PHOTOGRAPHY.

What photography does and is doing for the progress of mankind in the arts, sciences, and manufactures, is perhaps known only within a small and restricted circle, notwithstanding that the camera and the dry plate have penetrated the homes of so many persons of all degrees of altitude on the social scale. Moreover, the opportunities which the non-photographic public have of correcting certain prevalent and erroneous ideas as to the supposedly narrow field in which modern photography finds its applications are not easily available; and, were it otherwise, it is doubtful if the spirit of inquiry is rooted deeply enough in the minds of people of average intelligence to prompt them to ascertain for themselves the exact position which photography holds in the ranks of latter-day knowledge.

Many people of the class we have just pointed at are, we have observed, prone to draw false conclusions in regard to photographic activity simply from a passing study of the contents of photographers' show-cases, and of the windows of those who make a speciality of retailing the counterfeit presentments of good-looking society ladies, shapely actresses, politicians, actors, members of the Royal Family, and the season's lions. For such as these the achievements of modern photography begin and end in the least important respect in which photography shines—that of shop-window portraiture.

Other persons, again, whom on most counts one is constrained to regard as tolerably well educated and informed, are influenced in the light esteem in which they hold possibly the most marvellous art of the Victorian epoch by a half-contemptuous contemplation of such decaying relics of the primeval era of

photography, as the shabby doorsman, the melancholy itinerants of the open heath, the seaside beach, and the rustic hostelry, and a consequently prejudiced estimate of their cheap and unskilful efforts to cater for their humble clients. Photography to such a class carries with it so strong a suggestion of being the exclusive prey of those known on the other side of the Atlantic as cheap Johns, that, unconsciously maybe, they become fatally unfitted to realise that it has a great and glorious existence quite apart from any such lowly, if not unworthy, surroundings.

A third class, probably as large as the two already mentioned combined, grounds its estimate of what photography is, and is capable of, solely from an observation of the outdoor performances of the ubiquitous amateur, and particularly the exceedingly numerous off-shoots of the race sworn to the devotion of the hand camera.

Superficial observers form by far the larger class of the community, no matter from what standpoint we cast the net; and the same rule applies, as we have endeavoured in the previous paragraph to make clear, in respect of modern photography. It will be evident that the number of people who have only the most confined and incomplete ideas upon the exact part which photography holds in the advancement of human knowledge is extremely large. In all probability, an appreciation of this fact was in the mind of the editor of one of our Parisian contemporaries, when he lately dwelt upon the circumstance that so many amateurs of the present time simply took up photography as a means of recreation, and that between such and the band of earnest workers and investigators in the various branches of scientific photography the utmost possible distinction should be made. But, to be of any real welcome or value to scientific photographers, this distinction should exist in the minds of the cultivated public, a state of things difficult to create, for, unfortunately, lack of appreciation and discrimination between the trivial and the important in scientific matters is a public idiosyncrasy which is not easily eradicated.

Perhaps there is little or no ground for complaint that, as a picture-making art, photography has not, on the whole, failed to secure a fair degree of recognition from the critical and cultivated; but of its far larger and more important accomplishments in the spheres of science and technological industry there is, generally speaking, a most profound ignorance. The enormous aid it has rendered to the astronomer, the biologist, the microscopist, the medical man, and a long list of professors of other sciences which Professor Meldola very effectively referred to in his recent lecture, as well as to representatives of innumerable manufactures and liberal pursuits, is either not perceived, or lost sight of, by those whose estimate of what photography is and does is based simply on the trifling ocular evidences we have enumerated above. Hence they refuse to photography the dignity and esteem which it should surely possess, and ignorant journalists and others constantly fling witless sneers at an art of the highest utility and illimitable possibilities.

Photography has helped to advance many sciences. It has revolutionised engraving, it has aided art and educated those who practise it, it has created several industries and sustained many others, and it has contributed liberally to nearly every section of human knowledge. These and a hundred other things in its favour equally as cogent are not so well and widely known as they should be, a fact we should all bear in mind when next it is our fate to submit to the ridicule and contempt with which a good many otherwise excellent and intelligent people regard photography to-day.

Theoretical Predication of the Powers of Certain Compounds in Developing. — In the *Moniteur Scientifique*, earlier in the year, is a very important paper upon "Reducing Agents of the Aromatic Series which are capable of Developing the Latent Photographic Image," by Messrs. A. & L. Lumière (see page 440). We commend it to the notice of all our scientific readers. A great variety of compounds and their isomers are treated of, and their relations to known developers described. All the "new developers" are alluded to, as also others not yet brought into practice, but which are capable of being utilised for the purpose with a greater or less amount of usefulness.

Decolourising Solutions of Shellac.—It has often been asserted that a solution of shellac in spirit can be decolourised by filtering it through animal charcoal. Such, however, is a fallacy. No such treatment will remove the colour. What has been said with reference to a spirituous solution has also been reiterated with regard to aqueous solutions. Here, again, the suggested treatment is equally fallacious, as all are aware who have put it to the trial. We allude to the fact here because we have on several occasions had letters from correspondents on the subject of their failures, and another is now before us. Apart from decolourisation, aqueous solutions of lac are exceedingly difficult to make clear by filtration, through whatever medium that may be performed.

The Next Solar Eclipse.—In the current number of *Nature* will be found an article giving detailed maps and particulars regarding the solar eclipse which will take place on April 15 and 16 next year. The line of totality will be seen to pass through South America and across tropical Africa. The American photographers will probably photograph from the Chilian district, while, probably, both French and English observers will work from stations on the Senegambian coast. The eclipse will probably be very widely observed, not only because the shadow of the moon passes over such a great stretch of land, but because the phenomena occur at a time when a sunspot maximum is approaching, when the sun's atmosphere will be more disturbed, more striking corona effects observed.

Colour Vision.—The returns issued annually prove very clearly that many of the candidates for the marine service are, more or less, colour blind, that is, they are unable to distinguish between certain colours and others. Now, this defect in vision often exists where it is not suspected. On the other hand, some persons are supposed to suffer from it where it has no existence at all. This sometimes arises from their not being able to name the colours properly, although they can distinguish them rightly enough. Some persons, for example, would call some shades of blue purple, or some shades of green blue, and so with other tints, yet they are perfectly able to distinguish between them all. A writer in a recent number of a contemporary, advocates, as a test for colour vision, the matching of colours without reference to their names. This idea seems to be a good one, if only as a supplementary test.

Election Portraits.—Those professional photographers who acted upon the suggestion we made a few weeks ago with reference to portraits of the local candidates for the new Parliament have, in most cases, no cause to complain. Indeed, some have written, thanking us for the "tip." At no previous election has photography figured so conspicuously as it does in the present. This, to a great extent, is to be attributed to the facilities that modern processes offer for the rapid production of large numbers. "Process blocks" appear to have been the method most generally adopted, for the reason that they could be printed from in the press with ordinary type at a cheap rate. Some of the examples, however, are particularly unfortunate, not so much on account of the quality of the block, though in some instances these have been inferior, as to the printing. Half-tone process blocks require careful treatment and the employment of good paper. The paper and printing adopted for electioneering purposes is not of that high order that would make the best of a delicate half-

tone block, although sometimes we are told the price paid for it would warrant the best results. Alas! for those who have to pay.

The Kew Committee and Photography.—In the last issue, No. 309, of the *Proceedings of the Royal Society*, will be found the report, in full, of the Kew Committee, which treats, *inter alia*, of many subjects of photographic interest. We learn from it that a new and simplified method of taking and comparing cloud photographs has been carried out, particulars of which, with examples of the cloud pictures, have been sent to the various committees interested in cloud photographs. We have no details of the kind of picture, but it would seem probable that, if duplicates could be purchased by the public, photographers would have a very ready means of obtaining cloud negatives, and in greater variety than is now possible. Of course, we are aware that numbers of such negatives of excellent character are now purchasable at the dealers'; but it is evident that, the greater the variety, the less the likelihood of two pictures being exhibited with the same atmospheric effects. We may say that our sympathy is entirely with those who prefer to take their own cloud negatives direct from nature; yet we cannot shut our eyes to the fact that a large and increasing number of photographers buy ready-made cloud negatives.

Lens Testing.—The report states that, "in the preliminary operations necessary to conduct the satisfactory examination of photographic lenses, Major L. Darwin, late R.E., has been associated with Captain Abney, and in accordance with his suggestions, a special camera, capable of working with lenses of four inches aperture, and thirty inches focal length, has been fitted up at the observatory. A photometer, on Abney's principle, has also been fitted for use in the testing operations. A detailed account of the apparatus and methods employed is in course of preparation by Major Darwin for publication. Meanwhile, circulars respecting the proposed scheme of examination and preliminary certificates have been printed, and 200 distributed among the leading opticians, manufacturers, and secretaries of all the best known photographic societies, both at home and abroad, to call their attention to the intended plan of examination."

Stations supplied with Photographic Apparatus.—The report also gives a list of places to which they have sent materials, and thus we learn that the observatories of Aberdeen, Lisbon, Mauritius, Oxford, St. Petersburg, Stonyhurst, the metereological offices of Batavia, Fort William, and Valencia have been thus equipped from Kew. Among other things, a camera and requisite fittings for securing photographs of clouds and lightning have been sent for Mauritius.

Fixing.—In the discussions that have taken place at some of the leading photographic societies on the stability or otherwise of silver prints, the general opinion of the most experienced workers appears to be that more importance should be attached to the fixing of the prints than to their washing afterwards. In other words, a perfect fixing is far more advantageous than a perfect washing—that is, if either of the two operations have been negligently performed. The complete fixation of a silver print is only to be brought about by a prolonged immersion in the hyposulphite solution, which should be freshly made and in good quality, or preferably by the use of a second bath. Unfortunately, however, some prints, such as those printed from feeble negatives on weakly sensitised paper, will not stand this treatment without loss of tone and vigour. A printer in an establishment doing a large business recently remarked to us that, if modern prints were left in a fixing bath of the ordinary strength for more than ten minutes or so, they began to deteriorate rapidly in appearance. This used not to be the case, he said, with prints from the negatives of old made on the heavily sensitised paper used with them. If modern prints will not stand the operation of fixing, how can we expect permanence?

Bad Mounts.—Various causes are at different times assigned for the rapid fading of silver prints; one of the most frequent is the cardboard upon which they are put. It is frequently assumed that if the mounts are free from "antichlor"—hyposulphite of soda—they are safe. This is a mistake, as they may be perfectly free from that impurity, and yet contain such deleterious matter as would seriously affect any silver print put upon them. We were recently present at the unpacking of a rather large parcel of photographic mounts from a Continental factory that may contain no hyposulphite of soda, yet we should say they were quite unsuited for photographic purposes. They had evidently been packed while they were wet, and had "sweated" in transit. They had been perfectly dry on the surface, no doubt, but were damp in the middle, so that when unpacked they had a sour and sickening smell, showing that a fermentation had been set up from the moist paste in the interior of the card. Although the mounts showed no signs of mouldiness, there is no doubt that it would develop itself later on if they were kept in a moist, warm situation. What effect this would have on a silver print our readers need no reminding. Some time back we saw some "wood middles" that were to be used in making mounting boards that had been packed damp, or had become so in transit, that were quite mildewed in the centre of the bales. There is no question that mounts made of such material must sooner or later act injuriously on the silver image.

New Method for Detecting Chlorides or Bromides in Presence of Iodides.—It was only quite recently that we had occasion to describe a new mode for ascertaining the presence of the haloids, and again we have to announce a still further process, which, though bearing a superficial resemblance to plans already published, is quite new and easily carried out with regard to dry plates. Dating from the People's Palace Technical Schools, Mile End Road, Dr. D. S. Macnair writes, that when freshly precipitated moist silver iodide is heated with potassium bichromate and concentrated sulphuric acid no iodine is set free, but the precipitate readily dissolves, forming silver iodate, which is precipitated along with some silver bichromate in diluting moderately and cooling the solution. Silver bromide, when treated in the same way, gives silver sulphate, the whole of the bromide being set free, while silver chloride behaves like the bromide, giving free chlorine and silver sulphate. These reactions furnish an easy method of detecting chlorides or bromides in the presence of iodides. It is only necessary to precipitate with excess of silver nitrate, filter off, and wash the precipitate, and heat it with powdered bichromate and a little strong sulphuric acid. If any chloride or bromide is present, even with a very large excess of iodine, its presence is easily detected by the evolution of chlorine or bromine. Dr. Macnair is at present making further experiments with a view to determine the delicacy of the reaction, and also whether it can be conveniently employed for the quantitative separation of iodine from chlorine and bromine.

ADVANCED PHOTOGRAPHIC WORK FOR AMATEURS.

IV.

To those workers who experience real pleasure in mastering the minutest details of the various operations connected with photography, such as the development of their negatives, and who subsequently print the same themselves, instead of, as many now do, by sending them to some professional to have the work done, there must, of necessity, be a pleasure which is entirely unknown to the amateur of the "You-press-the-button-we-do-the-rest school." Still, even among those workers of the former class, it is but seldom that any of "such are found who even go as far as they might in the way of preparing and sensitising their own printing paper.

The ordinary albumenised and printing papers of commerce are so conveniently and easily acquired from any dealer, that the mere idea of an amateur preparing his own paper is never for a moment entertained. Here, again, however, we have an operation which is fraught with much that is interesting to an enthusiastic worker. Doubtless the ordinary albumenised paper of commerce is now supplied to the public in perfect condition (a condition which no tyro would be able to approach in the attempt to produce such). Still, there are other classes of printing papers than the highly glazed or double albumenised samples, which any amateur may prepare with much success—in fact, a class of paper which it is impossible to obtain otherwise than by preparing such oneself.

Of late years, for the larger sizes of photographs, such as, say, whole-plate and upwards, there has been a distinct advance made in artistic taste by the employment of matt-surface papers, such as bromide or platinotype papers of commerce; and doubtless the last-named, to a very great extent, has taken the place of the good old rough-surface silver paper so popular with workers of the old school of photography.

I have no desire or inclination to discard the use of or deride the beautiful results obtained with the aid of platinotype paper, but I often think it a pity that the good old plain salted paper should have been so unceremoniously set aside by those workers who aim at the production of prints of the very highest degree of artistic merit. No doubt the facilities afforded the public of obtaining ready-prepared printing papers that will keep, and the admirable manner in which the bromide and platinotype processes lend themselves in the way of furnishing neat demonstrations in the matter of enlarging and development before amateur societies, has much to do with their popularity; but, were the heads of our various amateur societies to give more attention to the practical demonstration of numerous almost-forgotten photographic processes, I am quite certain their members would profit thereby. How many amateurs of the present new school of photography ever prepared or sensitised a sheet of printing paper for themselves, or even ever saw such an operation done? And yet this forms one of the most important items in practical photography. I am quite aware that, were all amateurs compelled to prepare and sensitise their own printing material, the number of those who now practise photography as a pastime would soon be reduced to a very small number indeed, because not one in a hundred would take the trouble to go to the extra cost of arranging even for such simple little necessaries as would be required to undertake the work. Others, again, have an idea that such is an operation of much difficulty; and, doubtless, this is true in a measure with regard to albumenised paper, but no worker of ordinary intelligence need hesitate for a moment in preparing and sensitising a supply of plain salted silver paper, the results from which will certainly compare with, if, indeed, not far surpass, the beauty of platinotype or bromide papers.

Admirably adapted for this purpose are the rough-surface drawing papers, such as Whatman's, and, when the samples known as snow-white are procured, an amateur could not select a more convenient paper to try his 'prentice hand upon in the way of preparing his own printing paper.

Let any one, therefore, desirous of undertaking this interesting part of photography procure such a sample of paper, and then proceed to make a salting solution as follows:—

Into a jam-pot place thirty ounces of clean cold water, then add forty-five grains of chloride of sodium and forty-five grains of chloride of ammonium; dissolve, and add forty grains of gelatine; place the jam-pot in a saucepan of warm water till the gelatine is incorporated with the solution; then set aside to cool by pouring the same into a flat porcelain dish of larger dimensions than the pieces of paper it is intended to prepare.

A convenient method for any one to follow who undertakes the sensitising of paper on a small scale is to cut up the paper into sizes slightly larger than the negatives to be printed from, and then immerse singly each piece in the salting solution for at least five minutes. This is best done in close proximity to a good kitchen fire, in front of which the homely "winter dykes" are placed, and, having bent some good-sized pins into the shape of fishing-hooks, attach them by fine threads to the cross bars of the clothes-horse. Each sheet of paper is then one by one removed from the salting solution, and held up at the corners by means of the hooks, and dried somewhat rapidly in front of the fire. When quite dry, they are placed away between sheets of clean blotting-paper, and are ready at any time for sensitising by means of the ammonia-nitrate-of-silver solution, prepared as follows: Dissolve one ounce of nitrate of silver in nine ounces of pure water; take three ounces of this solution, and add to same strong liquor ammoniæ until the oxide of silver formed is redissolved, and the solution again becomes quite clear; then add this to the remaining six ounces of solution. Oxide of silver will be again formed; this must be allowed to settle to the bottom of the bottle, and allowed to remain there. When using, filter off as much solution as will be required; exercise a little care in this, otherwise there will be surface markings on the paper.

We will now suppose it is required to sensitise, say, half a dozen pieces of paper to yield prints from 10 × 8 negatives, the paper being already salted and cut to sizes somewhat larger. Each piece is taken singly, and a pencil mark is made on the back, whereby the sensitised surface may be distinguished. The pencilled side is then laid upon a flat board, and the ammonia-nitrate-of-silver solution is evenly and lightly swabbed on by means of cotton wool or flannel. A convenient way is to employ a piece of glass, about three inches wide, over which are folded two folds of swan's-down flannel. This is first soaked or damped in clean cold water, and allowed to dry before being used in contact with the silver solution. The paper being tacked down at the four corners to the board, a pool of silver solution, in quantity sufficient to well cover the surface of the paper without any violent rubbing, is poured on the centre. The solution is then evenly guided, by means of the swan's down, over the entire surface of the paper, care being exercised that the surface is not roughened, and that the solution is spread evenly. This is best done at night, by means of ordinary gaslight; the paper is then hung up by the pins as before in front of a kitchen fire, or other suitable warm place, and dried quickly. It must be borne in mind that paper so prepared will not keep good for any great length of time; if, however, placed between sheets of clean blotting-paper, it will keep quite fresh for some days; therefore it is advisable only to prepare as much as is required for immediate use.

In printing this paper, it will be necessary to print somewhat darker than is the case with ordinary albumenised paper; when printed, however, the operations are just the same, only a much weaker toning bath is employed, to which I shall refer in my next.

T. N. Armstrong.

JOTTINGS.

"Brum's" hope that, concurrently with the publication of his letter, an indignant denial from Mr. W. Jerome Harrison would appear, disputing my charge that, under the pseudonym of "Talbot Archer," and in a journal published at the conveniently safe distance of some three thousand miles or so, Mr. W. Jerome Harrison had stabbed and derided the Photographic Convention of the United Kingdom and its chiefs in an un-English, unmanly, and unjournalistic manner, was not realised. I do not think "Brum" expected that it would be, for, while he goes out of his way to make himself impertinent and offensive to me, anybody can see that his defence of Mr. Harrison is of that nature which is calculated to make the latter individual pray heartily to be saved from his friends. The fact is, Mr. W. Jerome "Talbot Archer" Harrison cannot—nay, dare not—make the denial for which "Brum," in his malice, asks, for the good and sufficient reason that evidence establishing the identity of "Talbot Archer" with "Mr. W. Jerome Harrison" is far too plentiful to render such a disclaimer anything but the most forlorn and dangerous of enterprises. For the credit and good name of American journalism, I hope that, if he does not mend his ways, this *exposé* will result in the substitution for Mr. W. Jerome "Talbot Archer" Harrison of another English correspondent of *Anthony's Bulletin*; but if, unfortunately, Messrs. Anthony should fail to read these "Jottings," and thus have no opportunity of sending "Talbot Archer" to the right-about, I shall make it my business to keep a sharp eye on his fortnightly lucubrations, with the view of keeping your readers informed of the future goings on of "Talbot Archer." This, of course, assumes, Mr. Editor, that I myself do not meet the deplorable fate of being sent to the right-about from your own pages. [Exactly; so be careful.—Ed.]

I have tried some of the new Eastman gelatine-chloride paper; but as there are several other emulsion papers in the market, and as I wish to remain good friends with the Editor and Messrs. Greenwood & Co., I am not going to say anything about it which would lay me open to the imputation of having smuggled into this column any opinion of a laudatory, or advertising, nature. One thing in connexion with the new paper, however, strikes me as being such a good idea that I ask leave to single it out for mention, in the hope that it will be imitated by other manufacturing houses. I allude to the fact that for the humble shilling one can obtain packets of the paper of any standard size from quarter-plate up to 12 × 10, the aggregate area of the paper in one packet being equal to that of any of the others, larger or smaller. Few photographers would find it difficult to afford a shilling for six, say, 10 × 8 or four 12 × 10 pieces of paper, whereas perhaps, if the paper were only sold in packets of one dozen sheets at the same rate, the inducement to purchase, as well as the convenience, would not be so great.

The process of toning silver prints on plain paper by converting them into silver sulphide, described by Mr. C. D. West at the May meeting of the Photographic Society of Japan, is hardly entitled to be called "new," except perhaps the novelty be the employment of sulphuretted hydrogen instead of potassium sulphide. Of the stability of the image of sulphide of silver, as well as the beauty of tone that may thereby be obtained, there is such a general agreement that I am surprised such a system of toning is not more largely adopted both for transparencies as well as paper prints.

The plate-makers must look upon the Holborn Camera Club with an eye of approval, for, according to the report in the JOURNAL of June 24, the Club had an outing on June 18 to Pinner and Ruislip, "where a very charming afternoon was spent in spoiling plates." But, if the members of the Holborn Camera Club are not capable of utilising dry plates in any other manner than by spoiling them, why go to the time, trouble, and expense of a journey to Pinner and Ruislip, and waste a very charming afternoon in pursuit of that object? Or is this, after all, only a little secretarial joke? If it is, what do the members think of it?

I was pleased to see that Mr. J. Pike discounted the value of mercuric chloride in assisting to remove iridescent stains sometimes produced in ammonia development, a reduction process with potassium ferridcyanide and hypo, such as he indicates, being obviously more rational. The iridescent stains he speaks of are not, I fear, producible by ammonia alone, for I have myself been troubled with them when using sodium carbonate as the alkali. It is, I believe, an undoubted fact that iridescence is usually a sign of age in a gelatine plate, which often does not need the assistance of the developer to make it visible. The worst case of iridescent markings with which I was ever troubled, however, was shown in some plates which had not left the maker's coating room a fortnight. Those plates before development had "gone" to the depth of about an inch round three sides, and, after development, looked like nothing so much as polished metal of a bluish tinge.

The editor, in pointing out the uses of the front combination of a lens of the rapid symmetrical type in allowing of a greater focal length being obtained than when the back combination, as is often done, is used, gives a hint which deserves noting and remembrance. Even were all compound lenses really symmetrical, which as a matter of fact they are not, the circumstance that either the front or the back combination can be employed at will confers a property upon this kind of lens the existence of which is not generally recognised. This is, that the one lens can be converted into practically three objectives of different foci.

I am sure, in saying that we all deplore the lamentable balloon accident at the Crystal Palace in which Mr. Cecil Shadbolt, the worthy son of a worthy father, so nearly lost his life, I am only voicing a general opinion. Both gentlemen have done good work in the field of photography, and are entitled to our warmest sympathies.

COSMOS.

ART: ITS MISSION AND CATHOLOCITY.*

EACH one of us is a curious admixture of Useful and Fine Art; and, as a man's temperament is, so will the Useful or the Fine preponderate, so will his path in life be chosen. With his construction of iron and stone the artist will bridge for his fellow-beings an arm of the sea, or with his palette and brush he will bridge the narrow gulf between the Real world and the Ideal. We are each possessed by this Ideal, consciously or unconsciously, and in working it out we show ourselves artists of great or mean capacity, just so far as our Ideal is essential to the period in which we labour, and just so far as it is made clear to those around us. It may be said that no work of art was ever produced that was not an effort on the part of the artist to translate the conception of his mind into a medium understood by his fellow-beings; but, "in the long way from the eye through the arm how much is lost!" his production will be the replica of his conception just so far as he is a skilful artist. It may be such a complete and luminous translation as shall be its own emancipation from art canons, or it may be a mere catalogue of form and colour. Looking back with critical eyes over the world's history the conviction is forced upon us that the aim and endeavour of Art is to give concrete form to this Will o' the Wisp Ideal. It is Art's one supreme mission in every age to stamp the Ideal of that age in its surroundings; and in the works of art of any period in the world's history we have an unimpeachable witness to the culture of that age and its customs; for to enable each age to make itself ineffaceable seems one of the truest offices of Art.

Yet the work of art can never wholly realise the Ideal of the artist; it can only be an approximation to it, for the artist must ever be hindered by the unpliableness of the medium in which he realises his conception; "but through his necessity of imparting himself the adamant will be as wax in his hands, and will allow an adequate communication of himself." It rests with his education and persistent effort to expand the arc of the pliability of his means of expression; the hammer and chisel of the Egyptian hieroglyphist became, through long use and careful education, the facile medium of the Grecian sculptor; and the painter's brush has become, next to language, the most eloquent of any means of imparting ourselves. To what extent photography can be made available as an art of expression rests with its disciples, yet we cannot look around the walls of any photographic exhibition and doubt that a great future exists for it in this respect. All bold endeavour to utilise photography as a means of conveying an artist's conception should be welcomed and tolerated, as tending to increase the arc of its pliability. Much has already been done in this direction, thanks to those bold spirits who dared the first departures from the mechanical photography of former days, and there are in existence, in no meagre quantity, pictures done by photography before which criticism is dumb, because the conception of the artist has been so clearly imparted as to leave no room for speculation.

When an artist works out his ideal and places it before his fellow-beings by means of the Fine Art in which he works, it is with the reasonable hope that it will afford pleasure or instruction to those who have ideas and views resembling his own; but in all communities of men there will be diversity of opinion and taste. The same landscape, the same human face, the same phase in our social life will be different for you and me by the difference in our temperaments; and, when we have issued to the world our separate interpretations of the evening landscape, the human face, or the social phase, there will be the difference between the two of our individuality, which is a birthright no one can take away from us. The picture that attracts and is full of meaning to one is to another devoid of interest and beauty; yet does that not give him the right to say it should not exist. All works of art that exist have meaning and beauty in them for some one—it is their warrant of existence; it is nothing that their meaning be hidden and their beauty unfathomable to those who lack that sympathy which is the key to their use. "Every genuine work of art," we are told, "has as much reason for being as the earth and the sun."

In conclusion, I would plead for a broader view of Art, and a more liberal appreciation of its functions. Art is not solely pre-Raphaelism, or Impression, but of sufficient universality to include both these phases, and a thousand others beside. It is not the painter only who is an artist, but the musician, the littérateur, the orator, and, if he chooses, the photographer. A work of art is not, or should not be, produced as an exemplification of the tenets of particular schools of treatment, nor should it be a picture-lesson in art rules; for then will it become, what only it deserves to become, a battlefield for vituperative critics. *It should be the closest possible approximation to the conception of the artist's mind that his method of expression, aided by his own culture, will allow.* Then will Art fulfil its mission, as "a wonderful expression through stone, or canvas, or musical sound of the deepest and simplest attributes of our nature, and therefore most intelligible at last to those souls who have these attributes."

GEORGE T. HARRIS.

* Concluded from page 426.

MAGIC LANTERN MATTERS.

[South Manchester Photographic Society.]

ON the present occasion I shall not have much to say about the magic lantern anterior to the introduction of Marcy's Sciopticon (from America) by the late W. B. Woodbury. Of course it is quite true that we had lanterns before the sciopticon, and these were of two types, one for burning oil which was nothing more than a toy—and a poor one at that—quite unsuitable for anything more than showing painted slips on screens very little larger than a pocket handkerchief; the

other was a big clumsy oxyhydrogen lantern, which was chiefly used for Sunday-school meetings, mechanics institutions and by a few private exhibitors and lecturers. We had occasionally a good deal of talk about using the lantern for educational purposes, but there was very little practical work done in this direction; not many amateur photographers made lantern slides, or paid much attention to them in those days. But there were a few commercial firms who produced lantern slides, and the introduction of the sciopticon must have vastly increased their business, for that beautiful little instrument not only filled up the gap between the already existing instruments: it did more, it was capable of taking the place of both; with its two-wick oil-lamp it was possible to exhibit photographs in the drawing-room on from five to six feet and up to seven-feet screens without much trouble, and also by the same instrument, using limelight, the largest screens were just as brilliantly illuminated as by the most ponderous lantern ever constructed; indeed, the sciopticon came at the right time, it was just the very thing that was wanted, and it became so popular as to be almost a part of every amateur's paraphernalia.

I believe it to be a fact that Woodbury did take provisional patent protection for the sciopticon lamp in this country, and that during the first year they were placed upon the market over 400 were supplied, but by an oversight, or we may say neglect, for Woodbury was not a business man, the patent was not completed. Other firms took advantage of this, and very soon placed similar lanterns before the public at a slightly reduced price. I am informed that one firm alone supplied over 1000 of these in the following year. We had not long to wait before several so-called improvements were introduced and patented, but it may be said that nearly all the oil-burning lamps for lantern purposes used to-day are more or less the progeny of the sciopticon.

The sciopticon was originally constructed to burn two one-and-a-half-inch wicks, placed edgeways to the condenser, and with the exception of some improvements in the combustion chamber, made by Mr. George Smith, the present proprietor and manufacturer, it remains in its original state. Some of the so-called improved lamps are made to use three, four, and as many as five wicks, and these up to two inches and two and a half inches wide, either placed parallel, converging, or diverging, and some again take other forms, the intention being to increase the illuminating power.

Now, if it were necessary, I could give my experiences of many years with nearly all these multiple wick-lamps, and down to the latest patent before the public; but, to be brief, I see no advantage in them for the purpose for which oil-lamps are suitable. There undoubtedly is in some an increase in the size of flame; but for lantern purposes a large volume of flame is not required. It is intensity that is necessary, and the intensity must be in the right place, which is the focus of the condenser, and is confined to a very small area, and it can be shown to be a positive disadvantage to have more volume than is required. Then, again, the enormous heat given off by some of these powerful lamps, resembling a roaring furnace, is another very great disadvantage. Added to this is the difficulty to keep the wicks burning evenly, by reason of unequal combustion, for very soon the wicks begin to "fork," one flame gets higher or lower than the rest, the thing begins to smoke, to smell, the light goes bad, and the whole affair has to be readjusted; but with the two-wick lamp there is none of these troubles. It is quite easy to adjust the lamp at the commencement, as not to require the slightest attention for three or four hours.

It has been stated by some amateur lanternists that with So-and-So's or somebody else's lamp they have exhibited ten-feet pictures, and we know there are some gentlemen who are always cleverer than everybody else, and sometimes these gentlemen are so carried away by their enthusiasm as to believe they have done something big, or, at any rate, to tell us so. I can light my dining-room by a farthing candle, but I do not think you would care to be entertained at dinner by such illumination. Then, we have somebody's lamp compared to limelight. Well, of course, we can compare the light of a candle to the electric arc light; but for *equality* of illumination the comparison is a very poor one.

The limit in size of picture shown by any oil lamp is, in my opinion, six feet square where photographs are the pictures, but it is possible to select a few photographs of certain subjects that might be tolerated to seven feet, and perhaps more, but after seven or eight feet the blow-through limelight becomes necessary, and this may be used up to ten or even twelve feet, and after that the mixed jet, with oxygen and hydrogen under pressure, is indispensable. Ether may be used in place of hydrogen or coal gas, but I see no advantage in its use in any way.

The oil-lamp, then, as I have stated, is only suitable up to six-feet screens, and the question comes now, is six feet large enough? The answer to that is, it depends where it is to be used and the size of the audience. I have given a good deal of pleasure to private friends at home by even a less picture, but in a private drawing-room or a dining-room it is not always convenient to fix a six-feet screen, and very often when it is convenient there is either a fire burning in the room or some abominable reflections, that cause a good deal of trouble by interfering considerably with the results. All these objections are dispensed with by using a transparent screen such as I now introduce. In this little waterproof case, not unlike an umbrella-cover, except that it is a little longer, is a roll of a particular kind of semi-transparent paper three feet eight inches wide. The outer end of it is attached by six drawing pins to a wooden lath five-eighths of an inch square, having suitable fittings for attaching to two light stands, also contained in the waterproof case. The screen, as you will see, can be erected on one end of a dining-room table in three minutes; and, if the table is long enough, the lantern can be placed at the other end. The audience sit in front, and I think you will be surprised to see how beautiful pictures look when projected in this way. The reflections from the house-fire do not interfere with the results in the slightest degree. We may even permit a tolerable light in the room, and you may strike a match to light your cigar without seriously impairing the brilliancy of the picture. And, now that all is ready, you see a beautifully illuminated picture three feet six inches square by a sciopticon, and which I maintain is large enough for most private-house exhibitions, or even in a small schoolroom, where the audience is not too large.

I am not advocating small screens in preference to large ones, for all depends upon circumstances; but I do prefer a well-lighted small screen to a large one with inferior illumination, and especially so when we can get to the best position from which to view the pictures; and here another matter may be of interest.

The lanternist inquires what is the most suitable size screen for a certain size room? and the audience ask which are the best seats to see the picture from? To say that the screen ought to be in proportion to the size of the room is the general way of putting it, and to sit about the middle of the room is the usual reply to the best position.

Now, it is an established fact, which was recently demonstrated at the Stereoscopic Club, that the most correct position from which to view any photograph is at the angle at which the photograph was taken. Thus, if we make a picture by a twelve-inch lens, and we wish to appreciate size and perspective correctly, we must view the picture at twelve inches from the eye. To examine it at a nearer distance is equal to it being taken by a longer-focus lens than twelve inches; and to see it at a greater distance gives the impressions of one taken by a shorter-focus lens. Then, if we make quarter-plate negatives by a five-inch lens, to see it correctly we must either use a magnifying-glass or a stereoscope, or we may magnify it by the lantern; but the principle is just the same. If we make lantern slides by contact from quarter-plate negatives taken by five-inch lenses, and mask these down to $2\frac{3}{4}$ inches, as is usual, and then project these slides to 6 feet, we have a magnification of 26 diameters; then 26 by 5 (focus of lens) gives 11 feet. If we project the slide to 12 feet, or about 52 diameters, this, multiplied by 5, will show us that, at 22 feet, we should see the pictures at their best; and, from what has now been said, it will be understood how incorrect it is to make lantern slides which are to be shown in series from negatives taken by lenses of different foci, or what comes to the same thing, is making contact slides from quarter-plate negatives and other contact slides from portions of whole-plate and even larger negatives.

At a lantern exhibition, not very long ago, a series of slides of Haddon Hall were shown. The photographer had used a nine-inch focus lens for most of the exterior views, but for all the interiors a five-inch lens was used. I well remember the view from the terrace steps, showing the main front of the building, with the ball-room windows; and the next view was the interior of the ball-room. It looked so very large, that no person in the world who did not know the architecture could have imagined a room of such dimensions to be contained in the building we had just seen upon the screen. It was as ridiculous as for an architect, to submit unfigured plans of the rooms in a house all drawn to different scales, to fill up the paper, and where the bath-room and the w.c. might be shown the same size as the dining-room, no true idea could be formed from such drawings or such photographs.

A similar misuse in lenses was made by a friend of mine who went to Norway last year; he had a half-plate camera, and a seven-inch rapid rectilinear lens. About half the number of his pictures were taken by this lens, and the others by one of the combinations of the lens only, which would be about fourteen inches focus. He said it saved him the trouble of walking or climbing to places where, say, a

waterfall would have been too small to fill his plate if taken by the seven-inch combination; the result is, that nearly all the waterfalls in Norway, judging from his pictures, are the same size, and no true appreciation of size or distance is possible from his *series* of pictures.

About the artistic side of the question, I am not here to-night to discuss, though admitting there may be circumstances where, on the same size plate, a seven-inch lens will be better than a five-inch, or *vice versâ*, but I repeat, and with emphasis, that the too frequent use of lenses of great disparity in focus for lantern slides is a mistake.

It may be said in conclusion that the focus of the lantern objective has nothing whatever to do with the subject of this communication.

W. I. Chadwick.

CLOUD PHOTOGRAPHY.

Not to trespass too greatly on your space, I will briefly say, in reply to your correspondent "A. M. M.," that further experience has not led me to wish to qualify anything I have said in the paper to which you have referred him, and which gives a full answer (as you say) to his first four points.

As to the use of a Nicol prism, I am not aware of any extended series of experiments in point. The apparatus would necessarily be rather clumsy, and, if a reasonably wide angle of view were required, the cost of the Nicol would be very great, far more than the mirror, and without any corresponding advantage.

Ordinary dry plates and direct exposure may be made to yield good results where the clouds are dense and stand against a clear deep blue sky; but if the sky is hazy, or if the clouds are thin, it is comparatively seldom that the exposure can be correctly timed.

Some excellent pictures have been sent to the British Association Committee on Meteorological Photography which have been taken on orthochromatic plates, but no very trustworthy conclusion can yet be drawn as to the comparative merit of the method. At the last *soirée* of the Royal Society, some beautiful pictures were shown which had been taken at the Vatican Observatory under the direction of the Rev. Padre Denza. Some of these were taken by this method, but without a coloured screen.

I see that M. Angot, in a report presented to the Société Météorologique de France on June 7, says: "The best results are obtained with coloured screens; nevertheless, the ordinary screens are insufficient. The following formula, due to M. Léon Vidal, gives every satisfaction. In a little glass trough with parallel faces, a solution is introduced which has the following composition:—

Sulphate of copper	175 grammes.
Bichromate of potash	17 „
Sulphuric acid	2 c.c.

These are dissolved in from 100 to 500 cubic centimetres of water according to the thickness of the trough and the results to be attained." Lumière's orthochromatic plates are used with this screen.

Dr. Riggenbach directs that exposure (direct) should be so timed and development so carried out that the image of the cloud should appear while the sky remains clear. The faint image thus obtained should then be intensified by the sulphantimoniate method, but that, if half tones are required, some other intensifier must be used.

I must say I am at a loss to see how such a method could yield the beautiful results Dr. Riggenbach has obtained, but it is rash to theorise in such matters, and I have not yet experimented upon it.

One thing I have done is to experiment with *slow plates*. "A. M. M." makes no reference to this method, but he will find it well worth trying. With my black mirror and Mawson & Swan's photo-mechanical plates, or with plates coated with the emulsion the same makers use for lantern slides, I have obtained negatives of the thinnest and most difficult clouds which, for clearness of definition of the cloud forms, could not be surpassed. Negatives taken on ordinary plates by the same method often require intensification, but the slow plate, cautiously developed, gives excellent bromide or transparency prints at once.

Slow plates exposed direct may also be made to give satisfactory results, but the adjustment of stop and exposure I find more difficult than it is with the mirror.

I have not yet been able to make a comparative test of the merit of orthochromatic plates, but I do not think a rapid brand would be found satisfactory. A slow brand would probably give good results.

I am afraid these notes are somewhat hasty and disjointed, but they will show "A. M. M." that doctors differ as to the respective merits of their methods. Probably black mirror, coloured screens, orthochromatic plates, or even slow plates, can, in practised hands, be made to yield equally good results. But the question is, Which is easiest? So far as my experience goes, you could hardly have an easier task than to take a cloud effect with the black mirror and a slow plate. I use a stop *f*-11, and vary the exposure from half a second to perhaps one-tenth, according to the light. Heavy clouds require longer exposure than cirrus, but a little practice will soon give better guidance than any amount of verbal advice.

In conclusion, as Secretary of the B.A. Committee on Meteorological Photography, I should be most happy to give "A. M. M." (or any one else who wishes to take up cloud photography) any further information in my power, or even an opportunity of seeing my apparatus and negatives.

Arthur W. Clayden.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

Edinburgh Meeting.

The Convention proceedings commence on Monday, July 11, in the Hall of the Royal Scottish Geographical Society (kindly granted by the courtesy of the Trustees for the Board of Manufactures), Queen Street, Edinburgh.

Details of Excursions.

Tuesday, July 12.—Melrose and Dryburgh. Leader, Mr. Hippolyte J. Blanc, A.R.S.A. Train leaves Waverley Station at 9.20 a.m., and Melrose on return at 5.59 p.m.; 10*s.* 6*d.* each, including railway fare, admission to Melrose and Dryburgh Abbeys, drive to Dryburgh and back, and luncheon; lunch at the George Hotel, Melrose, at 1 p.m.; drive to St. Boswells at 2 p.m. Full particulars will be posted in the meeting-room on Monday, July 11. At Melrose: The abbey, east and south windows, portion of cloister, &c. At Dryburgh: The abbey, Norman door, cloister court, St. Mary's aisle, Sir Walter Scott's tomb, views on river Tweed.

Thursday, July 14.—Excursion A, St. Andrews. Leader, Mr. J. D. Cox. Train leaves Waverley Station at 9.35 a.m., and St. Andrews on return at 3.30 p.m., arriving in Edinburgh at 5.25 p.m.; railway fare, 4*s.* 8*d.*; lunch at "Cross Keys" Hotel at 1 p.m. St. Andrews Cathedral, St. Regulus' Tower, views in harbour, &c.—Excursion B, Dunfermline, &c. Leader, Mr. J. M. Turnbull. Train leaves Waverley Station at 10.15 a.m., and North Queensferry on return at 3.39 p.m., arriving in Edinburgh at 4.5 p.m.; railway fare, 1*s.* 11*d.* Dunfermline Abbey; Inverkeithing, old houses in street; North Queensferry, views of Forth Bridge.

Friday, July 15.—Excursion A, Dalmeny and Cramond Bridge. Leader, Mr. J. R. Roddick. Coach from Waverley Steps, Princes Street, at 10.30 a.m.; other coaches about every half hour; fare, 1*s.* each way; luncheon, Cramond Bridge Hotel, 1.30 p.m. At Dalmeny: Dalmeny House and Barnbougle Castle, the residences of Lord Roseberry; views in park, including Forth Bridge in distance. At Cramond: Old Bridge, Old Mills, Cramond Ferry, and numerous fine views on river Almond. Members desirous of doing part of this excursion could join in the morning and return to Edinburgh to luncheon, or could join the excursion for the afternoon at Cramond Bridge Hotel at 2 p.m.—Excursion B, Roslin and Hawthornden. Leader, Mr. W. Brown. Coach from Waverley Steps, Princes Street, about 10.30 a.m.; other coaches at intervals during the day. At Roslin: Chapel, exterior and interior views; Roslin Castle from dell; and many fine views on the river Esk, in Roslin Glen, and in the grounds of Hawthornden.

General Information.

Application for membership should be made to the Hon. Sec. or to the Hon. Local Sec. The subscription is 5*s.* per annum, and is due on the 1st of January of each year. Ladies are eligible for membership.

An exhibition of novelties in photographic apparatus will be held at the Hall of the Royal Scottish Geographical Society daily from July 12 to 16 inclusive, between the hours of 9 a.m. and 10 p.m. Members must produce their membership ticket on entering.

The annual meeting will take place at the Hall of the Royal Scottish Geographical Society at 10 a.m. on Wednesday, July 13.

The group will be taken, weather permitting, in Princes Street Gardens on Wednesday, July 13, at noon.

The Royal Hotel and the Waverley Temperance Hotel will be the Convention head-quarters during the meeting.

The dinner will be held at the Waterloo Hotel, Waterloo Place, on Friday evening, July 15, at 6.30 p.m., followed by a smoking concert Tickets, 5*s.* each (including attendance but exclusive of wine), from the Hon. Secretaries.

Members on arrival are requested to enter their names, full address, and where staying in Edinburgh, in the signature book in the hall.

The rooms of the Edinburgh Photographic Society at 38 North Castle Street have been kindly offered to the members of the Convention for changing or developing their plates. The following dark rooms have also

been placed at the service of members of the Convention:—Mr. A. H. Baird's, 15 Lothian Street; Mr. J. Buncle's, 7 Hope Street; Mr. William Hume's, 1 Lothian Street; Mr. James Stuart's, 34 Frederick Street; Mr. J. M. Turnbull's, 6 Rose Street; Mr. T. Haddow's, 2 Maitland Street.

Permission has been obtained to photograph the following places:—Edinburgh from Calton Hill, before 8 a.m.; Edinburgh from Castle, in the afternoon; Sir Walter Scott's monument, any time; Castle from Princes Street Gardens, morning or evening; Castle from Grassmarket, before 9 a.m.; John Knox's House, High Street, afternoon; St. Giles' Cathedral, east end, before 9 a.m.; ditto, west end, after 2 p.m.; ditto, interior.

A Handy Guide to the City and District, with maps by Bartholomew & Son, can be had at the meetings of Convention, price 1*s.* each.

SYNOPSIS OF PROCEEDINGS.

Monday, July 11.—Reception at 6.30. Presidential address at 7.30. Optical lantern and opening of exhibition at 9.

Tuesday, July 12.—Excursion to Melrose and Dryburgh.

Wednesday, July 13.—General Meeting at 10 a.m. Meeting of General Committee at 11. Convention group at 12. Papers (3 to 6 and 8 to 10 p.m.): *Individuality in Photography*, H. P. Robinson; *The Art of Photography in relation to Painting*, A. Burchett; *Amateur Photography in America*, Miss Catharine Weed Barnes; *Orthochromatic Photography IV.*, C. H. Bothamley; *Photography in relation to Medical Record and Demonstration*, A. Pringle; *On the Training of Photographers*, E. A. Howard Farmer; Paper by W. K. Burton.

Thursday, July 14.—Excursions to St. Andrews and Dunfermline. Papers (8 to 10 p.m.): *The Use of the Colour Screen in Landscape Photography*, Charles L. Mitchell, M.D.; *Direct Silhouette Portraiture* (with lantern illustration), J. Cox Cox; *How to look at Photographs*, F. M. Sutcliffe.

Friday, July 15.—Excursions to Dalmeny and Cramond Bridge, Roslin and Hawthornden. Dinner and smoking concert, Waterloo Hotel, at 6.30 p.m.

Saturday, July 16.—Council Meeting at 10 a.m.

REDUCING AGENTS OF THE AROMATIC SERIES WHICH ARE CAPABLE OF DEVELOPING THE LATENT PHOTOGRAPHIC IMAGE.

(*Moniteur Scientifique.*)

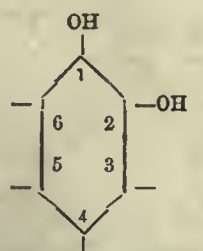
THE authors have endeavoured to apply to photography the conquests of chemistry, and to find a chemical theory for developers; from their observations, the following conclusions have been drawn.

1. For a substance of the aromatic order to be a developer of the latent image there must be in the benzinic nucleus at least two groupings of hydroxyl or two of amidogen, or at the same time a hydroxylic and an amidogenic group.

2. The preceding condition is necessary, but it only seems sufficient in isomerism.

For example, orcine will not develop; its isomeride, toluquinone, develops perfectly. Resorcine indicated as developer has no action in the state of purity. Caffeic acid, however,—

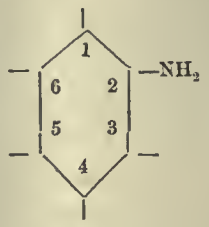
and pyrocatechin,—



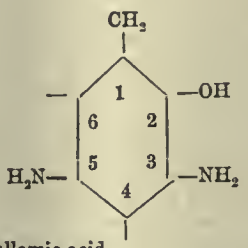
are developers. It is possible that other substances than the isomerides have reductive qualities, but these exist in all cases of isomeric relation.

3. The developing power may persist when in the molecule there are a greater number of groupings OH or NH_2.

Pyrogallic acid was already known; we may also mention diamidophenol,—



diamidocresylol,—



a triamidocresylol; gallamic acid.

4. When the molecule results from the welding of two or several benzinic nuclei, or of benzinic nuclei and others, preceding remarks are only applicable when the hydroxylic groups and the amidogenic exist in the same aromatic nucleus.

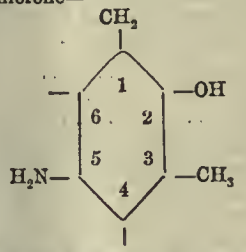
For example, benzidine has no action nor oxycarbostyryles, whereas paradioxyquinoleine acts.

5. The substitutions made in the group OH or the group NH_2 destroy the developing properties whenever at least two of these groups do not remain intact in the molecule.

For example, dimethyl-para-amidophenol does not develop, neither does dimethyl-hydroquinone. Guaicol, however, acts.

6. The other substitutions which may be made in the CH of the nucleus do not seem to suppress the developing power.

For example, hydrophlorone—



Podocarpic acid does not seem to annul the developing power. But the acid function seems to diminish it, for caffeic, protocatechuic, and amidosalicylic acids only develop with a strong base, the alkaline carbonates being no longer sufficient.

7. The preceding remarks only apply to the aromatic series.

Ethylendiamine and guanidine have no action. Phenylhydrazine is an exception; but, on the other hand, this compound is quite outside of the previous rules by its mode of formation.

The following conditions must be added to the above. The substance must be soluble in water, its solution little coloured, and the products of its oxidation in the bath must have little colour and not dye gelatine.

In a note in the June number of the *Bulletin de la Société Française de Photographie* the authors indicate the following formulæ for the application of para-amidophenol to the development of gelatino-bromide of silver.

I.

Water	1000 parts.
Sulphite of soda	200 ,,
Carbonate of soda	100 ,,
Para-amidophenol	12 ,,

II.

Water	1000 ,,
Sulphite of soda	200 ,,
Carbonate of lithia	12 ,,
Para-amidophenol	12 ,,

The first formula is very energetic, and is particularly suitable for instantaneous developments.

The slight solubility of para-amidophenol does not give the latitude in

the formulæ which pyrogallic acid presents, for example. But, *per contra*, the solution is preserved for a long time colourless and active.

Finally, in a recent communication to the French Photographic Society, Messrs. Lumière publish a comparative study on hydroquinone, para-amidophenol, and eikonogen. Leaving aqueous solutions of these three compounds in the air, the para-amidophenol oxidates first, then eikonogen; hydroquinone resists longest.

The product from oxidation of the para-amidophenol, probably quinonimide, is insoluble in water; the solution is not disturbed, but deposits a black soluble precipitate, which turns violet in ammonia or alkali and red in nitric acid.

With eikonogen, the solution is coloured deep brown, turning green in ammonia and red in nitric acid.

Finally, the oxidated solution of hydroquinone is reddish, becomes yellow in ammonia, and is discoloured by nitric acid.

These same products form in developing; those of eikonogen and hydroquinone dye gelatine yellow, which remains colourless in the case of para-amidophenol. At least twenty-five *clichés* can be developed with this last substance without finding any difference from first to last; whereas with the two others, as soon as some *clichés* have been developed, the others turn yellow.

These three compounds reduce soluble salts of silver, but have no action on haloid salts, except in presence of an alkali or alkaline carbonate.

The addition to the developer with para-amidophenol base of bromide of potassium or hyposulphite of soda, produces almost similar effects as with the other developers.

By the Reeb process, to fix the weight of necessary matter to reduce one gramme of nitrate of silver, the authors obtained the following numbers:—

Hydroquinone	0·07
Para-amidophenol	0·14
Eikonogen	0·30

It then requires twice as much para-amidophenol, and four times as much of eikonogen, to reduce the same weight of nitrate of silver. From a practical point of view these differences are of no importance, for the reducing agent is always in great excess as regards the salt of silver. Para-amidophenol, however, seems to present these advantages. It oxidates more rapidly, and, in consequence, is more energetic, and develops more rapidly. The products of its oxidation have no injurious effect on the image or gelatine.

The best proportions are, it seems, as follows:—

Water	500 parts.
Carbonate of potash	40 ,,
Sulphite of soda	100 ,,
Para-amidophenol	8 ,,

A. & L. Lumière.

AN IMPORTANT PATENT LAW CASE.

Skinner & Co. v. Shew & Co.

In delivering judgment in this case, on July 1st, Mr. Justice North said: I have to deal with the thirty-second section of the Act and the cases that have been decided upon it. Looking at those cases, it is clear that if the solicitor of a patentee writes to a person whom he believes to be infringing his patent, and threatens him with an action for infringement, that is a threat which the person to whom it is sent has a right to treat as a threat within the thirty-second section of the Patents Act, and to bring an action to restrain accordingly. He only does it at some risk, because the proviso at the end of that section runs that the section shall not apply if the person making such a threat with due diligence commences and prosecutes an action for the infringement of his patent, and it may be that if a person to whom such a letter is sent treats it as a cause of action, and brings his action upon it, he may find that his ground of action is cut from under his feet by, within a reasonable time afterwards, an action being commenced such as was threatened. That was the very case that arose in the case of the Combined Weighing and Advertising Company *v.* The Automatic Weighing Machine Company, but as a step in deciding that action the first thing decided was that the letter written was a threat. If it had not been so the rest of the decision would have been entirely unnecessary. The law has been so settled ever since the case of the Driffield Company *v.* The Waterloo Warehousing Company, reported in 31 Chancery Division. I found the law so settled, and I had to follow it, and I had in consequence, in the case of Barret *v.* Day, to hold that a letter, which I thought was a perfectly proper letter for a solicitor to write, saying that an action would be brought to restrain the infringement of the patent, addressed to the person infringing, I had to hold that that was a letter which did give a right of action, unless the proviso prevented it. In this case the correspondence which has been put in, is all that we have to consider, and the history of the case is shortly this, that on the 12th of February the Stereoscopic Company wrote to the defendants: "We have had submitted to us, with a view to placing it upon the market, a folding hand camera, which we send herewith. On looking at it carefully over, it struck us that in some points there were faint resemblances to your own Eclipse camera, and, as it would be quite contrary to our desire to in any way infringe upon your patent, we thought it would be very much better to submit it to you, and ask whether you thought it in any way encroaches upon your rights; not that we think it does, but, of course, we are always anxious to act honourably towards any other dealer in the trade." To that the defendants reply to the Stereoscopic Company: "We thank you for your kind letter of yesterday, and, in reply, beg to say that the camera shown is undoubtedly, in our opinion, an imitation of ours, and an infringement. We shall be pleased to see Mr. Humphreys" (he is a member of the Stereoscopic Company) "on Tuesday, as suggested, and shall by that time have taken further advice in the matter." A meeting took place. I have not heard what passed at it, but evidently a letter was promised, for on the 17th the Stereoscopic Company wrote to the defendants: "I have not yet received the promised letter, which places me in rather an awkward position, as we must do something definite in the matter at once. Can you send it per bearer?" "To do something definite," there obviously was replying to the plaintiff's letter, whether they could or could not take any of these cameras, or undertake to put them on the market. Then comes the answer from the defendants to the Stereoscopic Company of the 18th: "In reply to yours of the 13th inst., we beg to confirm our opinion, previously expressed, that the camera in question is an infringement not only of our patent No. 4102, 1885, but also of our No. 15,657, 1891. We have taken further advice in the matter, and are prepared to stop the sale of the camera if placed on the market. If you are willing to do so, it would save time and trouble. If you give us the name of the manufacturer, &c., we will communicate direct with him." That was a letter written deliberately for the purpose of deterring the Stereoscopic Company from completing the proposed agreement with the plaintiffs for them to put upon the market the plaintiffs' camera. It was intended for that purpose, and it was intended to deter them. It was a statement—a *bonâ fide* and honest statement, no doubt; but it was a statement that they were prepared to stop the sale of the camera, and that, of course, means if it was placed on the market by you or by anybody else. Then, instead of furnishing the name of the plaintiffs, the Stereoscopic Company themselves write to the plaintiffs by their solicitors: "The London Stereoscopic Company have consulted us with reference to the proposals for a license under your patent for improvements in cameras. We have also before us the correspondence which has passed between you and our clients." Then it explains the circumstances under which they laid it before the defendants, and they sent to the plaintiff a copy of the letter they received from the defendants, with these words in addition: "Under these circumstances it is absolutely impossible for our clients to continue any negotiations for an agreement. However useful your invention may be, they cannot submit themselves to the risk of a lawsuit. We are, therefore, instructed to inform you that our clients decline to continue the negotiations, at the same time desiring us to express their regret that both you and they should have been put to any inconvenience in the matter. In one of your letters you state that you are prepared to dispute with Messrs. Shew the point. Do you wish us to give them your name in the matter? We shall be glad to hear from you on this point." Then the next letter is on the 20th. The plaintiffs write to the defendants, having seen their letter to the Stereoscopic Company, having a copy of it before them, in which they advised the Stereoscopic Company that if the Stereoscopic Company agree with the plaintiffs, the defendants would bring an action against them, the plaintiff wrote direct to the defendants: "We are informed from the letter which you sent to the London Stereoscopic Company that you intend to dispute our right to make our patent hand camera, of which they showed you a sample. We may say we have taken competent advice from more than one eminent authority, and we are fully prepared to defend any action that you may bring. The only probable result will be the quashing of your own patent through defective specification; in any case we are advised that our camera is clear. We are sorry to have to come to litigation with you, but we are so sure of our ground that we cannot for a moment entertain the idea of withdrawing our camera from the market. We have already a number of them in hand, and these will be on the market directly. We shall be glad to hear from you what steps you propose taking in the matter." Now, the plaintiffs write that, and I must assume as against them that the statements in it were true, as the defendants would have a right to assume. Then the Stereoscopic Company writes to the defendants: "We regret our inability to send you the model of Mr. Skinner's camera, as the matter being at an end between them and us, we have considered it best to send them the models, so that they may remit them to you or not, as they deem best." Then, on the 23rd, the defendants write to the plaintiffs: "In reply to yours of the 20th inst., we can only confirm ours of the 18th inst. to the London Stereoscopic Company that we consider the camera in question an infringement of our patent, No. 4102, 1885, and 5655, 1891, and are prepared to take action to stop the sale. In order that we may go further into the matter before loss of time is incurred, if you would send us a camera, and give us the number

of the patent, it would be an aid to our further investigation of the matter, saving unnecessary delay." Then the plaintiffs' solicitors write on the 2nd of March, and then again on the 8th: "Mr. Skinner has consulted us as to the correspondence which has passed between you as to the alleged infringement by our client of your patent rights. Our client is satisfied that his invention is patentable, and, acting on our advice, he will at once file a complete specification, and leave you to contest the question. We shall be obliged by your informing us on what grounds you consider our clients' invention is an infringement of your patent. Mr. Skinner will also at once proceed to sell the camera which he has invented, and a stock of which he has manufactured." That seems, from the subsequent letter, not to be correct, but of course the defendant had a right to believe that it was correct, and the plaintiff could not be heard to say to him that it was not. I suppose the real explanation is that, although they might not have been finished, that they were nearly finished.

Mr. Everitt: A large number were in course of manufacture, but we stayed our hand in consequence of this.

Mr. Justice North: Then on the 9th the defendants asked for a camera, and on the 11th the plaintiffs' solicitors replied, referring to their own patent of 1885. I need not refer to that part of the letter. Then they say, "We give you notice that we shall issue a writ for injunction and damages on Tuesday morning unless an arrangement is come to for satisfactorily compensating our clients for the damage they have sustained, and unless we obtain from you an undertaking that you will withdraw opposition to the patenting of our clients' invention, and also withdraw your threatened legal proceedings and right to interfere with the manufacture and sale of our clients' cameras." Of course, the defendants were not bound to give such an undertaking as that, but the result was that the letter of 11th of March stayed all proceedings for a couple of months. But on the 16th of May the plaintiffs issued their writ for an injunction to restrain the threats under section thirty-two.

Mr. Everitt: Has your lordship got a copy of the letter of the 16th, in which they say they will accept service of our proceedings?

Mr. Justice North: Yes. Then the matter stands thus. Down to May no proceedings had been taken by the defendants, and the defendants do not ask, and the order I make will have a statement to this effect, that the defendants did not ask that the motion should stand over in order to enable them to bring an action under the proviso at the end of the thirty-second section, and it will also state that both parties, the plaintiffs and the defendants, ask me to treat this as the trial of the action, and to give such relief as the plaintiff is entitled to on the trial, and if I thought that damages could be awarded, to proceed now to direct an assessment of such damages. In my opinion there is a threat within the section having regard to the cases which have decided that such letters are threats. That being so, the result follows as a matter of course. I must grant the injunction worded in the way I have said, and I must refer it to Chambers to inquire whether the plaintiff sustained any and what damage by reason of the threats. Two points were set up particularly by the defendants. It is said that an answer to a question cannot be a threat. I do not see why not. I cannot see what difference it makes whether the threat is made in answer to a question or otherwise. It was a threat that was uttered by the defendants to the London Stereoscopic Company to deter them from dealing with the plaintiffs, and that being so, the fact that it was only given in answer to a question seems to me immaterial. I cannot see that there is any distinction between the defendants answering the question of the Stereoscopic Company from what it would have been if their own letter had been elicited by not a question put to them but by an exhibition in the windows of the Stereoscopic Company of a model of the camera in question.

Mr. Everitt: I have seen my learned friend Mr. Bousfield, and he quite agrees that we should treat this as the trial of the action. He does not ask for the case to stand over, and he submits, if your Lordship thought it right, to an inquiry as to damages.

Mr. Justice North: That has been done. I don't want any undertaking.

Mr. Everitt: Then as to the costs. I should ask your Lordship for the costs of the trial.

Mr. Justice North: Yes.

Mr. Everitt: And the costs of the inquiry, as to damages, will be reserved and dealt with.

Mr. Justice North: Yes: I always reserve the costs of an inquiry as to damages. You can have the costs down to the trial.

Mr. Everitt: If your Lordship pleases.

The plaintiff's solicitors were Messrs. Waterhouse, Winterbotham, & Harrison, of New Court, Lincoln's Inn.

Our Editorial Table.

We have received the catalogue of Mr. W. Hume, of 1, Lothian-street, Edinburgh, which embraces particulars of a large selection of photographic requirements. The catalogue of Messrs. Archer & Sons, of Liverpool, has also reached us. This will also be found useful to intending purchasers of apparatus, &c.

Photographic Enlargements.

By George Wheeler.

This work, which is published at 1*s.* by G. Wheeler & Co., Manchester, deals with the subject of enlargements in a practical and comprehensive manner. Mr. Wheeler in the preface informs us that it is free from any attempt to push some special make of paper or apparatus to the front, and to that extent is unbiassed. Indeed, we perceive, at a first glance through its 130 pages, that it is entirely free from anything of the nature of shoppiness. He divides his work into twenty-four sections, each of them treating of a definite topic, such as "Daylight and Artificial Light," "Exposure," "Developing," "Spotting and Retouching," "The Treatment of Faulty Negatives," "Rough and Smooth Paper," &c. To all who desire sound, practical information on the subject of enlarging we can recommend this manual.

"Photography" Annual, 1892.

Edited by Henry Shumey. London: Iliffe & Son, 3, St. Bride-street, E.C.

As well printed and got up as last year, this bulky annual is otherwise formed upon practically identical lines. The literary contents include, among many other articles of interest, a most useful record of the progress of photographic chemistry during 1891, by Mr. C. H. Bothamley. Mr. Albert Taylor performs a like office for Astronomical Photography, Mr. Chapman Jones for Photographic Optics, and Mr. T. Bolas for Photo-Mechanical Printing. The "selected" articles deal with practical subjects. Interspersed throughout the volume are a large number of excellent collotypes and "process" pictures, while the various sections of the work devoted to commercial catalogue purposes are fully furnished, and a mass of other useful information relating to societies, dealers, &c., is also given. The price of the annual in paper covers is 2*s.* 6*d.*

The *Idler* for July is brimful of amusing reading matter happily illustrated by some of the cleverest authors and artists of the present day.

Our Cruel Patent Laws, by a Liberal Candidate, is a reprint of letters and articles pointing out the injustice of the English patent laws.

No. 19,897.—"Photographic Films." Communicated by Eastman. Boult.

PATENTS COMPLETED.

Improvements relating to Photographic Cameras, and to Appliances for Changing Plates or Films therein.

No. 12,961. Benjamin Joseph Edwards, The Grove, Hackney, Middlesex. —*June* 4, 1892.

My invention is designed to provide in a more simple and efficient manner than heretofore, for effecting the change of position of sensitised plates, films or paper in photographic cameras, so that any desired number of the sensitised plates or surfaces can be used in succession.

My said invention comprises improved means whereby sensitive flexible films in continuous lengths may be used, the pictures being taken in succession upon a strip of the sensitised material which is wound upon rollers enclosed in a suitable box or case. I use a pair of rollers, which I prefer to make of such diameter that one complete turn thereof shall unwind from one roller a sufficient length of film for one exposure, and shall wind upon the other roller a corresponding portion of such film previously exposed. One of the said rollers is provided with suitable means whereby it may be rotated from the exterior of the box or case. Each of my rollers is fitted at the ends with rims or flanges, and, instead of making the roller to turn on small pivots or bearing surfaces as

is usually done, I make the enlarged ends or flanges of the rollers to rest in suitable bearings in which the said rollers revolve. The large bearings which I use for this purpose are divided longitudinally, and the rollers are arranged to be pressed into the lower halves thereof by a spring or other suitable device so as to create sufficient friction to give the necessary tension to the film as it is unwound from one roller and wound upon the other.

To keep the film constantly and evenly stretched I provide guide-rollers, over which the film will pass in travelling from one to the other of the main rollers. The said guide-rollers may be smaller in diameter than the main rollers, and are placed at such a distance apart as may be required to suit the width of the pictures. I arrange one or more of these guide-rollers to turn in slotted bearings, and the said rollers are held apart from each other by a spring or springs in such manner that, the films being held at each end by reason of the friction on the ends of the main rollers, the portion of the film which is in position for exposure will be kept tightly stretched by the outward pressure of the guide-roller or guide-rollers actuated by the spring or springs.

On the rim or flange of one or both of the main rollers I provide a projection or, preferably, a depression or recess, at one portion of the circumference, so that, when the roller has made one complete turn, it will actuate or permit the action of a spring or lever provided with a point or marker, which, by means of the said spring or lever, is pressed against the film at the end of each revolution of the roller. The mark, line, or dot which is thus produced, serves to indicate the line of division between the separate exposures, and shows where the film is to be cut previous to development. I sometimes connect the said marker with the shutter or with the mechanism which actuates the same, so that the film will be marked as the shutter falls, or is operated for each exposure, or as it is reset after each exposure.

To protect the film from the action of light before and after exposure, I provide each of the rollers, upon which the film is wound, with an improved light-tight covering, consisting of a cylindrical tube of cardboard or other suitable material, which is fitted to turn freely upon the roller, the ends of the latter being recessed to receive the ends of the tube in such manner that no light can pass to the interior of the tube. Each tube or casing is split or cut longitudinally throughout its entire length, and the edges of the slit are covered with velvet or other suitable soft material, with which, if desired, the whole of the interior of the tube may also be lined. In use, the film is drawn through the velvet-lined slit, which is kept close and light-tight by the natural spring or elasticity of the material of which the cylinder is made, or an elastic band may be passed over each end of the tube to keep the slit closed. By these means the film, except such portion thereof as is actually in use, is effectually kept from the light. The rollers, with their casings, may be easily removed from the roll-holder, and carried as light-tight film-packages, which can be inserted and removed from the camera or roll-holder in daylight without fear of injury to the film.

My said invention further comprises improved means whereby sensitive glass plates or films cut into separate pieces may be used, and whereby such plates or films may be rapidly and conveniently changed in the camera without the use of a dark room, and without altering the focus.

For this purpose I use an improved dark slide or changing box, consisting of two or more frames or cases made to slide one within the other, and in which the plates or films are contained. The plates or films are preferably fitted with suitable sheaths or carriers, or are backed with pieces of cardboard or other suitable material, of the proper dimensions. The inner sliding case is made to contain a number of the sheaths carrying the plates or films, and one end of this case is so constructed at both the back and the front as to allow one of the sheaths at a time to pass into or out of the said case. Within the outer case I provide one or more spring catches, hooks or projections, so arranged that they will engage with the edge of one of the said sheaths and retain the said sheath in the outer case, while the sliding case, with the other sheaths therein, is drawn out. When the sliding case is drawn out to the full extent, the engaged sheath is pressed by suitable springs to the opposite side of the outer case. When the inner case is again closed or pushed home, the said sheath passes into it and takes its position on the opposite side of the bundle of sheaths or plates contained in the said inner case. In this manner a succession of plates or films can be exposed, by the simple action of drawing out and closing the sliding case which holds the said plates or films, without removing the dark slide or changing box from the camera. I provide a stop to prevent the complete withdrawal of the sliding case; and to protect the plates from the light I provide a light-tight bag or box which receives the inner case when it is drawn out. For transferring the plates or films from the front to the back of the bundle thereof, I prefer to use two sets of springs adapted to act upon opposite edges of the sheath, and each of which comprises two springs so combined that they will at all times exert an approximately uniform pressure upon the sheath. Both sides of the outer case are provided with sliding light-tight shutters, one of which is so arranged that, when all the plates or films contained in the dark slide or changing box have been exposed, the said shutter may be withdrawn and the sheaths carrying the exposed plates be allowed to drop into an empty case or reservoir, which is also fitted with a sliding lid, and is so constructed that it can be attached to the changing box, and the plates or films can be transferred to it therefrom without exposure to light. The changing box is then replenished from a similar reservoir or case containing unexposed plates or films. These cases or reservoirs are made interchangeable. It is evident, therefore, that any desired number of the plates or films can be used without having to use a dark room for effecting the required changes.

The back of the sliding case is preferably provided with a sliding plate and with suitable catches to engage therewith, so that, when the sliding case is drawn out to shift an exposed plate from the front to the back thereof, the said sliding plate will be drawn out with it. The said sliding plate is so arranged that it will act as a spring to push the sheaths to the front of the sliding case and also hold the plates in the inner case when it is withdrawn. When the sheaths and plates are to be inserted in, or removed from, the dark slide or changing box, the aforesaid catches are disengaged and the sliding spring plate is drawn out without the sliding case.

I find it advantageous to arrange in the outer case a brush formed of velvet or similar material, which will effectually clean the plate or film as the sliding case is pushed inward.

I sometimes so arrange the cases that the inner case will remain stationary and the outer case will be moved to effect the changing of the plates.

My improved dark-slide or changing-box and my improved roll-holder may be made of the same external dimensions, so as to fit and be interchangeable in the same camera, in order that the operator may use either at will. They may, moreover, be fitted to any ordinary camera, which need not be of special construction.

To register the number of exposures as made, I sometimes provide a counter or index, which may be in the form of a figured disc attached to a ratchet wheel, which is moved forward automatically one notch or tooth as each fresh portion of the film is unwound, or each time the plates or films are changed Or I may employ any other suitable registering device.

Meetings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 30.—Annual General Meeting. Mr. J. Traill Taylor (Trustee) in the chair.

The HON. SECRETARY read the annual report as follows:—

TENTH ANNUAL REPORT OF THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

In presenting the tenth annual report, the Committee wish to congratulate the members on the work of the past year. There have been large attendances, and many valuable discussions have taken place, arising out of lectures given and papers read by members and other gentlemen of distinction in the photographic world, amongst others being: *Photographic Perspective*, Mr. W. E. Debenham, and one on same subject by Mr. P. Everett; *Isochromatic Photography*, Mr. B. J. Edwards; *The Lantern Microscope*, Mr. T. E. Freshwater; *A Perfect Emulsion by a New Process*, Mr. A. L. Henderson; *Some Recent Exhibitions*, Mr. P. H. Newman; *The Exaggerated Perspective of Wide-angle Lenses*, Mr. P. Everitt; *Gas Bottles and their Safety*, Mr. F. A. Bridge; *Isochromatic Plates*, Mr. John Howson; *Enlarging Lanterns*, Mr. J. Traill Taylor; *Wet Collodion*, Mr. W. E. Debenham; *Continental Photographic Institutions and their Influences*, Mr. W. H. Harrison; *Demonstration of Photography on Wood*, Mr. W. J. Rawlings; *Collodio-bromide Emulsion*, Mr. A. Mackie; *Wet Collodion*, Mr. Joseph Barker; *The Photographic Study of Clouds and Lightning*, Mr. A. W. Clayden; *The Tele-photographic Lens*, Mr. T. R. Dallmeyer; *Some Prime Factors in Exposing*, Mr. Howard Farmer.

A Drawing-room Entertainment, lantern and musical, was given on February 18 in St. George's Hall, Champion Hotel, by members and friends, to a large audience.

The Lantern Evenings, under the superintendence of Messrs. T. E. Freshwater and G. W. Atkins, have been fully appreciated.

Fortnightly outings have been arranged for the present season.

The library has had many additions, and the work of binding, &c., is being vigorously pushed forward by the librarian, Mr. F. W. Pask.

A contribution of 2l. 17s. 6d., collected from various members by Mr. A. Haddon, was sent to the Maddox Testimonial Fund.

The Association, with the view of assisting the Photographic Society of Great Britain in its efforts to improve the position of the newer societies, became affiliated to that Society, Messrs. P. Everett and F. W. Pask being appointed delegates to represent the Association.

Fifty-four new members have been elected during the year, and there have been six resignations.

Lastly, the Committee recommends that members should still continue their efforts to increase their numbers, the work done by the Association being acknowledged by the highest authorities to be second to none in this country, and the Committee would also take this opportunity of reminding the members that the series of lectures, as proposed by Mr. A. Haddon, our curator, will be commenced in the autumn, and will be delivered by gentlemen of high eminence in photographic circles. When complete, the lectures and discussions thereon will be published, and it is expected that the volume so formed will prove to be the most complete *résumé* up to date of photographic procedure.

Financially, the position of the Association is highly satisfactory, all liabilities are settled, and there is a substantial balance in hand largely in increase of that of the last financial year.

Mr. WILLIAM BEDFORD, in moving the adoption of the report, thought they might congratulate themselves upon it. He spoke, perhaps, with as little bias as anybody, being a member of several metropolitan photographic societies, and having, he was sorry to say, very little to do with the prosperity of the Association; in fact, not so much as he wished to have. But, although he did not attend very often, he was pleased to see by the reports in the journals the good the Association was doing. He thought they might congratulate them-

selves on being one of the most useful photographic societies, and, although it was a secondary matter, upon their financial success.

Mr. W. P. DANDO seconded.

The CHAIRMAN observed that the Society was one that all the world looked to for information as to advances in photography.

Thanks to the retiring officers and committee were voted, Mr. R. P. Drage, the hon. secretary, being specially singled out for a warm compliment in recognition of his services as Hon. Secretary and Treasurer during the past year.

The election of officers for the ensuing twelve months resulted as follows:—*Trustees:* Messrs. J. Traill Taylor and J. B. B. Wellington.—*Committee:* Messrs. G. W. Atkins, H. D. Atkinson, Thomas Bedding, J. Weir Brown, C. H. Cooke, P. Everett, T. E. Freshwater, J. S. Teape.—*Curator:* A. Haddon.—*Librarian:* F. W. Pask.—*Hon. Secretary and Treasurer:* R. P. Drage, 95, Blenheim-crescent, W.

A large gift of photographic literature from Mrs. Corelli Bere, per Mr. H. E. Davis, was acknowledged, and the donor thanked.

Votes of condolence with Mr. A. Cowan, in the death of his daughter, and with Mr. George Shadbolt, in the terrible balloon accident to his son, Mr. C. V. Shadbolt, were passed.

THE NEW EASTMAN GELATINO-CHLORIDE PAPER.

Mr. H. M. SMITH exhibited prints produced on the new Eastman gelatino-chloride paper. He said that the ordinary sulphocyanide toning bath was not recommended for this paper, it having been found, by a series of experiments, that it was not the best, inasmuch as it had a bad effect on the gelatine, and made it very soft, so that it required exceeding care in handling.

Mr. W. E. DEBENHAM considered sulphocyanide toning the best in use, as it deposited so much gold that he believed the prints were more permanent than those toned in alkaline toning baths.

Mr. BROMLEY SMITH showed prints on the new Eastman paper toned with sulphocyanide. The prints had been alumned. Why did the Ilford Company condemn the combined bath and the Eastman Company recommend it?

Mr. Rapson also showed prints toned in ordinary lime and acetate baths.

Mr. G. W. ATKINS asked if Mr. H. M. Smith had found any difficulty in stripping the prints from glass which had been treated with French chalk.

Mr. H. M. SMITH had found talc fail, but not wax. If the latter were used, stripping was far more easy and certain.

Mr. DEBENHAM found that success with talc depended upon its having been well rubbed into the glass.

Mr. J. S. TEAPE said that in connexion with the waxing of glass the prints should always be well alumned. He had never failed with talc if it had been well rubbed in.

Mr. W. P. DANDO, in reference to the Eastman Company's instructions to mix the combined bath and decant off the clear liquid, said that he had mixed the bath, and after it had stood four or five days there were only about two ounces of clear liquid. Was the precipitate waste?

Mr. A. HADDON pointed out that the addition of carbonate of soda and alum to a solution of hypo threw down alumina, and asked why sulphate of soda could not be added directly?

Mr. H. M. SMITH said that the Eastman Company had been experimenting with that object, and, after a few remarks from Mr. BOLAS as to the effect of sulphate of soda on gelatine, it having been employed in carbon printing, gave the following formulæ:—

COMBINED TONING AND FIXING BATH FOR EASTMAN CHLORIDE PAPER.

No. 1.

Hypo	20 ounces.
Alum	5 ,,
Soda sulphate	10 ,,
Potash sulphate	2 ,,
Water	160 ,,

No. 2.

Gold chloride	15 grains.
Lead acetate	64 ,,
Water	8 ounces.

For use, eight ounces of No. 1 solution; one ounce of No. 2.

He observed that a red precipitate was thrown down in the gold solution, but, if shaken before addition to the hypo, it would be redissolved.

Formula for Blue Tones.

No. 1.

Borax	600 grains.
Water	160 ounces.

No. 2.

Gold chloride	15 grains.
Water	15 ounces.

For use, eight ounces of No. 1; half ounce of No. 2. The solutions must be kept separate.

The meeting adjourned after passing a vote of thanks to the chairman.

Harlesden and Willesden Photographic Society.—July 5, Mr. J. Naylor in the chair.—Mr. NAYLOR gave a demonstration of the *New Cold-bath Platinotype Process.* After a short *résumé* of the history and chemical theory of the process, he proceeded to show the superiority of the new process over the older ones. The printing, he explained, required to be carried on until the image was more visible than with the old process. The members then adjourned to his palatial dark room, when a practical demonstration of the development took place. The members were much interested in the manner of development, and the methods shown of saving an over-exposed print, or, by the addition of glycerine to the developer, over-developing certain portions stronger in order to gain greater contrasts when required. Referring to the methods of obtaining sepia tones with the aid of uranium and other metals, Mr. Naylor reported a discovery of his own, which he practically demonstrated for obtaining sepia and other warm tones by the addition of a small quantity of bromide of potassium to the developer.

Leytonstone Camera Club.—June 27, Annual General Meeting. The President (Dr. W. Pickett Turner) in the chair.—The statement and balance-sheet of the hon. secretaries accounted for sixty-eight members, and showed a balance of cash in the hands of the Hon. Treasurer. The election of officers was then proceeded with for the ensuing year ending 30th June, 1893, the directorate being constituted as follows:—*President:* Dr. W. Pickett Turner.—*Curator:* Mr. Herbert Summers.—*Caterer:* Mr. Simpson Turner.—*Treasurer:* Mr. Tom Symons.—*Hon. Secretaries:* Mr. Robert Overton, and Mr. Albert E. Bailey, Rose Bank, South West Road, Leytonstone (*vice* Mr. T. F. Sanderson, who did not stand for re-election).—*Council* (in addition to these gentlemen by virtue of their office) to consist of Messrs. F. W. Wates, A. P. Wire, T. F. Sanderson, A. T. Cuffley, D. G. Riddick, A. Newton, and Mr. Reinhold Thiele. Special reference was made by the Chairman to the invaluable services of Mr. T. F. Sanderson as joint Hon. Secretary. Their only consolation in his loss was that in his successor, Mr. A. E. Bailey, they had an excellent officer, a gentleman who would bring to bear upon his duties all the tact, experience, and practical knowledge which every member of the club knew him to possess. Active preparations are being made to make the first annual public exhibition of the club in October next "a big thing," an ambition which appears likely to be realised.

Birmingham Photographic Society.—June 23, Mr. George Smith in the chair.—Mr. H. V. Cox, Messrs. George Houghton & Son's representative, exhibited the "Shuttle" hand camera. A new and very cheap hand camera, manufactured by Messrs. Lewis & Company, Limited, was shown by Mr. W. S. Horton. The Eastman Photographic Materials Company, Limited, sent a number of sample packets of their new gelatino-chloride printing-out paper, which were distributed amongst the members present. Mr. EDWIN UNDERWOOD gave a short but exceedingly interesting paper on *Actinometers and their Use.* Mr. Underwood, in the course of his remarks, said that exposure tables were utterly inadequate as a guide to possible states of the weather, as it was a matter of individual notion as to what constituted dull, very dull, &c. The preparation of the bromide paper for use in the actinometer was explained. As to the necessity of an actinometer as an aid to the photographer, Mr. Underwood read a number of "tests" from his exposure book, a couple of which will suffice as examples. On November 2, 1891, at half past twelve, it took five seconds to secure the desired tint, while at a quarter past one it took four seconds. Again, on April 8, 1892, at twelve o'clock, it took twelve seconds to secure the tint, and at one o'clock it took twenty seconds. Mr. Underwood also explained the method of establishing a ratio between the plate and actinometer, and the method of calculating the exposure, &c.

South Manchester Photographic Society.—June 27, Mr. W. I. Chadwick in the chair.—Exhibits of holiday work were brought by Messrs. Bowden, Limull, Wood, and others. Questions were asked and replied to as regards toning, &c., of the exhibits. Mr. M. W. THOMPSTONE (Hon. Secretary) read a short paper on the *Platinum Process of Printing*, and gave a practical demonstration of the new platinotype papers, in the course of which he showed that prints could be developed by going over them with a brush charged with the potassium oxalate solution, or by floating or immersing them in the usual way. Over a dozen pictures were thus produced, which were to be preserved in the Society's technical folio. Mr. Thompstone said: "The first who really appears to have endeavoured to obtain a paper printing process by the means of platinum salts seems to be Robert Hunt, but as he was unable to obtain a workable one it was allowed to drop till the year 1874, when Willis succeeded in producing the first platinum printing process that could be relied on; and which, with very slight alteration, is the hot-bath process of the present day. Willis's process is, undoubtedly, a toning one, in so much that platinum replaces iron in the same manner as gold replaces silver in the albumenised and gelatino-chloride papers. That ferric were altered to ferrous salts by the action of light was known early on in photography, for Sir John Herschell prepared paper by means of the iron salts, and replaced them after printing with gold. Willis further improved it by substituting platinum for gold, and in discovering that a solution of potassium oxalate caused a precipitate, also the advantage of platinous over the platinic salts. The paper is first coated with a mixture composed of ferric oxalate and platinous chloride, but after it has been exposed to light we have present both ferric and ferrous salts in union with the platinum one, but not in a chemical state. The ferrous salt has only the power of reducing the platinum in the presence of potassium oxalate, but the ferric possesses no such power when so treated, so the following reaction takes place: When the print is immersed in the potassium oxalate the ferrous oxalate formed dissolves, and, in so doing, throws down the platinum in a metallic state in proportion as it has been acted on by light when exposed under the negative; but where the light has not been able to penetrate the ferric salts remains unaltered, and no reduction of the platinum takes place. The next thing is to remove the ferric salt, which is done by immersing it in several changes of hydrochloric acid diluted in the proportion of one part of acid to sixty parts of water. In the cold-bath process the platinum is added to the developer instead of being contained in the paper as in the hot bath. Recently, the Platinotype Company have introduced a new paper similar to the hot bath, but the developer is used cold. This is the process I intend showing you to-night. The paper having been exposed in the ordinary way till the details can be distinguished, it is placed in the developer, viz., one pound of potassium oxalate to sixty ounces of water. The image soon makes its appearance, and darkens rapidly, but is quite under control. As soon as it has arrived at the required density it is placed in the first clearing bath, and left for about five minutes, then in a second and third till there is no trace of yellowness in the last bath, washed for about half an hour, dried, and mounted in the ordinary way. I find that I get better results with a thin but vigorous negative than I do with denser ones, and as for the results I don't think those obtained by means of silver can compare with the platinum for their velvety softness and beauty of tone." After the demonstration several questions were replied to, and various experiences given. Mr. W. I. CHADWICK read a

paper on the *Magic Lantern* (see page 437), and exhibited a sciopticon in operation, with a transparent screen made to roll up into a very small space, and supported by a pair of portable legs. The whole of the lantern and screen could be placed on a dining-room table, exhibiting a three-feet-six-inch picture, which was considered large enough for most private-house exhibitions.

Southport Social Photographic Club.—June 29.—Mr. C. F. Depree gave a demonstration on the *Intensification and Reduction of Negatives.* The process employed for intensification was that known as Monckhoven's cyanide method, by which a mixture of silver and mercury is deposited on the image, and for reduction the demonstrator made use of the ferridcyanide solution introduced by Mr. Howard Farmer. The results in both cases were highly successful, and at the close a hearty vote of thanks was accorded to Mr. Depree.

Photographic Society of Philadelphia.—June 8, Mr. Joseph H. Burroughs (President) in the chair.—A communication from Mr. F. C. Beach, Editor of the *American Amateur Photographer*, was read, in regard to a petition for the extension of the photographic privilege at the World's Fair in Chicago in 1893. On motion of Mr. Taylor, the President was authorised to sign the petition representing the 200 active and life members of the Society. Mr. G. B. Wood exhibited a small camera which a friend of his had brought from Paris. It was of the size and shape of an opera or field glass, and carried twelve plates, size 2¾ × 1¾. The lens was of a universal focus, and was contained in one side of the camera. The other side was used as a finder, the exposure being made by an exposing shutter on the lens. He also exhibited a very ingenious dark lantern for use when travelling. It contained a reservoir for stearine, so arranged that when the lamp was lighted the heat melted the stearine, which then down to the wick. The lantern was small and compact, and could be readily packed for travelling. Mr. Jennings exhibited a series of lantern and stereoscopic slides of lightning flashes. The stereoscopic pictures, he claimed, were the first ever made of the heavens' electrical discharges, and the stereoscopic effect was decidedly interesting. In one case the sensitive plate had caught the mystical thunderbolt, from which radiated, in various directions, numerous tongues of flame. The theory of the exhibitor was that thunderbolts were formed by a collision of flashes and a consequent scattering of the discharge into a number of points or balls of flame, which travelled onward into space on their own account. In another view the stereoscope revealed the fact that a discharge apparently zig-zag in its direction was really spiral in its course. Mr. Browne submitted two negatives for inspection, one of which, a flashlight picture, was disfigured by a wavy ribbon of light across the centre. The other was dotted with small circular spots of white glass. The latter he believed to be due to the use of a rose nozzle in washing, a wearing away by the continued action of water; but the former he was utterly at a loss to account for. Mr. Wood stated that he noticed the other day, on examining certain negatives taken seven or eight years ago, that the film was leaving the plate—coming off in great flakes. The plates were not frilled when developed, and he thought, perhaps, the alum bath rendered the film brittle, and gave it a tendency to leave the plate. Mr. G. M. Taylor said he knew of an instance where the film had left the celluloid altogether—had peeled off in one piece. Mr. Young exhibited negatives made by the new Zeiss Anastigmat lens manufactured by the Bausch & Lomb Company. The lens was 4 × 5, but Mr. Young tried it on a 6½ × 8½ plate, with full opening, and it covered the plate well to the margin. The definition, depth of focus, and rapidity were remarkable. Mr. Pancoast showed a panoramic photograph of the city of Waterbury, Conn., which he had taken by means of an adjustable tripod top of his own manufacture. Four 8 × 10 plates were used, and the pivotal top he had carefully subdivided into four positions, embracing in all 101 degrees. He had a supplementary arrangement with five positions, which would take in 124 degrees. The picture exhibited showed great uniformity, and the continuity was admirable.

Correspondence.

"TALBOT ARCHER" AND THE CONVENTION.

To the Editor.

Sir,—"Cosmos" and my kind friend "Brum" must indeed think me a green hand if they fancy I am to be "drawn" by their anonymous and personal remarks. We have all heard of "Satan reproving sin," and their communications are indeed a case in point. Some time back, similar letters attacking me appeared in a photographic periodical, and when the editor wrote to the address given it was found to be a void house in this city. But, under any circumstances, I should not think of committing the gross breach of press etiquette into which they would speciously try to lead me. I shall take no notice whatever of any further communications upon the subject.—I am, yours, &c.,

Birmingham, July 4, 1892. W. J. Harrison.

[In bringing this controversy to a close, we cannot refrain from observing that, as we understand press etiquette, Mr. Harrison is in no sense precluded from denying such charges as those which "Cosmos" prefers against him.—Ed.]

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editor.

Sir,—Our attention has been called to a letter in your issue of 24th ultimo from Messrs. B. J. Edwards & Co. on above subject, and having acted as agents for Dr. Vogel in connexion with his British patent and the opposition of Messrs. Edwards thereto, in the interest of our client we cannot allow the statements in said letter to remain uncontradicted.

We shall therefore be obliged if you will permit us to state that so far from its being correct that such patent was "successfully opposed" by Messrs. Edwards, the fact that such patent was granted is clear proof that the opposition to such grant failed, the Comptroller in his decision stating that in his opinion 'the process of Dr. Vogel differs materially from that of Abel'—that is, the patent on which Messrs. Edwards relied to prevent the grant of Dr. Vogel's patent. It is true that a reference clause was inserted in the specification, but in stating this Messrs. Edwards omit to point out that before the opposition was heard Dr. Vogel offered to insert in his specification a clause with a specific reference to the Abel patent, but that Messrs. Edwards refused to agree to this (although the original suggestion that such a clause should be inserted came from the patent agent acting for them in the matter); while in his decision the Comptroller does not consider it necessary that the reference clause should make such specific reference to said patent, and in other ways makes the reference clause much less comprehensive than the one Dr. Vogel was prepared to agree to without any compulsion. We therefore entirely fail to understand how Messrs. Edwards can consistently maintain that their opposition was in any sense successful.

With regard to the claims, it is absolutely incorrect that "by order of the Comptroller, Dr. Vogel's principal claims were struck out." The reduction of the number of claims was *not* by order of the Comptroller, but on the suggestion of Dr. Vogel's own counsel, as he thought that those retained fully covered the invention, the others (so far from being the *principal* ones) being superfluous); and as we agreed with this view we recommended Dr. Vogel to adopt this suggestion, which he did. The Comptroller in his decision leaves the matter of the omission or retention of any of the claims entirely to Dr. Vogel's discretion, his words being, "Any or either of the claims numbered 2, 3, 4, and 5, may be struck out, *as proposed by the applicants' counsel at the hearing.*"

With the exception of the insertion of the reference clause stated, and the omission of such claims as were considered superfluous (and which it was left to Dr. Vogel to omit or not as he chose), the specification originally filed was in no way altered.

We totally deny that the legal effect of the reference clause inserted is "that the process, if used at all in this country, could only be so used by licence under the Tailfer (Abel) patent," as it in no way refers to such patent; and even if it did, it would not prevent Dr. Vogel from contesting the validity thereof, or maintaining that his patent does not infringe same in any way.—We are, yours, &c., Allison Bros.

52 *Chancery-lane, London, W.C., July* 1, 1892.

To the Editor.

Sir,—In your valuable Journal (June 24, p. 414), Mr. Edwards asserts that "the system of 'optically sensitising' by means of dyes is well known as Dr. Vogel's, and should not be confused with the Tailfer process of chemical sensitising," which, if there is any meaning in it, shows that Mr. Edwards does not know what an optical sensitiser is.

I call an optical sensitiser such a one which sensitises bromide or chloride of silver only for those spectrum rays which it absorbs. That action is one proper to both eosine and erythrosine; hence, in my meaning of the word, *both* are *optical sensitisers.*

A chemical sensitiser, on the other hand, would be one that combines with iodine or bromine liberated by exposing iodide or bromide of silver to light. Eosine and erythrosine do not do that; they are therefore not chemical sensitisers in my application of the word.

Now, I can assure Mr. Edwards that I am as anxious as he is that my system of combining, in a definite form, the dye with the soluble silver bath should not be confused with his (Tailfer's) plan of "*chemical sensitising,*" *as he calls it,* in which "*only so much remains in the film as is combined with the silver bromide.*

It may be remarked that an attempt was made to patent the Tailfer process also in Germany, but, as it is the duty of the German Imperial Patent Office to examine patent applications and claims beforehand as to their novelty, the said patent was refused by the German Imperial Patent Office.

Mr. Edwards opposed my English patent for the application of "Eoside of Silver," not, as he says, successfully, but *unsuccessfully*, for the patent was granted with *slight* modification of the claim, and the *principal* claim —that of the silver eoside—*was granted, not struck out*, as Mr. Edwards asserts.

He proceeds to say "that the process was no improvement, and of no commercial value" on account of the want of keeping qualities of the plates. This statement is on a par with his other assertions. Apart from England the plates are sold largely in Germany, Italy, and America, and the sale is continually increasing. That the early plates, made four or five years ago, may sometimes have been deficient in keeping quality has nothing to do with the *principle* on which they are made sensitive to the yellow-red rays of the spectrum, but with the want of sufficient experience on the part of the plate-makers. Their keeping quality is now everything that could be desired, though the process by which they are made differs in every essential point from that of the Tailfer patent. The manner in which Mr. Edwards derides the value of my process needs no comment, as it only shows his own ignorance of these matters.—I am, yours, &c., Dr. H. W. Vogel.

Berlin, June 30, 1892.

To the EDITOR.

SIR,—It is far from my wish or intention to enter on a controversy on the above subject, but I cannot allow Mr. Edwards' letter, charging me with inaccuracies, and which I cannot for a moment admit, to pass unanswered. I may at once state that I am quite willing to stand by every word in my paper, which has been written neither hastily nor without sufficient data at my command.

Regarding my mentioning Mr. Clayton's name, I had no intention of making out a complete list of those who have helped to make orthochromatic photography what it is to-day, or I should not have left out such names as Captain Abney, Mr. Bothamley, and many others. However, Mr. Edwards' remarks amount to the veriest quibble. To the outside world Mr. Clayton is just as much the so-called real inventor as Mr. Tailfer; and, moreover, in other ways, Mr. Clayton is at least as conspicuous as Mr. Tailfer. But this is absolutely unimportant, and outside the question.

We are not all obliged to agree with Colonel Waterhouse that to Mr. Tailfer "alone is due the credit of the successful application of the colour-sensitising properties of eosine to the gelatino-bromide process," and, even if we did, it would have no effect on the question of patent value.

With reference to my "incomplete description of the Tailfer process," I have given it as full as possible. There is no description of *modus operandi*, as any one can see for himself who will take the trouble to read Patent No. 101, 1883, and certainly no one could make plates commercially (this has been tried) with only the specification information.

That the Tailfer plates were not dyed, is an incorrect statement of Mr. Edwards'. I have had many boxes of Tailfer plates, and they were very red in colour. With regard to the plates manufactured by Messrs. Edwards & Co., it is quite another question—a very small amount of dye *is* present, but that dye is present combined with silver, as recommended in Professor Vogel's patent. I have already given my views *re* "optical" and "chemical" sensitising in my paper, so will not take up your space with that subject. They are, however, diametrically opposed to those of Mr. Edwards', but I may mention that they are quite in accord with those of Captain Abney and others. Professor Vogel's patent was *not* successfully opposed by Mr. Edwards—the patent was allowed, after adding a disclaimer, which in no way affected the validity of the patent, and, if sufficient technical and scientific knowledge had been at hand even this disclaimer would probably have been superfluous. The true reason why Dr. Vogel allowed his patent to lapse, was, I suppose, because no one had either sufficient enterprise or ability to work it in this country. And it is not true that the process has no commercial value, for plates are made in large quantities in Germany and elsewhere by this method (Dr. Vogel's), and all, or nearly all, orthochromatised plates I have come across contain silver associated with the dye. Plenty of plates manufactured by Vogel's process have, I understand, been sold in England since the granting of the patent. In connexion with the whole matter, Professor Eder is the greatest authority on the subject, and his expressed opinion is entirely in favour of the Vogel method.

With reference to Messrs. Lumière working under a licence from Tailfer, I have had some further correspondence from M. Vidal, which will tend to show by what kind of means the poor patent has to be propped up. My statement in my paper was also from M. Vidal's letter; I give his own words: "Le brevet de MM. Clayton & Tailfer n'est exploité que par le titulaire Attout-Tailfer, et encore très peu, ses produits étant de valeur inférieure. Les plaques que l'on préfère sont celles que fabrique la maison Lumière de Lyon; elles sont préparées par un procédé tout différent." In a more recent letter M. Vidal says: "Quant au Lumière, voici ce qui s'est passé. Cette maison produisait des plaques orthochromatiques. M. Tailfer les a menacé d'un procès. Voyant les menaces sans effet M. Tailfer a fait offrir à MM. Lumière de leur accorder *gratuitement* une licence. Ces messieurs voyant qu'ils éviteraient aussi les ennuis du procès dont on les menaçait—bien qu'à tort—ont consenti à *acheter* gratuitement la licence en question, à la seule condition de mettre sur les boîtes les mots '*avec l'autorisation de M. Tailfer*,' ce qu'ils n'ont fait que quelques fois. M. Tailfer a voulu user de sa victoire en entraînant la maison Monckhoven à lui acheter une licence; et il lui a écrit qu'il lui donnerait pour rien, tandis que MM. Lumière lui avaient payé 30,000 francs. J'ai montré à la maison Monckhoven la lettre de Lumière me déclarant ce qui s'était passé: 'Rien payé, pas un centime,' dit cette lettre." And much more information, not particularly edifying to those concerned, which I would prefer to withhold.

Apologising for taking up so much of your space,—I am, yours, &c.,

July 4, 1892. J. J. ACWORTH, Ph.D., F.I.C., F.C.S.

HELIOCHROMY.

To the EDITOR.

SIR,—In reply to Mr. Ives' remarks, page 430, I will begin by quoting his own words: "I regret that I am obliged to occupy your valuable space with replies to statements which ought never to have been made." But so long as Mr. Ives continues to publish wrong assertions against me, I am obliged to answer him. He asserts that an "identical statement" (like that he communicated to the Franklin Institute over his claims) "was submitted to Dr. Vogel for criticism." I answer, *I have never received such a statement.*

Mr. Ives says further, "Dr. Vogel also certainly knows that Du Hauron never gave my (Ives') chlorophyll process up in favour of Dr. Vogel's eosine process." In reply to that, I may mention that I have never asserted that Ducos du Hauron had used *Ives'* process or *my* eosine process, both published several years *after* Du Hauron's paper.

Mr. Ives says further, that my "idea cannot be carried out in accordance with the facts which support the Young-Helmholtz theory," &c. I answer, My idea is *already carried out* and worked out in practice in Berlin. Specimens of my process were again exhibited here three weeks ago, and have received the praise of the most eminent painters and scientists of Germany, and of the first art critics of the German newspapers. Even Dr. Von Helmholtz himself has visited this exhibition, and declared that the results *are in accordance with his theories! Verb. sap.* Perhaps Mr. Ives only knows those parts of Helmholtz's researches which are related to Young's, but not Helmholtz's many other independent papers on over-colour vision.

Mr. Ives says further, "Dr. Vogel was in error when he says he acknowledged the 'heliochromoscope' on page 318." I maintain my assertion as true. Every reader of your valuable JOURNAL may convince himself of the correctness of my words. More than that, I have also acknowledged the heliochromoscope in the *Standard*, in an article Mr. Ives has certainly read. I allow Mr. Ives the honour of employing the old Ducos du Hauron principle first for making coloured lantern slides by projection.

But I am sorry to say that I must now qualify my acknowledgment, since Mr. L. Vidal, of Paris, has published in *Anthony's Bulletin*, p. 297, the following lines:—"We consider it as a duty to remind him (Ives) that a description of the principle of the apparatus of this kind (heliochromoscope) appears in a paper published in 1869 by C. Cros."—I am, yours, &c.,

DR. H. W. VOGEL.

Berlin, July 4, 1892.

SPEED OF PLATES.

To the EDITOR.

SIR,—The mode of ascertaining the speed of plates proposed by Mr. Watkins in his letter of May 20, and further explained in your last issue, would be very simple indeed if it could be shown to be reliable; but, unfortunately, it will be found that development, for a certain time, will not ensure the results desired. As pointed out by Mr. Phillips, much more extended observations must be made even to obtain an approximately accurate result.

Granting that, if carefully made, a Spurge's sensitometer might give as great an accuracy of comparative illumination as the simple plan adopted by Messrs. Hurter & Driffield, I am unable to see that it would be more convenient. A number of plates could not be exposed at the same time, by which means the effect of any slight variation in the source of light may be eliminated, and a fair comparison made.

Mr. Watkins objects to the standard candle, but does not suggest anything superior, and, should he succeed in finding a better standard than the candle now used by Messrs. Hurter & Driffield, the accuracy of which is very great when their conditions respecting height of flame are strictly adhered to, it will be equally available for either method of exposing the plate.

The densities obtained still have to be dealt with, and I select the following to show that no indication of the speed of plates can be obtained by the simple comparison of the densities as proposed by Mr. Watkins. Four plates of unknown speeds were exposed at one time (1¼ to 160 candle-metre seconds), and developed together for the same length of time. The densities, when measured, were as under:—

	1.	2.	3.	4.
1¼ C. M. S.	·09	·14	·30	·16
2½ ,, ...	·33	·47	·50	·43
5 ,, ...	·68	·86	·74	·77
10 ,, ...	1·06	1·26	1·01	1·13
20 ,, ...	1·45	1·64	1·21	1·47
40 ,, ...	1·76	1·92	1·33	1·78
80 ,, ...	2·01	2·17	1·44	1·97
160 ,, ...	2·21	2·31	1·55	2·14
Inertia	1·45	1·1	·65	1·1
Actinograph speed.....	23	31	52	31
Development factor	1·25	1·3	·85	1·15

Densities of 1·45, 1·44, and 1·47, which, to the eye, appear equal, are found upon plates 1, 3, and 4, and, being due to the same exposure upon 1 and 4, the plates would, by Mr. Watkins' method, be considered of equal speed, instead of as 23 to 31.

The same density upon No. 3 was only obtained with four times the

light, and would be taken to be four times as slow as the others, whereas it is twice as rapid as No. 1.

Nos. 2 and 4 are equal in rapidity, but do not correspond in density anywhere.

It will be seen that the different development factor reached in each case prevents the estimation of speed by inspection, and is most misleading with the fastest plate. When, however, the curve is laid down upon Messrs. Hurter & Driffield's plan, the speed of the plates is at once determined with great accuracy.—I am, yours, &c., JOHN STERRY.

Redhill, July 4, 1892.

THE DARK FLASH.

To the EDITOR.

SIR,—I can corroborate Mr. Dunmore's statement in last week's BRITISH JOURNAL OF PHOTOGRAPHY *re* the above, as I saw it quite distinctly; there were, however, two flashes, one light, the other dark, and, although I saw both flashes practically at the same time, the light one seemed to be formed first, probably because it travelled quicker than the dark one. The effect took place about 10 p.m. in the north-east part of the sky, the light flash being on the northern, and the dark flash on the eastern side, the colour of this being difficult to describe other than a mixture of very dark red or purple brown, with dark grey, the background of clouds being illuminated by the light flash.—I am, yours, &c.,

Tonbridge, July 4, 1892. J. BARKER.

TONING SILVER PRINTS DURING THUNDERSTORMS.

To the EDITOR.

SIR,—Last night (Tuesday, June 28) we had one of the most terrific thunderstorms ever known in this neighbourhood.

Can you or your readers tell me if they have ever found great difficulty in toning silver prints during the time of, or immediately preceding, a severe storm? I found my prints would not tone up to the usual standard of colour on Tuesday night, and yet I used the same bath that I have used for years, and which I found answered well on Wednesday morning after the storm had passed over.

What I want to know is, Am I justified in attributing the fact that my prints refused to tone to the intensely electrical state that the atmosphere is supposed and believed to be in at such a time?

I enclose two prints with notes at the back, and you can publish this or not as you think well. If you think it of interest, I would write a short article for the ALMANAC next year.—I am, yours, &c.,

High-street, Weybridge, June 29, 1892. THOMAS GRIFFIN.

CORRECT EXPOSURE.

To the EDITOR.

SIR,—As Mr. Michael adopts my wording that "the stop has been reduced to a quarter of the area, and allows exactly the *same* amount of light to pass as before," surely it is evident that when the plate is placed at half the original distance (which fact I had by no means forgotten), where the *same* amount of light covers the *same* area of plate, the illumination must be equal.—I am, yours, &c., JOHN STERRY.

Red Hill, July 4, 1892.

To the EDITOR.

SIR,—The law relating to the intensity of illumination upon which Mr. Michael bases his argument does not apply to the case at all; it is true only of *diverging* rays, and depends entirely upon the fact that the further an object is from the source of light the fewer will be the rays that fall upon it, and not because any individual ray loses in intensity.

Now, in the case of two lenses, one double the focal length of the other, and both having the same relative stop, the number of rays of light from any unit of surface of the landscape which pass through the stops will, in the case of the longer-focus lens, be four times greater than in the case of the shorter-focus one, for the area of the stop is as four to one.

The shorter-focus lens, however, forms an image on the plate with these rays, which is only a quarter the area of the image formed by the longer-focus one; therefore in each case the number of rays of light which fall upon a given unit of surface of the plate will be equal.—I am, yours, &c., E. COLLIER GREEN.

Derby, July 6th, 1892.

THE PRICE OF SILVER.

To the EDITOR.

SIR,—On all sides it is said that silver was never known to be cheap as it is now. Why is it, sir, that photographers cannot benefit by this low state of the market? There is nothing to grumble at as to the price paid for plates, but surely there is no genuine reason why sensitised paper should remain at the price it was when silver was nearly double its present rate. If you kindly insert this in the JOURNAL, it may be that some of the makers of sensitised paper will come to the fore and enlighten the subject a little.—I am, yours, &c., A. HORTON.

Cardiff, June 29, 1892.

PRESERVATION OF SILVERED MIRRORS.

To the EDITOR.

SIR,—Mr. Ives is exactly thirty-six years too late with his suggestion. When Liebig first published the process in 1856, he suggested that the surface should be varnished. I quote from his paper as given in the *Journal de Pharmacie et de Chimie*, troisième série, tome trentième, page 74, as follows:—"Lorsque le miroir est sec, on recouvre le tain d'un vernis incolore composé d'une dissolution alcoolique de résine de Dammar; ensuite on encadre." For astronomical purposes, no one nowadays would ever dream of spoiling the surface of mirror or flat with varnish. The silver film adheres to the glass so tenaciously when properly done, that it will bear a very great amount of rubbing without coming off. Dr. Draper has stated that the thickness of the silver film is only the $\frac{1}{250000}$ of an inch. Varnish of any kind, whether celluloid or collodion, never could be put on of such extreme tenuity as to approach this, and of uniform thickness.

I have had considerable experience recently in silvering mirrors ground by myself, and I should never dream either of varnishing them or of polishing the silver film with *cotton wool* and rouge.

July 5, 1892. PROCELLA.

["Procella" is not quite correct in several points. First, Mr. Ives' suggestion of using a celluloid protection for a mirror cannot well be "exactly thirty-six years" too late, for celluloid has not yet been this time before the world, and the quotation given from Liebig speaks of dammar, not celluloid varnish. Secondly, Is "Procella" sure that Liebig was the first to publish the process in 1856? Is he unaware that the invention was really made and patented by Thos. Drayton, a London chemist, in December, 1848? Lastly, the application of the varnish was suggested, not to ensure the adhesion of the silver to the glass, but to prevent its becoming tarnished.—ED.]

INCREASE OF PLATE SENSITIVENESS BY KEEPING—TONING AND FIXING BATHS.

To the EDITOR.

SIR,—Two items in the JOURNAL of this week have arrested my attention. First, with regard to the increase of sensitiveness of dry plates by keeping, I wish to bring to your notice what has happened in my own case. In the early summer of 1890 I prepared a batch of plates by boiling with ammonia, and on trying I found them extremely slow and thin, but clean and with good detail. I put them up in the dark room, closely papered, and in empty negative boxes. They have lain there since, till last week. At that time I was in Belturbet, but my son was carrying on the business. I was quite surprised to hear from him that, being short of an Ilford half-plate, he used one of this old batch. Result, a good printing negative and exposure same as he was giving Ilford Ordinary. This is item one.

The Eastman combined toning and fixing bath.—In reading over your "Editorial Table," I was struck with the similarity of the first part of their fixing and toning bath to one for fixing, which I submitted to the Ilford people some months back, and for which I claimed that it would render the gelatine surface so hard that after enamelling water could be taken off the face of the paper without leaving a mark on the glossy surface. I believe I am amongst the oldest of emulsion paper workers, commencing with Obernetter's collodio-chloride of silver paper in 1873, and following the same maker in gelatine to the advent of the Ilford people.

Formula for fixing bath,—

Hypo. of soda	16 ounces.
Alum	16 ,,
Bicarbonate of soda	4 ,,
Water	4 quarts.

Hypo dissolved first, bicarbonate added and dissolved, and alum last. A copious white precipitate falls, which settles in twenty-four hours, when the clear part is decanted for use. Time of fixation, not less than ten nor more than fifteen minutes.—I am, yours, &c., J. PATTERSON.

Caron, Ireland, June 25, 1892.

Exchange Column.

**** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange a sweet-toned American organ, very little used, for a 15×12 or 12×10 camera, with three double slides; must be light, for outdoor photography.—Address J. E. COLE, the Studio, Holy Croft, Keighley.

Will exchange ferrotype camera, fitted with two lenses, to take four pictures on half-plate, for a few really good backgrounds, interior and exterior.—Address, J. WILLIS, Rembrandt Studio, Southend-on-Sea.

Will exchange Lancaster's gem camera, nine lenses, takes thirty-six on plate 7×5, with 1890 Gem and Victoria mounts, for half-plate or 7×5 rapid rectilinear or rapid symmetrical lens, any good maker.—Address, T. MILNTHORP, Market-place, Romsey, Hants.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

G. B. Bradshaw & Co., Altrincham.—*"We'll be late for the poll."*

John William Beanfort, Birmingham.—*Photograph of Austin Chamberlain.*

Thomas Ashby Flemons, Tonbridge.—*Photograph of the Luncheon Party at Tunbridge Vicarage, June 28, 1892.*

J. C.—Received.

R. C. PHILLIPS.—Thanks; next week.

PERPLEXED.—The print is imperfectly fixed.

C. H. M. (West Hampstead).—Received; thanks.

CHEMICUS.—By ammonic hydrate the ordinary liquor ammoniæ ·880 is generally understood.

D. AVANZO.—Hardwich's *Photographic Chemistry* (J. & A. Churchill, Burlington-street, London, W.). Price 7s. 6d.

G. SCOTT.—Under varying conditions the three kinds of plates named are, probably, equally as good for portraiture.

VALENTINE & SONS.—A cold varnish for negatives may be made by dissolving gum dammar in benzole to the consistency of cream.

SPOTS.—The mottlings on the prints are due to the action of the mountant on the mount, the enamel of which was not properly "fixed."

NONPLUSSED.—The prints were imperfectly fixed. The discolouration of the silver solution is due to the dye being abstracted from the paper.

CADMUS.—Given both forms of lens mentioned of good construction, their defining powers both for foreground and distance should be equal.

R. STURROCK.—Yes, you have been rightly informed. Glycerine applied to a print on the new platinotype paper before development acts as a restrainer.

J. WOOD.—A negative from a negative may be made by the addition of sulphourea to the developer, according to the method suggested by Colonel Waterhouse.

A. WYNCH.—I. The mountant given at page 790 of the current ALMANAC is, perhaps, as suitable as any. 2. The "permanence" of gelatino-chloride prints has not yet been called into question.

A. Z. Y.—The "peculiar marks" on the prints are due to finger or thumb marks on the paper before it is printed, or, may be, before toning.

SYDNEY A. HARDING.—There is a work on *Collotype and Photo-lithography* by Dr. Julius Schnauss, translated by Mr. E. C. Middleton. It is published by Messrs. Iliffe & Son, St. Bride-street, E.C.

SEVERAL correspondents who have forwarded us Messrs. Hamfeldt and Stahlberg's circular relating to the Helsingfors International Photographic Exchange are thanked for responding to our invitation.

PATENTEE.—Before you commit yourself to any threat against the dealer who you say is infringing your patent rights, you had better make a careful perusal of the important law case which is given in another part of the JOURNAL.

SAXON.—Considerable intensity, probably greater than that obtained by the ordinary processes of mercuric intensification, may be imparted to the negative by bleaching as usual, and "blackening" with an ordinary ferrous-oxalate developer.

E. HARVEY—Permission to photograph in the royal parks may be obtained by addressing H. W. Primrose, Esq., Office of Works, Whitehall, S.W.; and for the other parks of H. de la Hooke, Esq., London County Council, Spring Gardens, S.W.

A. STANWAY.—In the best studios on the Continent only plain backgrounds are used, or landscapes and interiors, which are artistically painted so that they are little more than suggestive. The pronounced scenic background of twenty years ago is never used now.

C. W. KINGSTOW (Glamorgan).—From the description, the paper seems to be of the right kind. But we cannot say for certain without seeing a sample. If it was supplied by a photographic chemist for the purpose required, it is no doubt the correct thing.

B. BROWNLOW.—The only way of keeping the sun out of the studio is to make the outside boards higher. Bear in mind that at this time the sun is at its highest altitude, and it is for this reason that the hoarding that effectually stopped it out a month ago, does not do so now.

S. A. (Leeds).—The best work for your purpose, although it does not deal specially with photographic chemicals, is Fresenius' *Chemical Analysis*. There are two volumes, one devoted to qualitative, and the other to quantitative analysis. The former will answer your purpose at first.

ALIC.—In our report of the last meeting of the London and Provincial Photographic Association you will find two new formulæ of the Eastman Company for their gelatino-chloride paper, the employment of either of which will obviate the precipitate of which you complain with the original formula.

F. HARRINGTON & Co. ask where a copy of the catalogue of the Munich Fine Arts Exhibition can be obtained. Any foreign bookseller would, we presume, obtain a copy to order. Or a Post Office Order for two marks, and the necessary amount for postage, addressed to the Secretary of the Exhibition, the Gaspalast, Munich, would secure a copy.

C. P. C. asks: "Who is the person to apply to for permission to photograph Tintern Abbey?"—Perhaps some reader can supply the information desired.

S. W. C.—In taking reversed negatives for photo-mechanical and other purposes for which they are required, a mirror, provided it be optically plane, will answer quite as well as the more expensive prism. But it must be borne in mind that a defective mirror, or prism, will quite destroy the quality of the most perfect lens. Therefore, whichever be used, it must be optically perfect.

F. STONEHAM.—Pizzighelli & Hubl's work on *Platinotype* (published by the Photographic Society of Great Britain, price 2s.) treats exhaustively of the earlier platinum processes. There is no book which brings the subject up to date, and your best plan, therefore, would be to consult the indices of our more recent volumes, and digest the various articles on platinotype contained therein. This, with the necessary practical experiments, should meet your purpose.

E. COOPER asks for a simple method of reducing silver prints that are over-printed.—Several methods have from time to time been suggested which, in a sense, answer; but the prints are seldom as good as those that are printed to the proper depth in the first instance. As a matter of fact those who print professionally do not consider it worth while to waste time in doctoring over-printed impressions, but simply tear them up and make fresh ones. Our advice is, follow their example and do the same. It will save time and ensure better results.

S. A. J. says: "I was apprenticed to my present employer for three years. My uncle paid a premium of one hundred and twenty-five pounds for the apprenticeship, I to receive nine, twelve, and fifteen shillings a week as salary. I have served two years of the time, and have done nothing but printing, and have never yet worked in the studio. In fact, I have been employed solely to do the work of a man whom he would have to pay three times the wages to. Can I compel my master to teach me the portrait work?"—This is a very common complaint of those who take apprentices with a premium. The uncle should consult a solicitor on the matter.

S. TREBBS writes: "I have got—or, rather, expect to get—an order to photograph a quantity of furniture to illustrate a manufacturer's catalogue. A great deal of it is inlaid wood. Some is inlaid with metal. As I have never done anything of the kind before, although I am an old photographer, can you give me any hints that will help me, I mean with regard to photographing this class of work?"—The best effects will be obtained by photographing the objects before they are polished, as then there are no reflections to contend with, and finer detail will be obtained. It is in the unpolished state—after being slightly oiled, which brings out the grains of the wood—that this class of goods is most satisfactorily photographed. If, however, the things are already polished, then they must be dealt with as they are, in which case use backed plates, and arrange the lighting so as to avoid reflection in the direction of the lens as much as possible.

COLLODION writes: "Kindly inform me of a reliable method of keeping wet plates wet for two or three hours after sensitising, so that they can be exposed after that length of time. Is there not a method of coating with a liquid of which Bass's beer is a constituent?"—There are several methods by which collodion plates may be kept moist, such as coating them with such things as honey, oxymel, glycerine, &c., but they are all more or less unsatisfactory, particularly with regard to sensibility and quality of negative, except in experienced hands. The beer, coffee, and other processes of that class are practically dry processes. It will be found far more convenient, when negatives of the wet-plate character are required, and the plate cannot be exposed as soon as prepared, to use some of those plates specially prepared for photo-mechanical work. These plates are slow, but they yield negatives that have all the characteristics of wet-plate ones.

WEST LONDON PHOTOGRAPHIC SOCIETY.—July 9, Oxted.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—July 14, Members' Open Night. 16, Outing, West Drayton.

PHOTOGRAPHIC CLUB.—July 13, *Photographing Natural History Specimens.* 20, *Photo-mechanical Processes.* Outing, Saturday next, July 9, Rickmansworth. Trains from Euston, quarter past two.

MR. ALEXANDER P. TAYLOR, late photographer, Dunfermline, died at his residence in New-row, Dunfermline, on Thursday, June 23. Mr. Taylor had suffered from indifferent health for about six months. Mr. Taylor was a native of Dunfermline. He began life as a grocer, but his knowledge of chemicals led him ultimately to give up the grocery trade and take to photography. Photography had scarcely been reduced to an art in Mr. Taylor's early days, and if the work he produced would not compare favourably with what can be had in Dunfermline to-day, it was wonderful for the times, and certainly creditable to a man who had, in the real sense of the words, been self-taught. Mr. Taylor was sixty-eight years of age.

JOURNAL OF PHOTOGRAPHY.

No. 1680. Vol. XXXIX.—JULY 15, 1892.

SOME POINTS IN MR. DAVISON'S ADDRESS TO THE CONVENTION.

The chivalrous compliment which he pays to Mr. H. P. Robinson in the opening sentences of his address, and the modest manner in which he exempts himself from following in the footsteps of his predecessors in the presidential chair in criticising scientific advances or inventions in photography during the preceding year, are in that admirable taste which we looked for in the President of the Convention. And, if Mr. Davison does not wholly confine himself to a consideration of the bearings which those new developments and discoveries have upon pictorial work in photography, he disarms the objections of those he may have disappointed by demonstrating to them by his intelligent references to recent optical improvements, to Messrs. Hurter & Driffield's labours, to the struggle for the survival of the fittest among printing surfaces, to photo-mechanical processes, and other subjects usually conceded to be the almost exclusive concern of those to whom photography is of least account as a picture-making art, that it is difficult, if not out of the question, for those who profess to pin their allegiance to photography, simply because it is capable of realising their aspirations after artistic effect, to avoid acquiring and holding a deep interest in the progress of photographic science, of which it is an undoubted obligation that they should cultivate a knowledge hardly less comprehensive than that of scientific men themselves.

Briefly it comes to this, that Mr. Davison, as the accredited spokesman of that large and growing section of photographers to whom photography appeals as an art and as an art alone, annihilates the fiction that that school can afford, or really attempts, to ignore or remain indifferent to its importance as a far-reaching progressive science. In fact, photographic science must be nearly as much at the finger ends of the artist in photography as of the photo-micrographer, the photo-astronomer, or any other investigator who joins photography to his aids to discovery.

Mr. Davison's defence of "suppression of definition," or "diffused treatment" in modern photographs, is somewhat discounted by the circumstance that it is studiously based upon almost purely personal predilections. He seems, indeed, by his declaration in favour of an individual preference in the matter of the focal treatment and tone rendering of photographs, rather to seek to avoid than to reopen or prolong the inevitable controversy as to the exact value of definition in photographic pictures. But, candidly, while complimenting Mr. Davison on his diplomacy, we cannot help remarking that, as the point is one which is of fundamental importance in the application of photography to artistic purposes, its discussion in the fullest and freest manner is highly desirable. Mr. Davison forgets that public taste has yet to decide between definition and no—or "differentiated"—definition, and we have little hesitation in conjecturing that, if the public preference is conclusively realised to be in favour of the former, the result, despite the small and temporary influence of outside critical impressionism, must lead to the relegation of non-focussed landscape and other kinds of work, to a position of artistic unimportance, if not neglect.

Mr. Davison's regret that the "broader treatment" advocated in former days has not survived is allowable enough, but, in venturing the opinion that "almost the only valuable artistic survivals from that period are in the particular broad focussing of Mrs. Cameron's powerful and original pictures," he perhaps does not exalt that lady's portrait work too high, but errs, we think, in omitting mention of the work of Robinson, Diston, Rejlander, and many others who for a long span of years were admitted to have worthily upheld photography as an exponent of the highest artistic capabilities. If, according to the President's personal leanings, their treatment was not "broad" enough, surely he does not on that score refuse to concede the artistic value of their work? The focal treatment of a landscape is apparently merely one of degree of breadth, determinable by the individual, but it seems strange that "breadth" and "narrowness" of treatment are in some minds artistically incompatible.

In discussing the inter-relations of science and art in artistic photography, the President arrives at a conclusion which he himself, by his able grasp of scientific progress in photography, does his best to destroy. Possibly the man who devotes himself to science and purely scientific habits cuts himself off, more or less, from the development of his artistic perception and knowledge; but a complete or a partial possession of one or both are by no means antagonistic. We have seen many excellent pictures on the walls of the Pall Mall Exhibition by the foremost man of science in photography to-day—we allude to Captain Abney—which quite disprove Mr. Davison's argument, against which, indeed, we are willing to quote that gentleman himself as a conspicuous witness. If we remember aright, Captain Abney, in the late Camera Club Conference, claimed that many artists would be all the better for considerable scientific knowledge. True enough, as his illustration of the extraordinary moons and mountains seen in some pictures amply testify. Your modern artistic photographer, whether of the "broad" or "narrow" school, must of necessity have a knowledge of photographic processes scarcely inferior to that of the scientific photographer pure and simple.

The concluding portions of the President's address, although written from the artist's standpoint, stamp Mr. Davison as

something more than an artist, and will be welcome to those who feared, and not without cause, that the majority of the Convention papers would entirely occupy themselves with the eternal art question, which is one of those things of which we conceive the most ardent disciple of the "suppression of definition" or "diffused treatment" school could have too much. The chief movements in photography during the past year are briefly described and thoughtfully reviewed in the address, although, to take one example, it seems to us a little premature to expect that "the great practical result of Messrs. Hurter & Driffield's admirable work" will be "the simplification of development for all photographers."

The President's address is throughout an admirable survey of many phases of recent photography, and it is entitled to the further compliment of the admission that it contributes plenty of matter for reflection and criticism alike. It will probably secure both.

DIFFICULTIES IN THE COLLOTYPE PROCESS.

If an opinion can be formed from the amount of correspondence we have received during the last few months, the collotype process—or, as it is termed on the Continent, Lichtdruck, and here passes under various pseudonyms—is receiving far more attention than hitherto. As in every process, so in this, those who take it up for the first time soon find that some little difficulties have to be encountered; and also that, when text books have to be solely relied upon, they are not so very easily surmounted. Hence, no doubt, the number of letters continually coming to hand recounting failures and asking their cause. From the meagre details usually furnished the questions are, in most instances, impossible to answer with any degree of certainty. To do that properly, not only should we require to know all the precise conditions under which the plates were prepared, but those also under which they were treated before printing in the press; in fact, to see all the operations performed. Usually, novices in any process are prone to attribute their failures to the formula by which they have worked, while the actual cause of trouble is rather in the conditions existing at the time. Notably is this the case with the process now under consideration, for its successful working really depends more upon conditions than upon mere formulæ.

In the abstract collotype is one of the simplest of processes. A ground-glass plate is prepared with a substratum, which acts as a bond between the glass and the printing film. This consists of bichromated gelatine, to which other substances are sometimes added. The plate is then exposed under a reversed—as regards left and right—negative, then washed and dried. It is then moistened again when it is ready for printing from, in the same manner as a lithographic stone is treated. All this appears simple enough; but there is no disguising the fact that to work the collotype process successfully, under the continually varying conditions of temperature and humidity of the atmosphere of this country, requires a certain amount of judgment, which can only be acquired by practice. Therefore beginners should not be discouraged by a few failures at first, as they are only what might be expected. With a view to the assistance of those experimenting with collotype, we will refer to a few of the more important points in connexion with the process.

One thing of great importance is the gelatine itself. One of its properties must be hardness, to withstand wear in the printing; while, at the same time, it must be freely absorbent of moisture. Generally, this characteristic is obtained by a mixture of two kinds—one hard and of an insoluble nature, and the other of a soft and absorbent character. The blending of two or more kinds in the right proportions to secure the end desired requires some little judgment. The proportions, however, that would be best in the winter would not be suitable in the summer, as the film would then be too soft, while what is necessary in summer would be too hard and non-absorbent in winter. However, a few experiments made from time to time with different samples of gelatine will determine the most suitable proportions of each quality to employ. As different batches of gelatine, even from the same manufacturers, are more or less variable, it is customary with those who work on a commercial scale to purchase a large quantity of the most suitable kinds at a time, and thus avoid unnecessary experimenting. The thickness of the printing film is of importance, as it affects the grain. But the experimentalist will soon be able to determine that most suitable for the work in hand.

A very important factor in the preparation of collotype plates is the temperature at which the printing film is dried, and this must be regulated according to the result desired—whether a coarse or a fine grain. The slower the plate is dried, and the lower the temperature at the time, the finer will be the grain, while, on the other hand, quick drying at a high temperature—within certain limits—is conducive to a coarse grain. If, however, the temperature is carried too high, and the drying effected too quickly, there may be an absence of grain altogether. The fineness, or otherwise, of the grain is also influenced, as we have just said, by the thickness of the film, as well as by the character of the gelatine of which it is composed. Hence it will be seen that no definite temperature for drying can be given, though it is sometimes done in text-books, as it is influenced by other conditions. It need not be explained to our readers that the granularity of a collotype plate is a reticulation of the film, similar to that which gave so much trouble in carbon printing many years ago, when the pictures were first developed on glass.

Next to the preparation of the plate itself, the most important point for consideration is the amount of moisture in the film at the time of printing. If too much is present, the ink will be rejected where it ought to "take," and if too little then it will adhere where it ought to be rejected. The proper hygroscopic condition of the film often proves a stumbling-block to beginners; in fact, really good printing plates are often condemned, though they have no other fault than being too moist, or, the contrary, not damp enough.

Some workers moisten the film with water alone, but the more general practice is, nowadays, to treat it with a mixture of glycerine and water, with the addition of a hygroscopic salt, such as the chloride of sodium or of calcium, "etching" the plate, as it is generally termed. When the atmosphere is very dry, more of the salt must be employed; but, when it is very damp, it often has to be omitted altogether; indeed, with glycerine and water alone, in very damp weather it is frequently found necessary to stop the printing, remove the plate from the press, and partially dry it by heat, owing to an excess of moisture being absorbed from the air while printing.

With beginners it not infrequently happens that a difficulty is experienced in getting the film sufficiently moist to reject the ink where it is not required. This may be due to the use of too hard and non-absorbent a gelatine at the onset, or to the

plate being kept for too long a time before exposure, so that the film has become insoluble or non-absorbent; or possibly it may have been over-exposed. An under-exposed collotype film will take moisture readily; a rightly timed one less so; and an over-exposed one only with difficulty, if at all. In the first case, trouble is met with in getting the ink to take on the film. In the last, it takes more or less uniformly all over the surface.

In the foregoing we have pointed out the principal difficulties, and their causes, that beginners are likely to meet with in essaying this most valuable process. The causes being known, the difficulties may then the more easily be overcome, or often avoided altogether.

DUST.*

The final aspect from which to scan this very fertile subject might be termed the chemical view, for it is with chemicals and solutions generally that it deals. In the "good old times" of wet collodion—"bad" old times the modern dry-plate worker would consider them—volumes might have been written on this one topic; for, of all things hurtful in wet collodion, dust was the most dreaded. Some of the present generation of photographers would look upon it as incredible, though it is strictly true, that at least one professional photographer had a glass cupboard constructed for the purpose, within which every plate was coated with collodion, solely to avoid the possibility of dust settling upon the film. But this is merely matter of history to the bulk of our readers, though it must not by any means be thought that wet collodion is no longer practised. One point requires far more attention, owing to its almost universal neglect—dust in washing waters. Almost every one who washes his negatives for an hour or two is aware of a fine deposit, which is rendered visible by passing a finger across the film, and the more careful workers rub each plate with a pledget of cotton-wool or some such soft material to remove this deposit, and give a final rinse before drying, that an even surface for varnishing may be secured. This deposit, in most cases, is neither more nor less than dust, though occasionally it may be traced to decomposition of the "hypo," and subsequent deposition of sulphur. Now, though it is a self-evident proposition that, the freer from dust all washing waters can be made, the better for the photographers, if it be asked how many workers take pains to guard against its admission, the reply would indicate a very, very small proportion. Are the vessels the plates are washed in kept covered? Are the tanks through which the water passes secured against the all-pervading enemy? Finally, is the water passed through a filter—coarse or fine—before passing to perform its duty? In very many cases, No!

If there is need for all these precautions in regard to negatives, doubly does the necessity exist when prints are in question, be they on albumenised paper, platinotype, developed gelatine, or carbon. It argues an extremely pure source of supply, and great care at every step against the entry of dust, when prints that have been washing in running water all night, or, indeed, a few hours, are quite as clean surfaced as when first put to wash. In many places, every print is carefully sponged and rinsed before drying, and, where many vignettes are the rule, it is absolutely necessary, where due precautions have not been taken, to perform this time-wasting work. Yet it need not be so. If every tank be covered, the washing vessel likewise, and the watered be filtered, either by one of the filters sold for the purpose, or even by means of a piece of very fine muslin or flannel, it will surprise those who have not tried the plan to find how pure and clean the prints will appear. But a word of caution. Any one endeavouring to take advantage of these hints must start with everything clean, which means cleaning out, to begin with all tanks and washing vessels before using the filtered water, and covering in all from the enemy.

So far, what may be termed mechanical dust has been dealt with; but thousands of prints and negatives are, we might almost say, daily marred or destroyed by what might be termed chemical dust. Where, as is often the case, the space is small and conveniences few for the manifold operations of the practical photographer, and, indeed, in all cases, an amount of care is needed in the handling of chemicals that is not often exercised. Hypo is spilt on the floor, it is wiped up with a towel, sponge, or cloth, and that very falsely is thought the end of the matter; for, as the "hypo" dries, a few fine crystals are left upon the floor to form one of the constituents of the ever-present dust. It is spilled upon the clothes of the operator, or his assistant, and again forms dust that may or may not fall upon a print or cling to the albumenised paper as it is hung up to dry. Innumerable cases of spotted prints, the blame for which is often thrown on the albumeniser, are produced from this one cause alone. Where the same room has to be used for all such purposes—sensitising paper, dissolving hypo, and other substances, weighing and measuring chemicals, and so forth, the utmost care should be taken to provide against any particle of chemical or drop of solution being spilled upon the floor. But of our own practical experience we are able to say that too often is the greatest carelessness displayed. A hundred-weight cask of hypo lies about; what matters one tiny crystal spilt upon the floor? A quantity of pyro is needed to be weighed in haste, it is rushed on to the scales, particles, perhaps left on the scale pan, and many of the slight fibrous crystals wafted in the air; and yet, if a spot appears upon a print done in paper sensitised in the same room, what surprise is expressed, and how the paper-maker is blamed! It may be truthfully said that the only marvel is there are so few spots, and that the loss from such causes does not mount up to quires of paper and dozens of plates, rather than the few that are heard of. Perhaps the destruction is greater than is really known. In conclusion, let us advise our readers to cover all tanks, filter all water, let not a crystal or drop of solution fall to the floor without being removed, and then some of the direst effects of dust will be avoided.

* Concluded from page 419.

An Electric Retoucher.—It is said that an electric pencil for retouching has been patented by a Rhode Island photographer. Retouching, it is claimed, will, by its aid, be made a very simple operation, and more quickly performed.

Converting Gallic Acid into Pyrogallol.—Mr. P. Cazeneuve sends a communication to the June number of the *Comptes Rendus*, in which he states that, on adding to gallic acid double its weight of aniline, the mixture congeals abruptly into a mass, with a rise of temperature. On the application of heat, aniline pyrogallate is obtained in long, instable crystals, from which the aniline may be removed by cold benzine and toluene, leaving pure pyrogallol. The melting point of pyrogallol is 132° Centigrade, and not 115° as stated by the text-books.

American Journalistic Amenities.—This is how the editor of the *Pacific Coast Photographer* writes of one of his con-

temporaries: "What a small, petty, picayunish thing the editor (or editress) of the long-titled sheet the —— is. It is a question in the minds of its seven subscribers whether a man or a woman is responsible for the editorial gibberings. No one knows; when we look at the cover we see on it a woman's portrait, but, if we *should* happen to look inside, which is seldom done by any one, we would be forced to notice an effervescence of petty bickerings and spite, which could never emanate from aught but a dyspeptic, rheumatic crank!" Hoity toity!

Toning in Thunderstorms.—In the last number of the JOURNAL a correspondent mentions that during the thunderstorm of June 28 his prints refused to tone up to the usual depth, whereas on the following morning, when the storm had passed away, the toning action proceeded as usual. We have examined the prints sent, and the difference in depth of tone, if not great, is at least appreciable. We have no experience of the implied influence of an atmosphere charged with electricity upon toning baths (by the way, our correspondent omits to describe the particular bath he employed), but it is at least conceivable that some such retarding action as that spoken of does take place. Perhaps some of our electrical readers can give an explanation of the phenomenon here assumed to be instigated.

Death of Mr. C. V. Shadbolt.—We are sorry to have to announce that Mr. C. V. Shadbolt succumbed on Friday last to the injuries which he received in the balloon accident at the Crystal Palace a fortnight ago. Mr. Shadbolt, who was only thirty-three years of age at the time of his death, had a well-deserved reputation as an intrepid and clever exponent of aëronautical photography, upon which subject he contributed a brief article to our ALMANAC for 1884, where he also made reference to Captain Dale, his companion in aërial adventure. In our issue for June 1, 1883, an article by the deceased gentleman on a similar subject will also be found, and, indeed, from time to time he contributed to our pages on a variety of topics of photographic interest. We are confident that the sympathy of all photographers will be extended to Mr. George Shadbolt and the family in their bereavement.

Removing the Yellow Tone of Gelatino-bromide Prints.—"Moncton," in the *Canadian Photographic Journal*, gives the following remedy:—Place the prints in a solution composed of a saturated solution of oxalate of potash, two parts; water, acidulated with acetic acid, one part. The immersion may last an hour or two, and the method is, says "Moncton," also efficacious for prints that have been made several weeks. The same authority also states that a one per cent. solution of iodine in equal parts of alcohol has a "fine effect." The action is the opposite to that of the bromides . . . iodine tending to produce reduction of contrast, and, if used to an excess, it will flatten the negative. "Moncton" says this is worth trying, as the effect is a very striking one. No doubt; but who wants flat negatives?

A Flourishing Photographic Society.—We are pleased to gather from the annual report of the London and Provincial Photographic Association that that body betrays the best possible signs of vitality in an increased number of members and a sustained interest in the papers and discussions which take place at its meetings. No small share of this gratifying result is due to the Honorary Secretary, Mr. R. P. Drage, to whom we are glad to find the members at the annual meeting passed a specially hearty vote of thanks. In the course of the coming autumn the Association is about to commence a series of lectures on the various branches of photography by recognised authorities, and those papers, together with the discussions thereon, will subsequently be published in book form. We hope with the Committee that this volume will prove the most complete *résumé* of photographic procedure up to date.

The Price of Silver.—Although, as a correspondent points out, metallic silver is very cheap just now, the margin between cheapness and dearness in this particular product is, after all, so small that it is difficult to see how any benefit worthy the name would accrue to photographers by manufacturers of many sensitive preparations adopting a sliding scale, for, at best, the advantage either way could but be fractional. The reason why sensitive paper remains at the price it was when silver was nearly double its present rate is not clear. Modern albumenised papers are, comparatively speaking, weakly salted and weakly sensitised, and we would therefore suppose, as our correspondent does, that they would be cheaper on several grounds. As a matter of fact, we believe sensitive paper is supplied to the trade on lower terms than was the case years ago, but the user of the paper does not always get the benefit of the reduction.

Decline of Intensification.—In the course of a brief but interesting discourse on intensification at the London and Provincial Photographic Association on Thursday week, Mr. J. S. Teape appeared to think that the intensification of negatives was not so much resorted to now as formerly, among his reasons for that opinion being the use of actinographs, &c., which he said guarded against excessive over-exposure, of slow and thickly coated plates for landscape work, backing, and emulsion papers. We are ourselves disposed to agree with Mr. Teape so far as general or every-day work is concerned and where the reservations he mentioned prevail, but the wide use of very rapid plates is, undoubtedly, still responsible for the necessity of strengthening the image in such a large number of cases that intensification cannot yet be regarded as likely to die out. The development of very rapid exposures so as to get the requisite degree of density is the *bête noir* of a great many photographers.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

EDINBURGH MEETING.

THE arrival of every train in Edinburgh on Monday signified an addition to the band of brothers and sisters of the Convention who kept pouring into the city all that day until, still some time before the commencement of the inaugural meeting at seven p.m., something like 230 names had been registered.

When Lord Provost Russell, in official robes, attended by several civic councillors and mace-bearers, and accompanied by some leading officials of the Edinburgh Photographic Society and of the Convention, entered from a side room the hall of the Royal Scottish Geographical Society, it was found that the place was already filled to overflowing, many ladies being present, several of whom had come from a considerable distance.

Mr. Hippolyte J. Blanc, Chairman of the Local Committee, and President of the Edinburgh Photographic Society, introduced the Lord Provost, and recognised his kindness in being present when he knew that other engagements claimed his presence elsewhere almost immediately.

The Lord Provost expressed the great pleasure it gave him in welcoming to the city of Edinburgh the Photographic Convention of the United Kingdom, who were exponents of the present state of photographic art. To realise the advancement photography had made since its early days, they had merely to compare the first Daguerreotypes with the exquisite productions of the present day. Some had said that photography could not be associated with the fine arts, but the sun was merely a brush by which a man produced his individuality on his photographic works. Referring to the possibility of producing photographs in the colours of nature, he said it was, even more than photography itself, in its infancy; something had been done, and much might be anticipated. There was no doubt as to what it was doing for science. Astronomical science in particular had been greatly indebted to photography, which had demonstrated the existence of suns and systems invisible to the eye even when aided by the telescope. However, their great pleasure would at present be in seeing photography developed as a fine art. He hoped the Convention would have a very happy time while in Edinburgh, and that the weather would prove auspicious for their projected excursions.

Mr. C. H. Bothamley, who presided in place of Mr. Bedford, the President, who was absent through illness, returned thanks to the Lord Provost for his welcome. Edinburgh was, both in itself as a city and in its surroundings, replete with historical subjects, which would afford ample themes for the exercise of their cameras during the week of the meeting, and the kindly welcoming of her chief magistrate was and would be much appreciated. He then introduced the new President, Mr. George Davison, who delivered the opening address.

PRESIDENT'S ADDRESS.

I WISH, at the outset of our Edinburgh meeting, to give expression to the lively feelings of interest and sociability with which, I am sure, photographers from all parts have come together to confer and fraternise with their comrades of the northern capital.

A PLEA FOR THE CONVENTION.

Of all the conventions, conferences, congresses, and association meetings which are organized to further the interests of various pursuits, none, I think, can be held to be more appropriate to a summer gathering than a reunion of photographers, whose practice naturally leads them at this season of the year so greatly to outdoor occupation; and at no place in the provinces more than Edinburgh, in itself, its surroundings and its photographers, could there be greater certainty of finding stimulus to artistic practice as well as to scientific inquiry in photography. It seems natural and right that photographers should gather in this sociable way each summer, and particularly happy that they should meet in this beautiful city on an occasion when the heads of the organization have signified in some sort their recognition of the artistic applications of photography by seeking as president our veteran in the art, Mr. H. P. Robinson, and, failing him, one younger, though not less enthusiastic in devotion to the same branch of camera craft. I have faith, then, that the cordiality and sociability, characteristic of the camera, will, in conjunction with a sympathetic seeking of the beautiful, be specially marked and remembered in connexion with this Edinburgh meeting. Notwithstanding the jealousies and quarrels of specialists, which indeed may be regarded as significant of superabundant life and energy, there is certainly a sympathy felt wherever a fellow-worker in photography is met. As the use of the camera becomes more and more universal, such sympathy and unity may become less and less noticeable, but in the early history of any pursuit they are an important factor in progress. It is to be hoped that, despite all passing dissensions and personal differences, photographers will always foster the fraternal spirit prominently witnessed in the very idea and existence of the Convention we are now holding.

On looking around at the general position in which photography is found to-day, I think there is room for satisfaction at the activity and promise displayed. Photography is extending its borders in every direction. In its capacity as handmaid to other sciences and arts, and in its industrial applications, there seems no limit to its utility. Directly, as a profession, or as a pastime, it also grows apace, and I can see little justification for the prophecy we have all heard that the rage for photography would die out as did that for rinking. So far from this being the prospect, photography, with its attendant incitement to the study of light, optics, and chemistry, its cultivation of the powers of observation, general and artistic, and as an indispensable means of record for travellers, has become a necessary concomitant of our advancing civilisation, and seems likely to extend its influence until the camera will occupy a place in every educated household as naturally as the piano and even, in some sort, will be made part of the ordinary education of every boy and girl.

PICTURE-MAKING NO WASTE OF TIME.

Having said so much in regard to the general outlook, I propose to direct my remarks chiefly to one particular aspect of our progress in photography, namely, the art aspect. It was, indeed, with some doubt and diffidence concerning my topic that I accepted the honour of the presidency of this year's Convention. In being called on to address the large body of practical and scientific men who impart life and usefulness to this organization, and, through them, to speak to many photographers as well as the general public, I felt I could say nothing in technical criticism of recent purely scientific advances or inventions in photography which would not have been already better summarised and explained. Apart from a general and popular interest in these improvements, such observations as I have been able to give have been, as you know, directed in a different channel, and it is only as these new developments and discoveries have seemed to me to have a bearing upon pictorial work in photography that they have had any great attraction for me, and that I feel able to discuss them. I shall have, therefore to ask for the patience of those who, by some misfortune in their constitution, hold that mere picture-making is a waste of time, and that it is only in its applications to science and the industries that photography should be seriously regarded. Despite the expression of such views, I deem it unnecessary, at this date, to argue that photography is capable of direct artistic application. Such a position, you will generally agree, it would be absurd to gainsay. The exact extent or limitation of the powers of photography in this direction is a very different matter. New means and new methods are being constantly introduced, and it will be best to leave it to time and steady effort to prove its capacity and its limits. I welcome, however, this public opportunity of renewing, to the fullest reasonable extent, the art claims of photography, and of inciting all photographers with artistic tendencies and ambition to inquire into and apply to their purpose every new means, method, instruments, or practice, which science can devise, or which their insight and needs call for and suggest.

"SUPPRESSION OF DEFINITION."

I think the state of photographic art at the present time is not without encouragement. It has passed through several phases. It started under the friendly auspices of recognised artists, many of whom seemed to expect that it would do, automatically, more than, even with training, it can be made to do; and later, when their disappointment came, it has suffered from an equally unreasonable excess of opposition from some of a certain class of painters, who, while using it, find it possible, at the same time, to roundly abuse it. Early in its history it discovered one or two who understood and mastered some of its powers, and that work remains a marvel of excellence and strength or a triumph of skill in the handicraft.

To-day interest in its development has been freshly roused by keen discussions as to the distinctive qualities of photography, as to the naturalness of certain methods of focussing, as to tone relations, and as to the qualities yielded by the several printing processes in respect of gradation, surface, quality, and colour. I am of opinion that there has been a great advance made, and that the improvement is still going on. It has been stated that the imparting of superior artistic qualities by the suppression of definition was an old idea, and had been ably and exhaustively discussed in London societies thirty years ago, and that the present movement would probably die out as that died out. I do not think this is a safe forecast. I have not thought it worth while to inquire how ably and exhaustively the matter was thrashed out, but I cannot but think it must have been a one-sided view, as far as the photographers in those societies were concerned, for none of them seem to have had the courage of their opinion to practically and adequately illustrate the broader treatment. It is a very curious circumstance that almost the only valuable artistic survivals from that period are in that particular broad focussing. I refer to Mrs. Cameron's powerful and original pictures, which, to-day, are universally admired. However, the present movement is not confined to matters of focussing, nor is it due to any individual, or clique of individuals. The general result of it is happy, in that many photographers have been set thinking and working, and more general and special recognition of the artistic powers of photography has resulted. Only a few days ago a well-known and very popular painter, referring to certain pictures of the class indicated, said to me that he wished he had one or two representative photographs of the kind for his painter friends to see. They were quite unacquainted, he said, with what was being done, and could be done, in this direction, by photography. Painters could not be induced to visit photographic exhibitions, and were prejudiced by the great mass of ordinary photographs which are displayed in the shops. In the same way Mr. Seymour Haden recognised in these photographs the power to seize on beautiful impressions of a subject, and secure what he termed painter-like qualities.

"DIFFUSED TREATMENT."

Do not let it be thought that I wish to arouse afresh any bitter controversy as to the relative merits of different kinds of focussing. Impressions differ, and truth and naturalness in these matters are as various and defensible as the likes and dislikes of different people. We shall do well to keep each of us to the truth that seems the best truth to us, after fully and fairly trying all; or, better still, to cultivate that frame of mind which leaves us free to apply any and every principle or plan as it seems best to suit the purpose in hand. I frequently see photographs which would be considered quite sharp, possessing most charming qualities, though generally in the direction of the beauties of the miniature or the somewhat rigid steel engraving. My own preference is greatly in the other direction. Photographs in various degrees and qualities of diffused and differentiated focus may still be deficient in some essential quali-

ties, but the general tendency of this treatment seems to me to leave open greater possibilities of securing the broad character of a subject, what has been referred to as painter-like qualities. I do not think it necessary to discuss in detail how far, or if at all, the beauty lies in the use of a rough-paper medium or in diffused treatment; I simply indicate that their tendency appears to me to be towards affording greater scope for, and likelihood of, securing the general sentiment, as opposed to a more detailed and decorative interest in the resulting work. It may be that this is merely a fashion, a conventionality in art; but, if so, the conventionality is there, good or bad, and it is certain that results by these methods best please those who have had artistic training. It is merely an accident—or a natural consequence, if you will—that these pictures are open to be mistaken, and are mistaken, for sepia drawings. In the same way, sharp and glossy photographs may be called imitations of the still older miniature paintings. No one method has a monopoly of all qualities. The artist in miniatures may have as much perception as the impressionist of broader treatment, although it be a different perception. It will be best, perhaps, to consult and abide by our individual preferences in this matter, as also in that of the much-discussed question of composition, where there may be a preference for the fascinating excellence and subtle combination and direction of line and arrangement of light and dark in spaces, or, on the other hand, for the charm of naturalness of effect and the spirit and character of natural scenes or incidents. The attitudes in the cultivation of these two excellences are somewhat opposed to each other, and the man who marries the two in his expression by painting, and without seeming effort, is the genius we may all conspire to worship.

Relation of Science to Art.

Here I am reminded of the very interesting discussion as to the separation or relation of science and art, which has recently gained some prominence in our societies and journals, and which seems particularly prompted in connexion with photography. The photographer, especially in a new and growing art, and one in which the tools are less simple and direct than in other more definitely handicraft arts, cannot afford to disregard any new weapon which seems to promise aid to his purpose, whether given by science or prompted by the practical necessities of other workers. At the same time, any interest in science or mechanical work, apart from its application to the one pictorial end purely, cannot fail to vitiate the character of the result from an artistic standpoint. The argument is the same as in the painter's art. There is a large tract in the domain of the artist altogether uninvaded by science, as the term is reasonably understood. A great painter may be practically scienceless; his knowledge of appearances may have been gained in an unscientific way, and better so. He sees, he knows; and the process of his observation and knowledge, and of the expression of his message, is at present past finding out. At the same time, it cannot be said that artists are better without science. It is, indeed, to their advantage to make use of every new fact and discovery; and art in the present day seems to require more and more erudition. An absolute scientific falsity is a distinct blemish. The case cited by Captain Abney of the painter who painted a rainbow inside out in respect of the sequence of colours, and then charged twenty guineas for setting it right, is a good, if apocryphal, instance. Mr. H. P. Robinson pointed out that the picture was not less beautiful in one way than in the other, and this is true as far as ninety-nine out of a hundred observers would be concerned; but, in so far as the painting is for all, and that spectrum analysts have probably still some slight interest in pictorial art, their feelings ought to be considered, and such a defect should certainly have been wiped out, and without charge. A picture may be great and beautiful in its truth or its fancy, in spite of many technical and scientific ignorances, but it would be better still without such blots. A great natural genius may, straight out of the heart of nature, draw beauties in a way that a student of the very latest theories of light relations, perspective, focus, colour, would miss altogether, but still it is of the utmost importance that all this knowledge should become part of the equipment of every new man who feels a mission to move our susceptibilities by graphic art. It stands out clear that for the average man the two paths of science and art lie apart or diverge. The man who devotes himself to science and to purely scientific habits and research thereby cuts himself off, more or less, from the development of his artistic perception and knowledge. The sciences of colour, and light, and biology, and the knowledge of kindred sciences necessary to master these, form a life work for any one man, as do also the science of appearances and the cultivation of the powers of expression and skill in selection and arrangement. Each man has his natural bent. Nature does not yet exhaust herself in one great stroke by reconciling in any one existence or work the seeming contradictions of science and art.

An Institute of Photography.

Adverting to somewhat more practical matters in connexion with recent photographic affairs and events, it is hardly possible to pass by altogether, on such an occasion as this, the temporary excitement which has been roused concerning a Photographic Institute, and other attempts to organize concerted action in the form of photographic surveys, geological, local, archæological. Some good work has been instituted in the latter directions by scientific associations, and by a few energetic provincial photographic societies, but it seems to be a matter of some difficulty to secure anything like combined action amongst photographers. Such an end can only be attained by associating those interested in the several applications of photography. The great schemes for an Institute of Photography, in which students could be adequately taught and trained in photo-mechanical processes, in industrial applications of photography, and in methods of scientific inquiry, seem unfortunately to have now been lost and forgotten, notwithstanding the admirable outline suggested in the paper read by Professor Meldola. If such a College or Technical Institute is to have promising initiation, the first steps must evidently be dissociated from any one association or clique, and even from those who might be called on for some support, namely, those directly interested in photography commercially. Speaking as a practical organizer, I think that with a purely scientific and practical body urgently called together, in the first instance, by such a committee as Captain Abney, Professor Meldola, and Sir Henry Trueman Wood, and chiefly composed of certain representatives from the leading scientific societies—astronomical, chemical, engineering, meteorological, and the like—a dignity would be imparted to the movement which would possibly secure wealthy, energetic, and influential support.

The initiation of a nationally useful enterprise of this kind might be held to come within the scope of the work of the Society of Arts, seeing that the movement is so intimately associated with progress in science and in art, and aims to fill a gap which constitutes a national misfortune. Under the auspices of an independent and powerful organization the undertaking should surely meet with success, and there would no longer be felt the frequent necessity for going abroad to find practical craftsmen in photo-mechanical processes. The question as to whether photographic art should be included specially as a study in the curriculum of such a college seems to be a matter of divided opinion. For myself I hold there is very great scope for teaching in this direction, and such an institution could not be considered complete without due provision for instruction in portrait and landscape picture-making. At the same time a *complete* photographic college with laboratories would be a great task to contemplate at the outset, and the first, and most probably self-paying, department which suggests itself is instruction in photo-mechanical processes. Probably one of the best introductions to the initiation of an Institute movement would be the holding of a fully representative photographic exhibition, in which the many applications possible to photography should be practically illustrated in separate scientific departments, and the art section placed separately. In face of a cry for a technical school of instruction in the industrial, scientific and artistic applications of photography, it is a matter for some surprise that such an exhibition, which would be the best practical evidence of the opening and scope for a teaching Institute, has not been arranged. I believe it would prove a natural and easy step to what is desired.

A Record Office—Photographic Exhibitions.

Suggestions have also been revived for the foundation of some kind of State record office, and the value of permanent photographs of many subjects, objects, and individuals in the future would, if judiciously classified, certainly be found to be as great as that of most printed and written documents, some of which, indeed, are priceless. But there seems to be great difficulty in making and centralising such collections, and each division of applied photography is left to make its own disjointed collections. There is a gallery, or portfolio, of photographic portraits of prominent men and women in course of accumulation, due to the initiative of the Amateur Photographic Association, and deposited, I believe, at South Kensington Museum. Such permanent photographs, more particularly if free from much, or any, retouching, should, in time, help to prove the need for a still more extended work in the same direction.

The subject of photographic exhibitions naturally finds a place in my remarks. I think the tendency in that respect must, from an artistic standpoint, be held to be satisfactory. The more it is regarded, the more, I am sure, it will be seen that any system of classifying artistic pictures, and judging and giving medals to them, is out of place and objectionable. The public interest which is now felt in all the leading exhibitions is quite sufficient to form an inducement in

those cases for exhibiting, and the smaller local exhibitions may be left for the moment out of consideration. The best argument to be adduced in support of this view is the success which has attended the International Exhibition at Vienna, the English Exhibition at Brussels, and the practical repetition of this latter at Lincoln, in all of which, by selection and invitation, a better average of excellence and a far greater credit to photography have been the result. In this connexion it will be remembered it has been a frequent custom to divide the art section of photography exhibitions into amateur and professional classes. For this, I think, there can be absolutely no defence if the exhibition has any pretensions whatever to be called an art exhibition. In art there can be no division of amateur and professional in the common acceptance of the terms. For the requirements of defensive trade union, or for club and general distinction, the division may be deemed advisable or not, but in art there is only quality—the good and the bad—whether the pictures be for sale or not.

Referring briefly to some recent inventions or introductions which appear to have some relation to art photography, we come first upon the great excitement of photography in natural colours. There is nothing practical as yet in this respect to deal with; but as two of our foremost photographers—one in science, the other in art—have, in the interests of artistic appearances, deprecated any such discovery, may we not ask why this should be so? Should we not rather welcome, with the keenest enthusiasm, a power of colour, confident of ability to avoid the commonplace and the mechanical, and of success in applying it to direct artistic purpose?

New Lenses.

In lenses there have been the tele-photographic combinations, introduced here by Mr. Dallmeyer, with which magnified pictures of distant objects, little short of marvellous, are produced, and which, in some cases, it is quite conceivable would be applicable to an artistic purpose. Quite recently the concentric lens of Messrs. Ross has been described and introduced, and this would appear to give the power of diffusion of definition, accompanied by rapidity. How the quality of the definition compares with that of the patient pinhole, I cannot say; but, as far as I have any experience, I have not yet seen any quality of definition so pleasing as that yielded in diffraction photographs, and I would strongly urge the more extended use of pinhole photography. In connexion with lenses for artistic purposes this opportunity may also be taken of drawing attention again to the use of large single lenses opened out to an intensity of *f*-4 or wider, as employed by Mr. Lyonel Clark for portraiture of large heads. The excellent results obtained by him certainly justify and call for a more general practice of the method. Under the head of control by means of lenses, I may refer in general terms to a method of local control, which, I understand, Mr. Van der Weyde has devised, and of which he will shortly give a full description. By this method the relative proportions of features in portraits or of objects in other pictures can be altered at will. The relative increase or diminution of parts can be carried to any extent, and it is evident that the process will be possible of both artistic and grotesque application.

Passing on one step, there has been considerable attention devoted to aids to exposure, particularly in Messrs. Hurter & Driffield's system, on the ground that only by exactly correct exposure can the true relative gradation of a subject be secured. Speaking merely from practical experience, in landscape work, however, the differences in general quality and character in prints from negatives which have received various degrees of over-exposure are not appreciable, provided that a thickly coated sensitive plate be used, and the development be arrested at the right time. The great practical result of Messrs. Hurter & Driffield's admirable work seems to me to be the simplification of development for all photographers. In regard to sensitive plates for the artist photographer, the tendency must, doubtless, be in the direction of thickly coated and orthochromatised plates used with screens. In regard to thick plates, what, as far as I know, is a new departure has been made by the introduction of a plate with emulsions of varying rapidities coated one upon the other, thereby giving great latitude in over-exposure, and greatly obviating halation, one of the most insidious and often unsuspected causes of trouble to the photographer.

New Printing Processes.

It is, perhaps, in respect of new and modified printing processes that the artist photographer of to-day can be most congratulated. No finer results have ever been produced in colour and general quality than the prints obtained by Mr. Lyonel Clark in working what is now known as his toning process in connexion with rough-surfaced papers. There is, however, the doubt of permanency; and the practical and uncongenial difficulties and uncertainties in the preparation of one's own paper are great objections for the artist, who requires all his attention in other directions. Similar appearances have been obtained in bromide papers, and, with the advantage of permanency in platinotype and carbon, and of the newer methods, the interesting kallitype process might, perhaps, be applied in the same manner. A striking novelty for the artist photographer is the method recently introduced by Mr. Willis of controlling the character and effect of platinotype prints by slow local development with a brush, the development being retarded by preliminary treatment of the print with glycerine. The beauty of some of the results by this means in the hands of a competent painter photographer is very noticeable.

Photo-Mechanical Processes.

Turning for one moment to photo-mechanical processes, there is not much that is new which would seem to have any special application to artistic photography. The use of photogravure by the general worker has not extended as was anticipated, owing, perhaps, to the practical difficulties to be surmounted, and to the greater satisfaction felt in the production of a single direct print superior in most cases in quality to what the engraving process would yield in numbers. As regards photogravures and other photographic reproductions of artists' pictures and drawings for framing and for journal illustration, there is still much jealous opposition amongst artists and some hangers-on of the press, who take their cue from these artists as to the quality of such reproductions. No doubt, in the cheaper processes, the general gradations of the picture may be modified if the loss be not obviated by special preparation of the picture; but, at the same time, there is retained in these processes or photogravure reproductions so much more of the character and originality of the artist than is seen in any but the very best wood or other engraving that there can, it seems to me, be no doubt about their becoming more and more used.

I have tried to indicate the state of photographic art amongst us. I think we may be proud that there is more interest in pictorial photography, and greater advance in this respect in our own than in any other country. It is hardly fair to form a judgment from the harsh, uninteresting, and even grotesque illustrations which are from time to time given in foreign photographic journals, as even those in our own photographic magazines are often very little better; but there are other means of judging of the standpoint in this regard of our brethren in France, Belgium, Austria, Germany, and America. I can only say it would be better, in all cases, if these ill-judged illustrations were omitted.

In conclusion, let me urge that we should not fail in keeping up and standing by the dignity and just claims of what we profess and practise. I think I see in the past a steady and even a rapid progress in art photography, and in the future a hope of still further advancement and of a better position. It is this spirit that has animated me in addressing you, and, instead of having to appeal for tolerance, I feel I may make bold to claim a fervour of agreement from you, a union against all enemies, and a combining to overcome all obstacles to our progress.

We shall be sustaining the true and fitting spirit of this Convention if we can all continue to advance together in the science, the art, and the good fellowship of our common object—photography.

Mr. Crooke, of Edinburgh, proposed a vote of thanks to the President for his very comprehensive address, in which so many phases of the art had been introduced. This was seconded by Mr. W. Lang, jun., of Glasgow.

The President, in acknowledging the vote, said that they had with them on that occasion some photographers from a distance, namely, Miss Catharine Weed Barnes, who represented photography in New York, and Dr. Mitchell, from Philadelphia. Mr. F. E. Ives had written to say that greatly to his grief he could not carry out his intention of being present and reading a paper, as had also Dr. Liesegang, of Germany.

Mr. J. Traill Taylor moved the thanks of the Convention to the retiring President, Mr. William Bedford. This gentleman, he was sorry to say, was unable to be with them on account of serious ill health, being prohibited by his doctor from leaving his room. Mr. Bedford has been most assiduous in attending to his duties; he was a man of great value, and emphatically one who was most excellent in counsel. He would couple with his vote of thanks one of condolence with Mr. Bedford in his present affliction.

Mr. Cembrano, Hon. Secretary, seconded this, which was carried unanimously.

Refreshments having been partaken of in an adjoining room, the

party thereafter assembled in the main hall, where a lantern entertainment was provided which occupied the time till a late hour.

On Tuesday morning a party of about ninety availed themselves of the first excursion, which was to Melrose and Dryburgh, under the leadership of Mr. Hippolyte J. Blanc, A.R.S.A.

It is at present a little difficult to say how many members are present at the Convention; but, from the number of names registered previous to the formal opening of the proceedings on Monday evening, a fair idea may be had. The greatest geniality and enthusiasm prevails, and the meeting is unanimously voted to be a great success.

On Wednesday morning a public meeting, for the election of the General Committee was held. Mr. Davison, President, occupied the chair. Those conversant with the rules of the Convention are aware that it is from this Committee that the Council are elected. Mr. Cembrano, Hon. Secretary, read applications from the Devon and Cornwall Camera Club, Plymouth, the Shrewsbury Camera Club, and the Photographic Society of Ireland, Dublin, each requesting that the Convention would honour their respective places by holding the next meeting there. Some discussion took place as to whether Plymouth or Dublin should form the next place of meeting, but seeing that a tacit understanding had been arrived at last year in favour of Plymouth, it was eventually, and unanimously, agreed that the meeting for 1893 be held in Plymouth.

The President referred to the readiness and grace with which the Lord Provost had inaugurated their proceedings, and to his address, which displayed an intimate acquaintance with the nature and scope of photography, and proposed a vote of thanks to him, which was carried by acclamation. Thanks were also proposed to the Trustees of the Board of Manufactures, who had kindly granted the use of the fine hall in which the meetings were held, and to the Edinburgh friends whose exertions had so greatly conduced to the success of this year's Convention.

Mr. Bothamley proposed, and Mr. Davison seconded a vote of thanks to Mr. Cembrano, the Hon. Secretary, whose labours had been very great and very successful. This elicited three cheers.

In responding, Mr. Cembrano said that he was gratified in being able to announce that in numerical strength the present Convention has beaten the record, the number of members being greater than that of any former year.

The following were elected as Council for the ensuing year:—

Bedford, W., London.
Blanc, H. J., Edinburgh.
Bothamley, C. H., Taunton.
Bridge, F. A., London.
Brigginshaw, J. J., London.
Carnell, A. A., Plymouth.
Cembrano, F. P., Richmond.
Cowan, A., London.
Drage, R. P., London.
Ewing, J., Aberdeen.
Evans, F., Chester.
Gibson, J. P., Hexham.
Handsworth, Worth, Plymouth.
Harding, Martin J., Shrewsbury.
Hastings, H. M., London.
Henderson, A. L., London.
Hepworth, T. C., London.
Keene, R., Derby.
King, Austin J., Bath.
Lange, Paul, Liverpool.
Lang, W. jun., Glasgow.
Levy, A. M., London.
Lucas, C. Phipps, Eltham.
Mason, George, Glasgow.
Mackie, A., London.
Naunton, W. W., Shrewsbury.
Porritt, J., Leicester.
Pringle, A., Bexley Heath.
Sayce, B. J., Liverpool.
Seaman, A., Chesterfield.
Smith, H. M., London.
Sturmey, H., Coventry.
Stuart J., Glasgow.
Taylor, J. Traill, London.
Tate, A., Belfast.
Turnbull, J. M., Edinburgh.
Warnerke, L., London.
Webster, G. W., Chester.
Wellington, J. B. B., Harrow.
Werner, A., Dublin.

The members thereafter proceeded to Princes-street Gardens, where some groups were taken by Mr. Alexander Ayton and others. The number present was very great, but the posing was effectively done by aid of the shelving rocks at the base of the Castle.

In the evening the following papers were read:—*Individuality in Photography*, by H. P. Robinson; *The Art of Photography in relation to Painting*, by A. Burchett; *Amateur Photography in America*, by Miss Catharine Weed Barnes; and *On the Training of Photographers*, by E. Howard Farmer. These, together with a description of the proceedings, will be given in our next. Fortunately, during the earlier part of the week the weather was fine.

Apparatus and Pictures.

The display of apparatus and pictures is not, numerically speaking, very great, but is unusually excellent.

In pictorial display first come the Eastman Company, who cover one end and a large portion of the side of the hall. Their exhibits mainly partake of the character of enlargements, which, speaking quantitatively, are the largest that have probably ever yet been seen. Their perfection is marvellous, especially seeing that there is but little of the work of the retoucher or finisher to be seen on them, one, indeed, *e.g.*, a view in Chiddingstone, by a former secretary of the North London Photographic Society, being absolutely untouched both in negative and enlargement. Several are from negatives by Thomas Fall, Lafayette, H. Yeo, and others in this country; and others by Van Bosch, Boyer, and other Parisian or French artists. This Company also exhibits a large collection of prints taken direct on their new chloride printing-out paper.

Morgan & Kidd show many fine enlargements from small negatives by Van der Weyde, and others. It is to be regretted that a catalogue of such exhibits is not specially prepared, as it would have greatly facilitated reference.

There are several carbon enlargements by M. & T. Scott, one of special excellence being a large group of more than a hundred figures by Alexander Ayton, jun., of Edinburgh, in which the posing (a difficult matter) has been happily managed.

There are also excellent enlargements by Elliott & Son, and by John Patrick & Son.

In apparatus there are lantern microscopic attachments by C. Baker; Wood's paper-cutter; a large collection of scientific apparatus, lanterns, and hand cameras, by Andrew H. Baird of Edinburgh; and an exhibition of lantern appliances in form of cylinders and pressure gauges by the Scotch and Irish Oxygen Company.

Messrs. Wray have a case of their lenses; but, as it is covered in, we can only surmise that they are of the same high-class character for which the productions of this firm are so well noted.

William Hume, of Edinburgh, exhibits enlarging apparatus of various kinds, including his Cantilever and Nimrod lanterns, the reputation of which has been long established.

Watson & Sons, of London, show their admirable Acme cameras, extensively fitted with aluminium metal work, which is both light and rigid.

Geo. Houghton & Son have a good exhibit, which includes their Shuttle haud camera, of which we gave a description quite recently.

As for kodaks, they are here in every size and form, together with the variegated productions of the Eastman Company, in the form of roll-holders, dark slides, spools, and other appliances. Mr. John Jackson at one end of a long table, and Mr. H. M. Smith at the other, were busy at the time of our visit in demonstrating to Edinburgh professionals and amateurs the toning and fixing of the Company's new paper, which appeared to give great satisfaction to those concerned.

Rodinal (the new developer) is also in force, and specimens are on exhibition, together with instructions for using the same.

The showroom attached to the hall being insufficient to contain the large exhibit of George Mason & Co., of Glasgow, this firm has opened special and temporary premises in Waterloo-place, in which to show their goods. These comprise all the novelties of the year, and include new American background stands, Morgan's graduated backgrounds, new American paper and mount-cutters, Ross's lenses (including the new Concentrics) in brass and aluminium, Zeiss lenses, Mason's patent tripod securers, instantaneous shutters by all leading makers, "Globe" nickel-plated burnisher, the "Amateur" burnisher (various sizes), cameras for studio and field (from quarter-plate to 24 × 24), Scovill's American studio cameras, tripod nets in which to lay holders and diaphragms, magic head screen, new head rest with ball and socket arrangement, Mason's lantern-slide "Binocular Photoscope," focussing glasses (numerous patterns), photographic chemicals, graduated measures, chemical balances, dark-room lamps, retouching desks, printing frames (in oak and mahogany), grooved fixing and alum troughs,

studio accessories—a large and varied selection, including cottage background, tree stump, balustrades, gate and wall, bird-cage, oak tables (various), chair (three backs), chair (four backs), electric bells, and telephones)—photographic literature, negative and print washers, developing dishes, camera cases and stands, studio stands of various patterns, new and improved enlarging lantern, aniline and other colours for tinting photographs.

Since writing the above, several additions have been made to the apparatus in the hall, to which we shall refer next week.

A NEW FORM OF ETHER-OXYGEN LANTERN.

[Royal Society of Canada.]

The difficulties commonly incident to the preparation and manipulation of the oxyhydrogen light have led me, after a series of experiments extending over many years, to devise and construct a form of optical lantern which may be quickly and easily operated with the least expense and danger, and in which compactness is secured together with an avoidance of excessive weight.

The apparatus has been designated the Ethoxycon, as indicating the use of ether and oxygen. It combines both the lantern proper and the gas generator and storage bag or receiver. In general terms, the generating and storage parts consist of a generator or retort for the production of oxygen gas, a filter or washer, a saturator, a regulator, and a storage gas receiver. All of these, together with the lantern proper, are contained in a box or case, which measures 10 × 18 × 18 inches. This also serves as a stand for the lantern when in use.

The details of construction and operation are as follows:—

The lantern proper, or the optical part of the instrument, consists of the ordinary lens system for enlarging, projecting, and focussing the image of the object as illuminated by rays of light passing through a condenser. These parts are all comprised in a small case of wood and metal, in which is placed a four-inch condenser, this size being ample to cover the aperture of an ordinary lantern slide three inches square. The back case of the lantern is provided with a sliding adjustment to establish the proper focal relations between the lens and the condenser. The spindle upon which the lime is placed is also provided with the usual means for transverse and vertical adjustment and adjustment of the jet relatively to the lime. An important feature consists of means for vertical adjustment of the entire instrument. This is effected by having the body hung on pivots at the summit of two metal triangles. From each pivot there depends an arm, carrying at its lower extremity a clamp operated by a thumb screw. This latter passes through and engages upon a short arc opening in each triangle in such a way that the body of the lantern may be adjusted horizontally, or vertically above and below this position within an extreme range of about 30°, the position desired being firmly secured by the clamping action of the thumb screws.

The generator consists of an iron or steel tube, with a semicircular cross section. Into the flat or lower side are inserted a number of copper cups, each of a capacity to contain sufficient mixture to maintain the light for about fifteen minutes. The different rates of conduction in the two metals of the retort serve two purposes. The copper, being a rapid conductor, brings about a speedy fusion of the chloride of potash, which quickly gives off gas. The iron, by its slower conductivity, serves to retard the transmission of heat from cup to cup, thereby prevents action taking place in any cup not directly heated, and secures complete control of the whole operation. Each cup is heated in turn by means of a spirit lamp or a small Bunsen burner, as may be desired, the transfer of heat from one to the other being effected automatically by an attachment which is operated by the receiver when the gas has reached a certain degree of exhaustion.

The washer, saturator, and regulator are combined in one piece, measuring 7·5 × 12·5 × 30·5 cm. This is placed directly beneath the body of the lantern between the triangular supports. The central longitudinal section is occupied by the washer. This consists of a tube arranged with fine wire cloth, and filled with a moist filtering substance, which serves to arrest any particles of carbon or other similar impurities which may pass over from the retort. On each side of the washer is a similar tube filled with pine-wood sawdust, which is charged with sulphuric or petrolic ether, as may be desired. The form of saturator is an improvement upon that usually employed, while the construction is such as to avoid all possibility of explosion. Towards one end, and directly over the washer, is a small standpipe with two stopcocks and a regulator. The latter consists of a rubber diaphragm, upon which rests a lead disc weighing about 136 grammes. The amount of gas passing through from the regulator to the burner is determined by the adjustment of two needle-point valves, one for each gas, and thus the production of a brilliant light is readily secured.

The gas-receiver is contained in the case which holds the entire instrument when in transport. It consists of a rubber bag, having a capacity of nearly one foot, the upper part of which is formed of a tin pan working upon two upright metal posts, one of which serves as a tube for the conveyance of gas to and from the receiver. Into the pan there is loosely fitted a second pan, designed to be filled with water in order to establish the necessary pressure. Upon the front edge of the first pan are a number of catches designed to engage a spring and automatically transfer the source of heat from cup to cup as the pan descends during the exhaustion of the contained gas.

To place the lantern in operation the case is located in the desired position and all the movable parts are removed. The loose pan is next filled with water to about two-thirds or three-fourths its capacity and placed in position. The rubber tube supplying gas to the receiver is next attached to its corresponding metal tube and passed through a hole in the cover made for this purpose, the latter being then closed down. Two metal rods projecting from the front of the cover are then drawn out as supports for the retort, and the lantern is placed in position on the top of the case.

Black oxide of manganese ($Mn O_2$) and chlorate of potash ($K Cl O_3$) in the proportions of 1 : 3 are now thoroughly crushed and mixed. If the crystals of chlorate are fine, thorough mixing with a spoon will suffice, but if large it will probably be found better and more expeditious to pass the mixture through an ordinary coffee mill. A metal trough of the form and length of the retort is now filled with the mixture, passed into the inverted retort, the whole reversed and the charger or trough withdrawn. In this process each cup will be filled, and any excess of material discharged as the trough is drawn out. The head of the retort is next firmly clamped on, the retort is placed in position on its supports, and the lamp adjusted to the first cup on the right. A large rubber tube is now connected with the retort at one end and with the washer at the other, while the small tube leading from the receiver is also attached to the washer. After making certain that all connexions are perfectly tight, heat is applied. If sufficient, gas will form in two and one half minutes, the first indications of which will be in a slight action of the receiver, followed by an elevation of the regulator to its full height. The pan now rises rapidly, and, under favourable conditions, the light should be on the screen within five minutes from the first application of heat to the retort. When alcohol is used in generating the gas, a somewhat longer time must be allowed for.

The distribution of the gas takes place in the following manner: As fast as it generates it passes from the retort to the washer, whence it returns by a smaller tube to the receiver, in which the surplus is stored. From the washer it also enters the standpipe and regulator, which latter determines a uniform pressure in the gas supplied to the jet, thereby securing a steady light. From this point, as regulated by the needle valves, the gas is led by two separate channels to the point of consumption. One valve transmits pure oxygen directly from the washer. The other causes a certain volume of oxygen to pass downward into one of the saturators, from which it passes into the second, and thence directly to the burner. In its course it becomes supersaturated with ether, and therefore constitutes the substitute for the ordinary hydrogen gas employed where separate gases are used.

The capacity of the retort is such that sufficient gas may be generated to operate the light continuously for about two hours. Two or more retorts will be found of advantage, and by their use continuous service may be secured for any length of time.

The exhausted charges may be speedily removed from the retort by placing the latter on end under a tap and using a free supply of water. If the latter be heated, the operation will be facilitated. If not immediately needed, the retort may then be placed on end with the mouth downward, to thoroughly drain and dry. No accumulation of moisture should be allowed, since it passes into the tubes, clogs the passage of the gas, and tends to produce a unsteady light.

The washing tube should be cleaned out occasionally with fresh water to prevent clogging. The saturator needs only occasional replenishing. With due attention to these directions and the ordinary prudence which must at all times be exercised in the use of highly explosive substances, this lamp is capable of affording a brilliant and satisfactory light, with perfect safety to the operator and a minimum of expense and trouble. The cost of operating the lamp, so far as can be determined from present experience, is about fifteen cents per hour.

The apparatus is patented in Europe and America.

George R. Prowse.

Our Editorial Table.

A Photograph and How to Take It.

By "One Who Knows." Thirty-second edition.
London: E. G. Wood, 74, Cheapside.

Within the space of some twenty-eight pages this booklet gives a number of practical hints that are likely to be of assistance to a beginner. The remainder of the work is devoted to a catalogue of the firm's stock of apparatus and chemicals.

The Photographic Record.

The July number of this publication, which is the (quarterly) organ of the Manchester Photographic Society, has a portrait of the Society's President, and besides useful papers on the *Carbon Process* (by W. T. Wilkinson), *Cresco-Fylma* (W. H. Shirley), *Gelatino-Chloride* (H. Wade), all read before the Society, includes some readable "general notes" and descriptions of "rambles," &c. The Question Box is an instructive feature.

We have received Fallowfield's *Remembrancer* for June and July. It is, as usual, an accurate record of the latest novelties.

Société des Amateurs Photographes (Paris) Annuaire Formulaire Illustré, 1891–92.

This tiny annual gives a history of the Society and, besides its rules and other matter of interest to members, a number of formulæ for development. It seems that even a photographic society abroad requires the authorisation of the Prefect of Police to exist. This is one of the things we manage better at home.

British Mosses.

By the Rt. Hon. Lord Justice Fry.

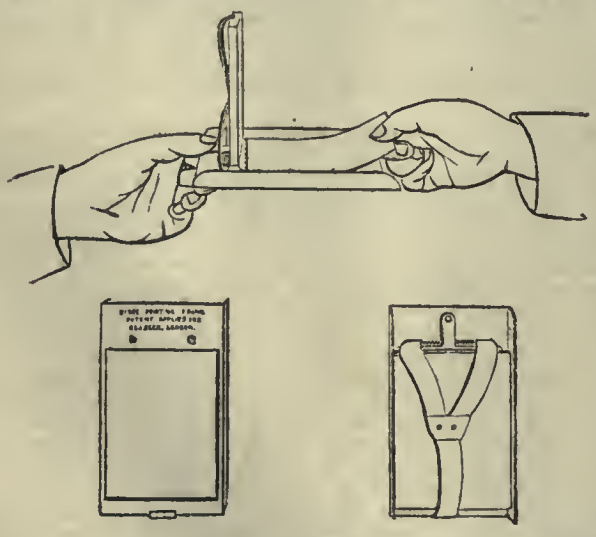
"Knowledge" Series. London: Witherby & Co., 326, High Holborn, W.C.

This is a painstaking study of British mosses, arising out of a lecture originally delivered at the Royal Institution in January 1891, the expanded papers thereon being reprinted from the pages of our contemporary *Knowledge*. The author deals with the classification, life history, modes of reproduction and organization of mosses, the chapters being admirably illustrated by Miss Agnes Fry. In a concluding note Sir Edward recommends the study of mosses to nature lovers, and winds up by a few simple directions as to how to begin that study.

The Bynoe Printing Frame.

London: R. & J. Beck, 69, Cornhill.

The advantages of being able to watch at one view the progress of printing, of ensuring optical contact however many times the print is



looked at, and of getting an even pressure over the whole surface of the print are only possessed in an imperfect degree by most printing frames. The neatly constructed piece of apparatus now before us is designed to secure these and other desiderata.

As may be gathered from the cut, the negative and sensitised paper upon being placed in position in the frame are gripped by a strong clip about the eighth of an inch from their ends, and are held firmly together, entirely independent of the pressure board at the back. This is said to give perfect freedom in the examination of the whole print, which remains immovably fixed until a small lever is pressed by the thumb. An even pressure is obtained by a hinged spring, which presses the centre of the back board and is automatically fastened down by a catch. The "Bynoe" printing frame embodies a clever idea, ingeniously executed, and possesses many claims to supersede the inefficient printing frame in common use.

The Photographer's Companion.

By Edward Dunmore.

London: Henry Greenwood & Co., 2 York-street, Covent Garden.

The sub-title of this work indicates that it is a collection of hints, expedients, and formulæ, systematically arranged as a supplementary reference book for use in the studio and dark room. In casting it on those lines, the author may congratulate himself upon having covered ground not hitherto invaded by photographic writers. The practical essentials and difficulties of most processes, ancient and modern, are fully, but not diffusely, discussed, and a good deal of serviceable information provided for those emergencies which are sure to arise in photographic procedure. The chapters on "Photographing Interiors," "Artificial Light," "Out-door Work," "Home Portraiture," "Copying," and "Composition Printing" are of particular value, but the entire work is of special interest to the practical photographer, and in that sense will, doubtless, be welcomed by both professionals and advanced amateurs alike. It is published in paper covers at 1*s.*, and in cloth at 1*s.* 6*d.*

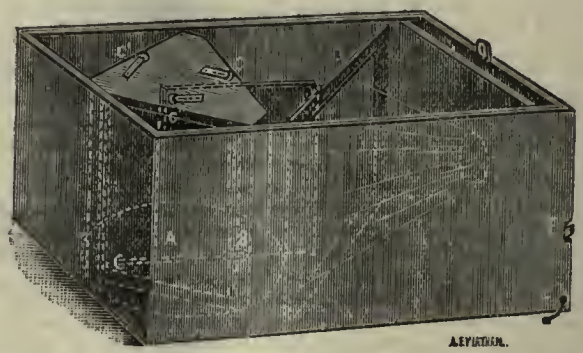
The "Surprise" Hand Camera.

Joseph Levi & Co., 40 Furnival-street, E.C.

There are certain features about the Surprise which entitle it to be regarded as a novelty, even in these days of ingenious hand cameras. It carries six plates or films, which are held in wooden carriers forming the three vertical sides of a revolving triangular prism, the carrier being double, thus holding a plate on each side.

The hand or arm A revolves the prism upon its axis, and brings in turn each side parallel to the front of the carrier.

After the front plate has been exposed, the hand B is turned round,



as shown by letter C, so as to bring to the front the plate No. 2, which was on the inner side of the camera. Care must be taken to always turn the lever A from right to left to ensure the proper and easy working of the apparatus. The same remarks apply to B. This mode of changing allows plates of various rapidity being used in the camera at the same time, and expose at will.

The back part of the camera is made absolutely light-tight by the mask, hinged on one side of the box and adjusting itself to each plate which is brought to the front for exposure. The price of the camera is 1*l.* 1*s.* It is cheap, novel, and ingenious.

The Strand Magazine for July.

London: George Newnes, Southampton-street.

The *Strand Magazine*, in its July number, in addition to a large assortment of exciting fiction, admirably illustrated, has instructive articles on "The Evolution of the Cycle" and "The Raising of the *Utopia*." The subject of Mr. Harry How's tactful interview is the prince of journalists, Mr. George Augustus Sala. The *Strand Magazine*, like the thoroughfare from which it derives its name, is always animated and interesting.

The Photographic Quarterly for July.

London: Hazell, Watson, & Viney, Creed-lane.

A seasonable illustrated article, by Mr. E. J. Humphreys, on "Life on the Broads," relieves by its chattiness the heavy, though excellent, bill of fare of the July number of the *Quarterly*. "Some Points on Exposure," by Mr. A. Watkins, and "A Recent Improvement in the Manufacture of Oxygen Gas," by Mr. Clement J. Leaper, are among the articles given.

RECENT PATENTS.

PATENT REPRINTED.

1890.

No. 13,631.—"Photographic Cameras." Ramsperger.

PATENTS COMPLETED.

Improvements in Frames for Photographs, Pictures, and the like.

No. 228. John Percy King and Henry William King, 222 and 224, Goswell-road, London.—*June* 11, 1892.

This invention relates to frames for pictures, photographs, and the like, and has for its object to provide improved means for introducing and removing photographs and the like into and from such frames.

According to our invention the frame is provided with a bezel, to which is hinged a lid forming the back of the frame, which lid is grooved or recessed to fit over the edges of the bezel to exclude dust. The hinge consists of a spring pin or bar attached to the lid, and having its two ends passed through holes in the bezel, and bent to form rings or eyes by means of which the frame can be suspended.

These holes through which the ends of the pin are passed are slightly out of the axial line of the pin, so that the normal tendency of the spring will be to retain the lid closed, the flexibility of the pin allowing the opening of the lid. The said spring-pin also serves to draw the said lid, so that a catch thereon engages with a notch or the like in the bezel.

At the back of the lid is a leg or strut for supporting the frame at an angle upon a table or the like. A spring is also placed inside the lid in such a manner that, when the lid is closed, the picture or the like will be held against the glass of the frame.

A Method or System by Means of which Pictures Projected upon a Screen from an Optical or Magic Lantern or Lanterns are Seen in Relief, or with Stereoscopic Effect.

No. 11,520. John Anderton, 142, Suffolk-street, Birmingham, Warwickshire.—*June* 18, 1892.

Two views or pictures of an object are taken in the direction in which it would be viewed by the two eyes, by photography or other means (as taken for the stereoscope), and these pictures are placed in an optical or magic lantern with two separate objectives, or in two or more separate lanterns.

Into the optical system of each objective or lantern is introduced a Nicol's prism, reflectors, plate of tourmaline, or any other material or apparatus that will polarise the light, and these for simplicity, say two Nicol's prisms, are so placed that the light will emerge from one lantern polarised in a plane at a right angle to that emerging from the other.

These two views so polarised are superposed upon a screen of ground glass, or any other material that will not depolarise or elliptically polarise the enlarged image or representation of the two views projected upon it.

The superposed views are viewed by the observer through a pair of analysers of Nicol's prisms or any other substance or system capable of effecting same, and these—say, Nicol's prisms—are placed with their planes of polarisation at right angles to each other. The one prism will permit the one picture that is polarised in the same plane to reach, say, the right eye, and will prevent the second picture from falling upon it; whilst the other prism, having its plane of polarisation at a right angle to the first, will permit the other picture, *i.e.*, the one that is polarised in the same plane, to reach the left eye, and will prevent the second picture from falling upon it.

There is then (as the pictures are already superposed upon the screen, and as upon each eye a different picture or view falls upon corresponding portions of the retina) all the conditions under which the effect of stereoscopic vision is produced, and therefore the combined picture appears in relief, giving the impression of actual solidity to the observer or observers.

By this method or system the colours of the pictures are not in any way affected.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I wish it to be understood that I do not limit myself to the more precise details herein set forth, as I may sometimes vary the same to suit different requirements, at the same time adhering to the main principle of this my invention. I declare that what I claim is:—The scientific arrangement of the several parts constituting an apparatus for giving, by polarisation, or partial polarisation of the light, a stereoscopic effect to pictures, and such like, projected upon a screen or elsewhere, and forming thereby a method or system by means of which such pictures or other objects being so projected from an optical or magic lantern or lanterns are seen in relief, substantially as herein more fully set forth and described.

Improvements Connected with Photographic Cameras and Stands.

No. 13,[illegible]. Archibald Campbell, Southwell House, Southwell-gardens, London, S.W.—*June* 18, 1892.

My invention consists of a photographic camera fixed to and forming the handle of a stick in the manner to be described, and forming a combination which may be used as a walking-stick. The axis of the lens is at right angles or nearly so, with the line of the stick, which bears on its end a conical pointed ferrule or spike by which it may be fixed in the ground.

The handle, containing lens and forming the camera, is of an egg shape (about the size and shape of a guillemot's egg), and is fixed on the stick near its smaller end. The "lens" slides in an "embracing tube" or cylindrical aperture in the smaller end of the handle in such a way that if pushed home (in focus for distant objects) the back of the lens will be vertically over the centre line of the stick, or nearly so. For focussing objects very close at hand the lens can be slid forward in its "embracing tube," distances being marked on the tube into which the lens or lenses are screwed ("lens tube"); so that if a mark, say, three feet, is just uncovered by the end of the "embracing tube," the lens will be "in focus" for objects at that distance from it. The lens can be slid right out of its "embracing tube" and used, in conjunction with a separate "enlarging apparatus," for producing enlarged positives from the negatives taken in the camera. The lens tube has a slot, through which diaphragms with various apertures may be inserted. In order to insert them the lens tube must be pulled half out of the embracing tube until this slot is uncovered. The diaphragms are made so as not to project outside the lens tube. A sensitive plate or film is placed at the larger end of the egg-shaped handle, the changing of plates or films being accomplished by hand, or by an automatic "changing box" or "roller slide." The method I prefer for changing plates (square, rectangular, or round) by hand is by means of a "changing bag" of some "light-tight," flexible material, having two apertures, the one to admit the larger end of the egg-shaped handle, and the other for the hand of the operator. The former aperture is made light-tight when the bag is in use by a stiff ring covered with velvet on its inside, and the latter by elastic bands closing round the operator's wrist. With this arrangement I make the larger end of the handle a removable cap, fitting on with a "bayonet joint," the plates being kept in a box within the changing bag.

The removal of the above cap and changing of plates is done by the hand of the operator inside the bag, the cap being replaced before the bag is taken off. The plate, when in position, rests with its four corners in notches cut in a projecting ring in the interior of the handle.

The handle is hollowed out to allow of the free passage of light from the lens to the sensitive surface, the "instantaneous shutter" (presently to be described), being supposed open. The smaller end of the egg-shaped handle consists of a removable cap covering the lens and fitted to the rest of the handle by a "bayonet joint."

A shutter with an "up and down" motion works in grooves immediately behind the back of the lens, and in a plane at right angles with the axes of the lens. These grooves extend a short distance down into the upper part of the stick, which upper part may be of metal tube such as brass, and of an internal diameter greater than the diameter of the back lens.

The up and down motion of the shutter is produced by a crank capable of being revolved by a spring. The shutter is connected to this crank, either directly or by an intermediate connecting rod.

The crank axle revolves on an axis parallel to the axis of the lens, its bearing being in a block fixed to the inside of the hollow upper portion of the stick. This block contains also, vertically above the bearing of the crank-axle (the stick being supposed vertical), the bearing of a catch, by which the shutter may be released (and the "exposure" made). The axles of both crank and catch project on the outside of the stick, a short distance under the larger end of the handle. The projection of the crank-axle bears a small button, by which the crank may be revolved by hand in a direction opposing the tension of the spring by which it is actuated, and so "winding up" the mechanism.

The catch directly releases the crank, and serves also to check its motion after one revolution. In order to effect this, it is made in the form of an ordinary clock escapement, with two short curved arms, one on each side of an axis, so that when one arm is on a level with the top of the crank, and about to release it, the other is below the crank, and in a position to intercept it. In the normal position of the catch, the latter arm stands clear of the crank, and the former intercepts it. This position is maintained by a spring. The projecting end of the catch-axle is bent round, so that an upward pressure of the finger raises the arm holding the crank, and releases it. The crank will then revolve, and the shutter will uncover and re-cover the back of the lens. If the finger be removed, and the pressure again applied, the crank will revolve once more. Each revolution will be slower than the last, until the actuating spring is slack, when the crank should stand in its lowest position, with the back of the lens exposed. This is the position in which "time exposures" are made, by means of the cap covering the front of the lens, which is kept uncovered during an "instantaneous" exposure. The actuating spring may be a spiral, with the inner end fixed directly to the crank-axle, and the outer to the bearing-block. Or it may consist of a straight helical spring, extending down a hole in the interior of the stick, and rotating the crank by a thread wound round a drum on the crank-axle. The end of the spring not attached to the thread may be fixed to the lower end of a rod, or stiff wire, fastened at its upper end to the bearing-block, and projecting down the centre of the spring.

The speed of the shutter is increased by "winding it up" (rotating the crank), or diminished by successive pressures on the catch. The whole mechanism of the "instantaneous shutter," described above (with the exception of the "vertical grooves"), is fixed to the "bearing block," and is thus easily detachable. The metal portion of the stick, to the interior of which the bearing block is fixed, screws or slides into a socket fixed to the lower part of the stick. (The upper hollow portion of the stick must be sufficiently large to allow of the free revolution of the crank.)

The "camera and shutter" may be detached from the socket and lower portion of the stick and fitted to some form of tripod stand, which may be constructed to fold up into the form resembling a stick.

But for ordinary use the spike (previously mentioned) will be found a sufficient support. As to material, I prefer to make the "handle" of the stick, as well as the actual shutter of the "instantaneous shutter" of ebonite. The stick may be of wood stained black, with an iron or steel spike., the upper or hollow portion of the stick, and the "embracing tube," "crank," "catch," and "lens-tube" of brass, bronzed black on the outside.

Having now particularly described and ascertained the nature of my inven-

tion, and in what manner the same is performed, I declare that what I claim is:—1. The combination of a photographic camera of small size with a stick in such a manner that the combination may be used as a walking-stick, substantially as herein described. 2. The combination of a photographic camera adapted for both "time" and instantaneous exposures" with a stick forming the stand thereof in such a manner that the combination may be used as a walking-stick, substantially as herein described. 3. The combination of a walking-stick having a pointed ferrule or spike with a photographic camera, and forming the stand thereof, substantially as herein described. 4. The improved instantaneous shutter and release-catch, substantially as herein described.

Improvements in the Manufacture of Colours, specially applicable for Colouring Photographs.

(A Communication by Carl Heinrich Wilhelm Bruns, Halberstadt, Germany.)

No. 3791. Alfred Julius Boult, 323, High Holborn, Middlesex.—*June* 18, 1892.

Although the colouring of photographs is both a lucrative and pleasant occupation, specially trained people only have hitherto been able to devote themselves to it, chiefly for the reason that there have been no colours exactly suitable for the purpose, either the ordinary oil colours or water colours having been resorted to. It is, however, a fact, that these colours do not, without difficulty, adhere to the surfaces of photographs which have been fixed, glazed with collodion, and generally treated for photographic purposes. It is therefore necessary to submit the colours to certain rather complicated preparatory operations—for example, to mix them with certain liquids, the nature of which is, in many cases, the secret of the individual artist performing the work. Besides, the colours hitherto used always entirely cover and conceal from view those delicate shades which form one of the peculiar advantages of photography, so that the general effect of the photograph, after colouring, is spoiled, as in no case is it possible to convert a photograph into a real oil painting. When coloured photographs have to be subsequently varnished with collodion, or otherwise glazed, it has generally been found that the colours were unfit for the reception of such varnish or glazing, and that the whole picture was spoiled in consequence.

The new colours obtained by the process, which forms the subject of this invention, enable photographs to be coloured without requiring any preparatory operation. The colouring of photographs is thus placed within reach of the general public, and is not confined to professional hands, and any lover of such work can colour a photograph in a few minutes. The original shades of the photograph are not only not concealed but rendered more prominent, and the resulting pictures present the appearance of a water-colour painting, which in colours is the nearest approach to photography, the glossy and yet somewhat dull colouring admirably suits the nature of a photograph. The colours adhere to any photographic surface whether or not treated with collodion, and if the picture be collodionised or glazed afterwards it is in no way damaged. These colours, which the inventor describes as "transparent glazing colours," are prepared in the following manner:—

Caseine, entirely freed from fatty substances (say, by means of the Soxhlets fat-extracting apparatus and by treatment with sulphuric ether), is allowed to dry for about twelve hours, during which time the ether that may have been left in it evaporates, and the caseine becomes fit for the subsequent treatment. In about 1250 grammes of water, on the other hand, 110 grammes of borax are dissolved. This solution is mixed with one kilogramme of the prepared caseine. Then, while the mixture is continually stirred, it is heated to the boiling point; but a moment before the boiling point is reached the stirring is discontinued, and the impurities rising to the surface are removed by means of a skimming ladle. After allowing the mass thus skimmed to boil a few minutes longer, it is cooled in a water bath.

The result is a liquid which, by being thoroughly mixed with the desired colouring matters, will produce colours for photographs such as have been above described, and which may, moreover, according to requirements, be mixed with or diluted in water without undergoing any alteration as regards their essential properties.

Having now particularly described and ascertained the nature of the said invention, and in what manner the same is to be performed, as communicated to me by my foreign correspondents, I declare that what I claim is:—1. The manufacture of colours suitable for colouring photographs, and capable of adhering to paper treated for photographic purposes, consisting in dissolving the colouring matters in, and mixing them with, caseine, boiled in water, with the addition of borax, substantially as described. 2. The herein-described manufacture of colour, suitable for colouring photographs, substantially as described.

Improvements in and connected with Stereoscopic and other Photographic Cameras.

No. 10,278. Etienne Ricard and Jean Baptist Joseph Lacroix, Agen, France.—*June* 18, 1892.

The present invention relates to a new and improved photographic camera which we prefer to term the "Velocigraph."

The camera has the peculiarity that, while it is in reality a magazine camera or a camera for a number of plates, it has no changing box or dark slide, or any distinct compartment for the plates, these latter being inserted directly into the camera in a vertical position and fall down horizontally and automatically on to the bottom of the camera after they have been exposed.

The apparatus is provided with a cap or cover in front which when closed protects the objective and the mechanism adjacent to it. The back of the camera is also provided with a second cover or cap to which is fixed or attached a strap which engages with a hook by means of a loop or buckle. The perfect closure of the front and back of the camera is ensured by pressing down the hook and so closing the lock to which it is connected.

The mechanism of the camera consists of a lever arm or handle for setting the shutter, a catch for liberating it, and an arm for regulating the velocity.

The shutter consists of two half shutters, or sectors of sheet metal, or other suitable material, each having a similar aperture, and both placed one upon the other and moving freely on the same pivot, which is further provided with a bent or curved rod, engaging with a part of one of the sectors, which is bent back upon the lower edge of the other sector. The result is that, when the setting handle is turned in one direction, the bent rod turns at the same time, carrying with it the sector with which said rod engages, and consequently also the other sector, the notched edge of which engages with a detent. The shutter having been in this way set without uncovering the objective, the setting handle is released and returns to its original position, owing to the action of a spring, as also does the bent rod.

To liberate the shutter, it is merely necessary to press upon the catch, which raises the detent and liberates or sets free one of the sectors, and permits the latter to be returned to its original position by a spring which, preferably, winds itself on a pulley keyed on to an axle. The aperture in one of the sectors passing in front of the objective allows the light for the instantaneous exposure to enter the camera.

One of the sectors is furnished with two notches in its edge. The first of these is for time exposures, that is to say, when it is held by a detent opposite the objective fully exposed. The second notch is for instantaneous exposures, as has been explained above.

The velocity of the shutter is regulated by moving the end of the before-mentioned arm along its graduated quadrant. This pointer is provided with a point; it is drawn forward a little and the point inserted in one of a series of holes in the graduated quadrant or plate. This operation having caused the pulley inside to rotate, a greater or less amount of tension is produced in the spring which is wound on said pulley.

The plates or films are first introduced into a dark slide of metal or other material, and are placed vertically in the back part of the chamber. They rest upon two blocks, and are constantly pressed forward by a spring-controlled rod. They are kept in position at their top part by a suitable anchor or stop with two teeth, the action of which will be described below.

To fill the apparatus the back end must be raised and the spring-controlled rod drawn back. For this purpose a pawl is caused to act as a brake by pressing upon its prolongation; this pawl then assumes a position in which it is retained by a spring which is in contact with a pin. The spring-controlled rod is then drawn back, and when it has arrived at the end of its course the pawl extension strikes against a tappet or stud which tips it up.

The whole arrangement remains of itself in the position it now occupies.

The apparatus having been filled, the spring-controlled rod is moved forward by hand, the pawl disengages with the tappet, and falls into the toothed sector.

Each plate is removed as soon as it has been exposed, the spring-controlled rod presses the plates forward until they have all been used, at which time further forward movement of the rod is prevented by a suitable stop.

The teeth of the sector serve as a break to prevent backward movement of the spring-controlled rod, and consequently of the packet of plates, when the camera is being worked.

The mechanism for changing the plates, forming the principal part of our invention, consists simply of an anchor very like that used in the escapement of a clock, and worked directly and simultaneously with the shutter by means of the lever arm. This anchor consists of an axle furnished at one end with a finger and at the other with two teeth, forming the anchor properly so called. When at rest, one of the teeth keeps the pile of plates in position, while the other tooth is sunk in the top wall of the camera. It is easy to see in what way the change of plates is effected. The first of the plates having been exposed, the apparatus is inclined slightly forward, and the shutter is set by means of the lever arm. The result of this movement is that a rod presses upon one of the fingers by means of its bent extremity, and in this way causes the axle to turn; the result is that one of the teeth is inserted between the first and the second plate, while the other tooth, sinking into the wall of the camera, allows the first plate to escape, which turns forward upon its base and, being guided by curved plates, falls upon the bottom of the camera.

When the shutter has been set, the setting arm is allowed to return to its original position, and one of the teeth rises, and the other tooth, taking up its original position, supports the plates, which are pressed against it by the spring rod, the axle on which the latter turns being provided with a toothed sector, which causes an indicator to turn, and enables the operator to see at any moment how many plates are still at his disposal.

To set the shutter without changing a plate, a case which necessarily occurs when the first plate after the filling of the camera is to be exposed, the setting arm is turned until the second notch in the shutter sector is engaged with by the detent, and it can easily be heard when this takes place, and the pointer is allowed to turn backwards. By this action, the anchor operating rod not having been moved sufficiently to let one of the teeth escape, none of the plates can fall.

To prevent the plates which have been exposed from moving about in the bottom of the camera when it is being carried, the setting arm is turned in the opposite direction; the prolongation of the bent rod on the shutter pivot then pushes a cushion which, being jointed, presses on the edges of the plates and keeps them in position between the cushion, which may be of thick soft leather, and blocks covered with soft leather.

Our system is equally applicable to stereoscopic cameras. Then the partition which divides the camera longitudinally into two equal portions is rendered movable to enable the plates to fall; this partition is soldered to the axle carrying the anchor or teeth in such a way that when the shutter is worked the said axle is caused to turn, the partition rises at the same time, and cannot prevent the plate that has been exposed from falling to the bottom of the chamber.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
July 18	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 18	Hastings and St. Leonards	
,, 18	Leeds (Technical)	Mechanics' Institute, Leeds.
,, 18	South London	Hanover Hall, Hanover-park, S.E.
,, 19	North London	Wellington Hall, Islington, N.
,, 19	Oxford Photo. Society	Society's Rooms, 136, High-street.
,, 19	Southport	Shaftesbury-buildings, Eastbank-st.
,, 20	Bury	Temperance Hall, Bury.
,, 20	Manchester Camera Club	Victoria Hotel, Manchester.
,, 20	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 20	Portsmouth	Y.M.C.A.-buildings, Landport.

,, 22	West London	Chiswick School of Art, Chiswick.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 7.—Mr. Alexander Mackie in the chair.

Mr. A. L. HENDERSON showed a small burnt-in enamel, produced by Mr. Spencer Cook, of Dunedin, New Zealand, who had succeeded simply with a few instructions by letter which Mr. Henderson had given him. Mr. Henderson considered the picture very promising, and observed that people said he did not give all the necessary information in the patent which he had taken out years ago. This was not the case.

ORTHOCHROMATIC PLATES AND HALATION.

Mr. W. P. DANDO had recently been using commercial isochromatic plates which gave halation, although backed with burnt sienna and caramel. He also observed that, in trying to reduce by means of methylated spirit and water, he found the films of the same plates dissolved away.

Mr. J. E. KELLOW also showed two negatives on isochromatic plates, both of which had been backed. One showed halation, the other did not.

Mr. F. W. PASK had used several of the same kind of plates, backed with sienna and caramel, without being troubled with halation.

CARAMEL BACKING.

Mr. DANDO asked the best method of backing plates for travelling? He found that caramel never absolutely dried.

Mr. A. HADDON suggested taking advantage of the tackiness of the caramel to cover it with paper.

Mr. A. E. DAWSON stated that caramel would dry in five minutes if properly made. As a rule, it was not boiled long enough. He had some made three months ago, which had not dried yet.

Mr. HADDON said that caramel, mixed with gelatine, produced an insoluble mixture, and subsequently stated that caramel should be made at a temperature of 220 Centigrade.

Mr. J. S. TEAPE, in reference to a complaint on the subject, said coating with a brush drawn in lines would leave portions of the caramel in ridges, to avoid which he recommended dabbing, or stippling the backing, on to the plate.

A PAPER DARK SLIDE.

Mr. HADDON observed that no doubt they had seen, in a penny photographic paper, an advertisement, running, "Why carry heavy wooden slides when twelve" (such as that which he exhibited) "could be made in an hour!" The specimen in question had cost him over a shilling; it consisted, apparently, of brown paper and cardboard, and Mr. Haddon said that he did not think any one would venture to expose plates in such a slide.

GELATINO-CHLORIDE IN 1885.

Mr. F. A. BRIDGE exhibited a photograph bearing date April, 1885, when Mr. Satchfield introduced his Acme gelatino-chloride paper. It was claimed that it printed in a third of the time of ordinary albumenised paper, but he (Mr. Bridge) found that it did not print so fast. The halves of the print were on Acme gelatino-chloride and ordinary albumenised paper respectively, and both were in good preservation.

INTENSIFICATION.

Mr. J. S. TEAPE, in the course of a short address on this subject, said that probably no member had done so little intensification as himself, as he always aimed to get density at the start. He had reason to believe that there was much less done now than in the past, and many things occurred to him which affected the matter in this direction. For one thing, they had exposure tables, actinographs, actinometers, &c., which enabled them to guard against excessive over-exposure, which, in the early gelatine days, was the cause of thin negatives. Slow and thickly coated plates for landscape work, which were in increased use, undoubtedly bore more exposure without giving a thin image than rapid plates. Backing, again, enabled a plate to stand more exposure without giving a thin image than an unbacked plate. The use of gelatino and collodio-chloride paper reduced the necessity for intensification, as they could obtain vigorous prints not otherwise got. Formerly the paper was prepared for the negative; but now such papers were ready for use. Captain Abney had said that, to get the greatest possible gradation in a negative, a thin image should be developed, and then intensified, and he (Mr. Teape) quite agreed with that. The range of tone was certainly greater in the negative developed right out in the first instance. The intensification of the half-tones to a greater extent than the high lights was a point of great value. A plate might be put into the solution, and the latter allowed to penetrate the half-tones only, the solution being prevented attacking the high lights, but it was a very difficult matter to reverse it—that is, to intensify the high lights more than the half-tones. He had tried Mr. Chapman Jones's method, but development went on so much that it could not be stopped, and he also found that a plate, intensified with uranium and washed for a quarter of an hour, had the density of the lights reduced, but the half-tones were untouched. It was difficult to say how that happened; but, as it touched upon the very point he had just mentioned, it was, perhaps, worth referring to. Possibly the dense parts of the image held the hypo more than the other parts of the film, and thus Farmer's reducer was formed, which might cause the reduction. Mr. Teape concluded by giving the following formulæ for intensifiers, which he had used himself:—

No. 1.

Potassium ferridcyanide	30 grains.
Uranium nitrate	30 ,,
Acetic acid	25 minims.
Water	10 ounces.

This might be used for a long time, and, when the action slowed, gave a red image. One of the advantages of the intensifier was that an excess of density could be removed by washing, or reduced, locally, by a dilute solution of carbonate of soda.

No. 2.—Monckhoven's Intensifier.

Solution 1.

Potassium bromide	10 grains.
Mercury bichloride	10 ,,
Water	1 ounce.

Solution 2.

Silver nitrate	10 grains.
Potassium cyanide	10 ,,
Water	10 ounces.

Solution No. 2 would give a precipitate, but a thirty-grain solution of cyanide should be added, drop by drop. Bleach and wash, and then apply the silver solution.

Mr. BRIDGE said that he never had occasion to intensify nowadays, and Mr. T. E. FRESHWATER made a similar remark.

Mr. TEAPE observed that, as very rapid plates only gave thin images, that supplied a special use for intensifying.

Mr. STEVENSON complained of pinholes with mercury, followed by ammonia.

Mr. C. H. COOK objected to mercury and ammonia, as the shadows were clogged up.

Mr. DANDO asked if it were not advisable to remove veil before intensification.

Mr. TEAPE said that was a very important point, and recommended bichromate of potash and sulphuric acid for the purpose.

Other members continued the discussion.

THE ZEISS ANASTIGMATS: SERIES II.

Mr. DANDO showed a Zeiss apochromatic Anastigmat (Series II.), which he said was the first one sent to this country. It had a focus of about six and three-quarter inches, and at *f*·6, the largest aperture, covered a whole-plate; at *f*·11 it covered a 10×8. The lens was intended for hand-camera work. The distance between the combinations was only three millimetres.

The meeting then closed.

North London Photographic Society.—July 5, 1892.—Mr. B. J. Grover in the chair.—Received with thanks, for library, Mr. E. Dunmore's *The Photographer's Companion*; Mr. J. Fallowfield's *Photographic Annual*. The Secretary reported that he had received a very kindly letter from Mr. J. Howson, of the Britannia Works Company, Ilford, who was to have addressed the meeting on *Isochromatic Photography*, stating that he had been called abroad, at a few hours' notice, on most urgent business, and would be unable to be present. The Company had, however, sent as a substitute a large parcel of their new isochromatic half-plates for distribution among the members, who, it was hoped, would test and report upon them. A vote of thanks was cordially passed to the Britannia Works Company for their liberal action in the matter. Notice of the change of programme had been sent to all members, and a general conversation on technical matters took place, principally on isochromatic plates. Mr. Brewer showed a successful negative of red roses taken on these plates, and the Secretary, who used hydroquinone (Ilford universal) as a developer, had found the isochromatic plates most useful. Other members preferred a pyro developer, but all who had tried agreed in the great advantage of the colour correction. The plates received were duly distributed as requested. Next meeting, July 19, *Holiday Outfits*.

North Middlesex Photographic Society.—July 11, Mr. C. C. Gill in the chair.—A technical evening was held. In the unavoidable absence of Mr. F. W. Cox, Mr. F. Cherry opened the discussion on *Development*. He dwelt chiefly upon the portraiture side of the question, gave his own method of working, and dealt with the allied subjects of lighting and exposure. Messrs. Beadle, Frost, Marchant, Smith, Taylor, Wall, Mattocks, Tittensor, and the Chairman took part in the discussion, which gradually tended in the direction of the prevention and cure of halation. The comparative difficulties and advantages connected with working celluloid films also attracted attention. Some of the members had found a difficulty in washing film negatives when a number had to be treated at once. Mr. Frost had solved the difficulty by bending the film into a cylindrical form, gelatine side inwards, and tying it round with a piece of thread. A number of them could then be put into a washing trough, and the water allowed to flow through them without fear of injury. They were then hung up to drain in the same state, and when dry the thread could be taken off. Three new members were elected. Prints were then shown on samples of the Eastman gelatino-chloride paper, which were distributed at the last meeting, the consensus of opinion being that the paper was good in all respects, and that widely different tones could be secured upon

it with certainty and ease. The usual competitions of views taken at field-days were held, the vote of merit being accorded to Mr. Marchant, for Broxbourne, and to Mr. Walker for South Mimms. The next meeting will be held on July 25, when Mr. F. Cherry will take the chair, and Mr. Thomas Bedding will addr as the Society. Visitors welcome.

Hackney Photographic Society.—July 5, Mr. Walter Barker in the chair.—The Chairman hoped the new quarters would be fully appreciated. A question from the box about whether carbonate of potash would frill more than ammonia was then discussed. Mr. Beckett had never had any frilling with either; possibly the temperature of the water was the cause. Mr. W. Fenton Jones said soft gelatine, used by some makers, was sometimes a cause. A question was then asked, "If two lenses of same focus were selected for use in stereoscopic work, would they be suitable, and would there be any difficulty of letting off shutters at same time?" Mr. Dando said there would be no mechanical difficulty, but the lenses ought to be good, and selected by an optician. Mr. Sodeau showed card on which 100, 200, and 300 parts of an inch were shown. Report of excursion was then taken, Mr. Gosling humorously describing it. Mr. Dean showed photograph of fungi eighteen and a half inches across; Mr. Barker, work done on Eastman gelatino-chloride paper, samples of which had been sent. Mr. Dando handed round a piece of the same paper which he had put in wrong way in frame, and asked, if he dissolved the gelatine from other side, would it fade? Mr. Beckett said, Not if paper had been properly fixed and washed. Mr. Gosling handed in prints on Ilford printing-out paper from negatives on Ilford isochromatic plates. Mr. Hudson showed an arrangement he had made—on the stereoscopic principle—for taking moving objects. The idea was, that focussing could be done on the top, and the exposure made immediately it was obtained sharply. Mr. Dando thought the top would rather draw out of focus. The Chairman showed a diaphragmatic shutter, the shutter opening from, and closing to, any sized diaphragm. It was said that the principle was wrong, as only fifty per cent. of exposure was obtained. Mr. Hensler had heard it stated that a smaller stop alters focus. The Chairman observed that Dallmeyer advocated focussing with any aperture *but* the full. Mr. Beckett said faulty lenses would alter in focus. The Chairman handed round a new hand camera of his own design. The plates dropped on to an indiarubber band, which one member declared was dangerous to the plates, as it would cause a formation of sulphur. Mr. Dando wanted to know whether storing backed plates would cause them to deteriorate, but an opinion was given that it did not. Mr. Dando was then unanimously chosen as a delegate to the Convention on behalf of the Society.

Leytonstone Camera Club.—The members of this Club had a most successful outing on July 2. The place of meeting was Kingston station. Some good shots were got in the town, it being market-day. The busy market was well patronised by carriers of hand cameras. The Coronation Stone and other historical spots having been visited, the party were ferried over the river, where points of vantage were secured for the bridge and town. The bridge was next crossed, and the party proceeded to the promenade, where some excellent snap-shots on the river were made. Proceeding along to Teddington, some good shutter exposures were made, the lock, going over the rollers, the weir, &c. The next outing is on July 16, to Cheshunt; meet Cheshunt station four o'clock. Visitors are heartily welcome.

Kensington and Bayswater Photographic Society.—July 11, Mr. F. A. Hahn in the chair.—Mr. G. W. Tottem, from Messrs. Houghton & Sons, gave a practical demonstration of their hand camera, the "Shuttle," and various other novelties. Mr. Winter, from Messrs. Mawson & Swan's, showed Loman's patent camera, a novel form of book camera, walking-stick tripod, &c.

Putney Photographic Society.—July 4, Rev. L. Macdona in the chair.—Messrs. Faulkner and Macdona gave a demonstration in development with rodinal and pyro-soda, showing how the results of a considerable over or under-exposure may be corrected by suitable modifications of the constituent parts of the developer. The demonstration was followed with much interest by the members present. Messrs. Faulkner and Zachariasen exhibited prints on the new Eastman chloride emulsion paper, which were greatly admired. Sample packets of the paper, presented by the Eastman Company, were distributed for trial amongst the members. Tylar's "Full-view" printing frame, an improved metal single dark slide, and other novelties were shown and discussed. Four new members were elected. The Society having joined the affiliation scheme of the Photographic Society of Great Britain, Messrs. Macdona, Vice-president, and Zachariasen, joint Hon. Secretary, were elected delegates to serve on the Central Committee of the affiliated societies. The summer outings, held on alternate Saturdays, to places in the neighbourhood, have been very successful; many good negatives have been taken, and will, no doubt, give additional interest to the competition amongst members for the Society's medals. The outings have been particularly instructive to the beginners who have been able to profit by the kind assistance given them by the more proficient. The next outing will be held on Saturday, July 23, at three p.m., at Hampton Court.

South London Photographic Society.—July 4, 1892, the President (Mr. F. W. Edwards) in the chair. Attendance 33.—Mr. J. F. Kelly read a paper, *Can our Excursions be made more Interesting and Useful?* After a brief description of a typical photographic excursion, the lecturer dealt with a large number of suggestions for rendering such meetings more attractive and useful. He considered that excursions should always be arranged to suit the pockets of the majority of the members, and suggested that, at the commencement of each excursion, a short demonstration by some competent member, nominated for the purpose, of the practical use of some part of our apparatus in the field, as the proper use of the rising front and the swing, the capabilities of lenses, exposure, and the uses of tables and meters, shutters, &c. He regarded excursions as a means of educating the younger and inexperienced members of the Society, while the more competent workers would use them as prospecting times for more serious work. The announcement at the preceding meeting of the places to be photographed, and the points of interest, &c., would be useful. The social side was dealt with. The lecturer urged that excursions should be arranged with some end in view, as, for instance, the illustration of the river Thames from Sheerness to Oxford, a complete series of social views, the monuments of London, &c. Results should be shown at the following Society meeting, and a free and impartial criticism indulged in, and advice and suggestions given. Mr. Kelly deprecated the practice of stowing away good negatives until the exhibition, for fear that some brother worker might infringe his copyright—the view was not made by the first man, that is common property, and the second might not be able to so arrange it as to make a picture, or might make a better; then, if so, he deserved the credit of it. A set of good lantern slides, illustrating the excursion, should be made yearly, to become the property of the club, and loaned to members after they have been exhibited at a meeting to be held for the purpose. This meeting might be so arranged as to form a general entertainment by the members, and be productive of general good feelings. Mr. Kelly's remarks were criticised to great length by the members present.

Lewes Photographic Society.—July 5.—A small exhibition of hand cameras was held. Some of the members described the cameras they had in use, and Mr. E. J. Bedford gave a description of several of the latest patterns, which had kindly been lent by Mr. Hardcastle, of Brighton. The certificate for the last quarterly competition, for "the best photograph of animal life," was awarded to Mr. J. Tunks. Mr. Foxall (Brighton) judged the prints sent in, which were not so numerous as might be desired. The Society will make an excursion to Alfriston on Saturday, if the weather is favourable. Others have been arranged for Buxted, Newick, and Isfield. The subject for next quarterly competition is "Landscape, with or without figures." Mr. J. L. Adam was elected a member of the Society.

Sheffield Photographic Society.—July 5.—Mr. B. J. Taylor in the chair. After the election of two new members, Mr. C. W. Crowder gave a paper on *A Holiday Tour on the Norfolk Broads.* He began by describing the journey to Yarmouth, and from thence to various resorts on the Broads; also the best and most convenient means to get there. The Secretary laid upon the table samples of the new Eastman printing paper, and intimated that the excursion to Allport next Wednesday gives promise of a large number taking part in it.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

HELIOCHROMY.

To the EDITOR.

SIR,—I cannot find any excuse for Dr. Vogel's persistent misrepresentation of facts. He may have such a bad memory that he forgets important occurrences after a few years, and he may not understand the English language well enough to have learned that the heliochromoscope is not a projecting lantern; but I doubt it. I had positive assurance that Dr. Vogel received and replied to the statement, which he now says he never received. Any one who will look may see that he did not "acknowledge" the heliochromoscope on page 318, as he has twice positively asserted that he did. I believe that every statement made in my last letter was strictly true. I know that Dr. Vogel's alleged principle cannot be carried out in accordance with the Young-Helmholtz theory of colour vision. I do not know that Dr. Vogel has ever produced any good results by any photo-chromic process. My position is clearly defined in the paper recently reprinted in your JOURNAL, page 357. I believe that the repeated misrepresentations which my references have proved are quite sufficient to justify me in declining to have any further controversy with Dr. Vogel.—I am, yours, &c.,

F. E. IVES.

London, July 8, 1892.

SPEED OF PLATES.

To the EDITOR.

SIR,—Allow me to thank Mr. Watkins for his considerate reply to my letter of the 10th ult. There seems to be but little difference in our views needing comment, at any rate, except as to the method suggested of using Spurge's sensitometer and a standard tint-plate. This instrument gives a series of exposures, increasing in geometrical progression, the amount doubling at every third hole. Thus, counting from the smallest hole, the holes 1, 4, 7, 10, &c., constantly double the exposure. It is required to compare the speed of two plates by means of this instrument.

The plates are exposed behind the sensitometer to the same illumination developed for (say) twenty minutes, fixed and dried. On comparison with a standard tint, one plate, A, is found to possess that tint with exposure No. 7, the second with exposure No. 10. It is inferred that, as exposure No. 10 is double of No. 7, the first plate is twice as rapid as the second. We are here judging from an examination of one tint only of each plate, and that is what I called "restricted observation."

If we examine *all* the tints, and find that tint 8 of plate A agrees with tint 11 of B; 9 of A with 12 of B, and so on throughout, then undoubtedly the first plate is twice as rapid as the second; but it is just here that I apprehend that the method would fail, it is generally the case that other tints, say, 9 and 13, would agree, and had *that* tint been adopted as the standard (and it is arbitrary) a different speed would have resulted.

If, instead of confining our observations to one tint, we note the behaviour of the tints among themselves, we get a much more definite result; Messrs. Hurter & Driffield would say: "If in plate A the densities

increase with approximately equal increments from and beginning with No. 7, and those of plate B from No. 10, then, no matter how the densities of one plate compare with those of the other, A is twice as fast as B." The first few exposures never increase in density in this regular manner, nor do excessive exposures, but there is always a range that does increase thus regularly; find the first term of this regular series, and the problem is solved.

There now arises the question, *how much* light has fallen through hole No. 7 or hole No. 10. If this can be answered, we need not refer one plate to another as a standard, but express the rapidity in terms of the light itself. Failing a better unit, the authors of the method use the standard candle at a metre distance, and say that the *inertia* of a plate, *i.e.*, the amount of illumination needful to bring the plate to the commencement of the regular series of densities, is so many candle-metre seconds.

The next step is, I think, not generally known. It is, however, important as answering, *in a great degree*, the objection that the speed has been determined by artificial, not natural, light. Just as Mr. Watkins, by actual camera trial, finds the plate number on his meter for a given plate to be 51, so by actual trial Messrs. Hurter & Driffield find the actinograph number to be 34 *when the inertia is* 1 *C. M. S.* Therefore, for any plate, they divide 34 by the inertia to obtain the actinograph speed. The assumption is that, if one plate is twice as rapid as another to candle-light, so it is to daylight. It is a natural assumption, and is justified by the success of the actinograph to indicate the correct exposure on the strength of this assumption.

As Mr. Watkins states that he is engaged with the investigation of this subject, and that for this reason he defers giving his views in a complete form, it would be unreasonable to expect a detailed argument from him. The subject, however, being of wide interest, it may not be out of place for me to bring before your readers the complicated nature of the problem, and the remarkable researches which have been brought to bear on its solution.—I am, yours, &c., R. C. Phillips.

The Arts Club, Manchester, July 4, 1892.

P.S. I have before me the records of two plates, both highly developed. An exposure of 0·625 C.M.S. on one gives the same density as 1·3 on the other; 2·5 on the one gives the same as 5·6 on the other; and 21 C. M. S. gives the same density in both cases. What could be concluded from these *data* as to the relative speed of the plates? The speeds are actually as 54 : 20.

CLEAN NEGATIVES.

To the Editor.

Sir,—I find the best and simplest way of removing the green or iridescent stain on the negative is by gently rubbing the surface with a tuft of cotton-wool moistened with spirit, or it can be done directly after fixing by rubbing with the finger; but, of course, it requires more care than with the spirit when the negative is dry. I see a correspondent complains about the new platinotype paper. I enclose a piece, mottled; the cause was being left by accident in contact in the printing frame with a negative which was very dense, being over-intensified with mercury.—I am yours, &c., T. W. Kirby.

22, *Grove-park, Liverpool, July* 11, 1892.

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editor.

Sir,—We will only trouble you with a very short reply to the letters of Messrs. Allison Bros. and Mr. Acworth, which appeared in last week's Journal. The letter of Messrs. Allison Bros. fully corroborates our statement as to the disclaiming clause which, by order of the Comptroller, was inserted in Dr. Vogel's specification (No. 15,532, 1886) in consequence of our opposition. As to the legal effect of the disclaimer, Messrs. Allison, as patent agents, have a perfect right to their opinion; on the other side, we have the opinion of the most eminent patent law counsel that the effect would be as we have stated, "that the Vogel process could only be worked in this country under the Tailfer patent." We have, therefore, good reason for considering our opposition as successful.

Our description of Dr. Vogel's system of "optical sensitising" by means of dyes was taken from his own English specification, No. 7963, dated June 15, 1886. In this specification, although many dyes are mentioned, not a word is said about eosine, the superior properties of which as a colour sensitiser for gelatino-bromide of silver would appear only to have been recognised by the Professor at a later date, the specification of his so-called "eoside of silver" process being dated November 29 of the same year. As to this latter process, we deny entirely Dr. Vogel's right to claim it; we maintain that it is simply a copy of the Tailfer process; in fact, only a more roundabout way of producing by the same means, *i.e.*, eosine and ammonia, precisely the same colour sensitive compound of eosinated bromide of silver which is obtained more directly by Tailfer's method.

We have additional evidence to this effect in Dr. Acworth's own letter of last week, in which he says that in our isochromatic plates, which are made by the Tailfer process, "the dye is present, combined with silver as recommended in Professor Vogel's patent." Precisely so, the result is exactly the same, except that plates prepared as recommended in Dr. Vogel's patent will not keep, as Dr. Acworth has already admitted in his paper read before the Photographic Society.

We do not intend to discuss the validity of Tailfer's patent. If further evidence is required on that point, it will be found in the disclaimer published at the end of Dr. Vogel's specification. We are perfectly satisfied ourselves, and with our licensees, the Britannia Works Company, Ilford, are fully prepared to maintain our rights by all legal means.

With M. Vidal's spiteful letters to Dr. Acworth we have nothing whatever to do. It only concerns M. Tailfer, who will doubtless know how to deal with its author and publisher.—I am, yours, &c.,

Hackney, July 12, 1892. B. J. Edwards & Co.

CORRECT EXPOSURE.

To the Editor.

Sir,—It is difficult to believe that Messrs. E. Collier Green and John Sterry fancy that the focal length of a lens is not one of the factors regulating the intensity of the illumination of the plate during exposure, yet that is what their letters in your issue of July 8 seem to imply.

Mr. Green says: "Now, in the case of two lenses, one double the focal length of the other, and both having the same relative stop, the number of rays of light from any unit of surface of the landscape which pass through the stops will, in the case of the longer-focus lens, be four times greater than in the case of the shorter-focus one, *for the area of the stop is as four to one.*"

According to Mr. Green, therefore, with two lenses, one of eight-inch focus and one of four-inch focus, used with an identical stop of one inch in diameter, the effect on the plate will be the same in both cases, for, to use his words, only altered so as to apply to this case, the number of rays of light from any unit of surface of the landscape which pass through the stop will, in the case of both lenses, be the same, for the area of the stop is the same. As a matter of fact, however, the ratio of intensity of the two lenses used under these conditions is as one to four; in other words, the plate is four times as brilliantly lighted by the four-inch focus lens as when the eight-inch focus lens is used.

Mr. John Sterry, too, seems to think that the distance of the plate from the stop which regulates the amount of light is a negligeable factor, for he says: "Surely it is evident that when the plate is placed at half the original distance (which fact I had by no means forgotten), where the *same* amount of light covers the *same* area of plate, the illumination must be equal."

If by that he means the same amount of light at the point where the plate is, the statement is correct; but this is not what he said in his letter in your issue of June 24. The important words of his then were: "The stop has been reduced to a quarter of the area, and allows exactly the same amount of light to pass as before."

If, therefore, his statement is meant to imply that where the same amount of light admitted by the stop illuminates the same area of plate the illumination must be equal, it is by no means true; for, as is pointed out above, the distance of the plate from the stop is as important a factor in regulating the intensity of illumination as the size of the stop itself.—I am, yours, &c., M. J. Michael.

July 12, 1892.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange Dallmeyer's 2 B for 3 D or Ross Universal.—A. Jennings, 85, St. Alban's View, Blackburn

Exchange, wanted good posing chair, two or three backs, and table, exchange 48-key English concertina by Wheatstone.—Address, Treegow, photographer, Whittlesea.

Will exchange splendid French rapid rectilinear lens, whole plate, ten-inch focus, for wide-angle rectilinear or outside show cases.—Address, Wilkinson, Church-green, Harpenden, Herts.

Samuel's patent hand camera with two finders, rapid rectilinear lens, holds twelve quarters, in exchange for 10×8 view lens or 9×7 rapid rectilinear.—Address, J. Dunn, 1 Laygate-place, South Shields.

Exchange quarter-plate instantograph set (brass bound) with three double brass bound slide lens shutter, tripod and sling case for good half-plate set with cash.—W. Anderson, Polvellon, Yelverton, South Devon, R.S.O.

Will exchange No. 4 junior Kodak little used, or 12×10 modern tourist camera, three double slides and tripod, or 12×10 rapid rectilinear, and 12×10 wide-angle rectilinear, for a 10×8 Ross universal symmetrical lens.—Address, E. W. Mellor, Fairlawn, Lytham.

Exchange Coiffier's full-plate lens; *Photography*, Vol. III. complete; The British Journal of Photography, 1890-91; *Photography*, Vol. LXXXIII. to XCI.; for good second-hand half-plate camera, double slides, latest improvements by a good maker.—Address, A. Clarke, Art Studio, Bethesda.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

Goodwin Thorley, Long Eaton.—*Photograph of Sir Walter Foster, M.P., head and shoulders. Also one showing head, shoulders, and the arms crossed in front.*

E. MATTHEWS.—No.

MIA.—Received; in our next.

FAIR PLAY.—Better communicate with the Company on the subject.

FIDES.—We do not think you would be justified in doubting the integrity of the person referred to.

T. C.—Common German moulding is not worth renovating. New frames will be by far the cheapest.

C. BUNYARD.—The plan you propose appears suitable, seeing that the length of the room is not available.

E. LIESEGANG (Düsseldorf.)—The *Idler* is published by Messrs. Chatto & Windus, Piccadilly, London, W.

ETHEL CONSTANCE MAY.—The phrase you refer to was inserted by inadvertence. Thanks for calling our attention to the matter.

BULLOCK BROTHERS (Macclesfield).—Messrs. Waterlow, the London Stereoscopic Company, and other firms undertake most, if not all, photo-mechanical processes.

JAS. NOWELL.—For particulars of the forthcoming exhibition of the Photographic Society of Great Britain address the Assistaut Secretary, 50, Great Russell-street, W.C.

LITTLE and MCCLEAN.—The picture is probably a collotype, such work, of which it is an example, being, we believe, undertaken by the London Stereoscopic Company and other firms.

A. M. W. asks us for a design for a good detective camera that is free from patents. Several have been described in back volumes, but most of them have since formed, wholly or in part, the subject of patents.

F. SHORT says: "I have a Daguerreotype for copying, and unfortunately it has been scratched badly. Is there any means of getting rid of the scratches?"—We know of no means of removing the scratches.

T. MCALPINE.—See article in the present number. In that you will find your difficulty dealt with, and from it you will be able to see the cause of your trouble better than we can point it out from the limited details contained in your letter.

R. S. A.—Build the studio as shown in the plan, as eighteen feet would be too short for general work if built the other way. As, from the description, we imagine no light will be obtained from the west side, the studio had better be constructed on the "lean-to" principle.

CLARINA HILL.—If space is available, erect the studio so that it runs from north to south. Twenty feet will be very short for anything but bust or three-quarter figures. As regards the cost, you had better get a builder in your neighbourhood to give an estimate for the work.

OTHELLO.—We are not aware of any such contrivance. Probably the best arrangement for you would be a double camera, with the foci of the lenses equal. This would enable you to observe the image on the ground glass of the upper camera without the necessity of taking out the slide.

W. J. BEDWELL says that in the formula given for matt varnish there are no directions for use, and asks if it is to be used like ordinary varnish—the plate warmed and the varnish flowed over—or should it be applied to the negative cold?—The varnish should be used without heating the plate.

J. M. P. says he has a portrait lens three and a quarter inches in diameter, and ten inch focus, and a rapid rectilinear of about half that diameter, and twelve inches focus, and wants to know which lens would be the better for copying some pictures twelve inches long, on 10×8 plates?—The latter lens will be the better to use.

ALF. C. WARD.—The "dull, or ground-glass appearance" of negatives and transparencies developed with the ferrous oxalate developer is due to the lime in the washing water, which causes a precipitate of oxalate of lime on the film. Very dilute hydrochloric acid will dissolve it, and make the picture transparent again.

REV. C. A. asks if there is a copyright still existiug in the old Bartolozzi prints—those printed in a red or sepia ink?—The copyright in Bartolozzi's original works has expired. Many of the prints have been reproduced, and it is possible that there may be a copyright in some of the reproductions, though in the original prints there is none.

G. H.—1. With care, the prints need not be creased or torn in drawing them over a flat piece of wood to prevent them from curling. Commercial prints, that are put into the market unmounted, are usually rolled, under heavy pressure, on a burnished steel plate. They then keep flat, and have a high gloss, which they retain. 2. Try the flash light; it is inexpensive.

OXFORD.—We believe you are legally in the wrong in exhibiting the picture, but, outside the question of legal rights, we should advise you, as the lady objects to its exhibition, and simply, as an act of policy, to defer to her wishes. She may be of "little moment" in your town, but it is not wise to provoke a conflict which can do ou no ood, if even it does not do you harm.

P. O. Q.—If the youth is not being taught the trade, and is merely employed at menial work, our advice is, Consult your solicitor. He will, no doubt, find the indentures are valid, advise you to commence an action for the return of the premium you have paid, together with damages for loss of time, and something for services rendered. Your complaint is not altogether an unusual one.

ELECTOR.—The prints are over-toned. Although they may have been taken out of the bath while they were quite brown, they are still over-toned. They are mealy, which would not have been the case had they been removed at an earlier stage. Some papers, particularly when the negatives are not very vigorous, will not stand toning beyond the red stage without becoming mealy, although they will yield good prints of that tone.

C. BENNETT (Lymington).—From the appearance of the negative, we should judge that the water contains some impurity, such as iron, particles of which are impressed in the soft film by the sponge. Each of the spots has a distinct nucleus. Under the circumstances, you had better abandon the use of the sponge. We fear the spots are irremovable, but you might try the effect of reducing the negative down to a very thin image, and then intensifying it.

C. HOOD asks how he can take stereoscopic views of street scenes—instantaneous pictures—with a single camera. The thing is easy if the camera is large enough to take a half-plate. Then all that is necessary is to fit a partition in the centre of the camera, so as to divide it into two parts, and screw a pair of stereoscopic lenses on the front. If the camera is not large enough for this, the thing is impossible, so far as instantaneous views of moving objects are concerned.

H. S. says: "Enclosed is a sample of a quantity of prints I have had brought to me to take off mounts and remount in album. After they were unmounted, and as they dried, they came up like the print enclosed. Could you kindly inform me what will restore them to their original state?"—The print sent is a collotype that has been varnished with an aqueous solution of lac. Clean off the "chilled" varnish with methylated spirit, and then re-varnish with an aqueous solution of white lac in borax. That will restore the prints to their original state.

OPALINE says: "I have mounted some photographs on bevelled glasses as opalines and am about to fasten the backs or stands on. Is it safe to use ordinary glue for that purpose directly on back of photographs? If not perhaps you can kindly suggest the best method. If you can tell me a good means of spotting such prints so that the colour will not come off in wetting I shall be glad.—1. In place of glue we should recommend you to employ gelatine—the best kind to use is Nelson's soup gelatine. 2. Ordinary artist's oil colours with rectified spirit of turpentine.

REDNEB.—Burton's book on *Photographic Printing Processes* (Marion & Co.) will give you a general idea of the different mechanical processes, and from that you will be able to form an estimate of the cost of plant, according to the scale you wish to commence upon. The plant of some of the most successful commercial workers cost many thousands of pounds. With suitable machinery and appliances, we see no reason why you should not compete successfully with large firms, if you do the same or better work. Portraiture is not so profitable now as it was years ago.

PHOTOGRAPHIC CLUB.—July 20, *Photo-mechanical Processes.* 27, Report of the Delegates to the Convention. 16, Outing to Watford.

WE note that Mr. F. A. Bridge is announced to give a lecture on "Quaint and Humorous Songs" at the Birkbeck Institute on Wednesday next.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—July 21, Adjourned Discussion—*Intensification.* 28, Delegates' Report of the Edinburgh Convention.

SINGAPORE PHOTOGRAPHIC EXHIBITION.—The Exhibition of the Singapore Amateur Photographic Society opened on June 3 last. Some of the pictures are admirable specimens of art, and will bear comparison with the results of professional photographers. Looking first at the competition pictures, the prize for the best set of landscapes was taken by Mr. H. M. Simons. The second best set of landscapes were sent in by the Hon. Secretary, Mr. E. J. Robertson, an avenue of the Botanical Gardens at Buitenzorg being the pick of the three. A group of the students at the Malay College was reproduced in the *Daily Graphic*, and the two prints are exhibited in juxtaposition. The best work of the whole exhibition is to be found on Mr. D. C. Neave's stands. Two beautiful prints of lilies and a transparency are of the highest merit, artistic in design and technically almost perfect. A splendid interior is also shown by Mr. Neave, who also has a small table showing details of a photo-mechanical process for the production of plates for newspapers and illustrations. The original, the negatives, the zinc positive, etched plate, and final picture of this complicated process are to be seen. On an adjacent table, Mr. Heim shows some good stereoscopic slides. Mr. W. Thomson shows a series of good pictures, some of his interiors being most successful. "G." has some good prints of the native troops at Blakang Mati and the "R.E." of Saigon. The list of things worth looking at is by no means exhausted. There is some weak, slipshod work, but the wonder is not that such should appear, but that a Society of so small dimensions numerically should be able to show so much as the results of a year's work. The members are heartily to be congratulated.

JOURNAL OF PHOTOGRAPHY.

No. 1681. Vol. XXXIX.—JULY 22, 1892.

DO NEGATIVES LOSE DENSITY IN FIXING?

It may be remembered that some months ago an esteemed correspondent, Mr. Albert Levy, of Paris, favoured us with a communication, in which he implied that the density of a developed gelatine negative suffered reduction in the hypo fixing bath. Applied in this connexion, the term "reduction of density" would, in its ordinary acceptation, be held to have a purely comparative meaning, since it must be obvious that, in gauging the density of an unfixed negative by the artificial illumination of the dark room, the influence of a substratum of unaltered salt in the plate converts the point into one of individual judgment, which, as the resulting negative too often shows, is as liable to be fallacious as not. There is no respect, indeed, in which both beginner and proficient are so likely to trip as in deciding when the negative has reached proper printing density, to which circumstance we are inclined to trace a not infrequent necessity for an intensification or strengthening of the image, which is often ascribed to other causes.

The burden of our correspondent's contention, however, was, not that there was an apparent reduction due to an optical deception, but that in reality the actual density of the developed image underwent diminution in the fixing bath, and we therefore endeavoured to demolish the theory that any reduction took place, supporting our argument by such evidence to the contrary as instantly appeals to the mind when the feasibility of the phenomenon is briefly considered. Our conclusion was that the loss in question might be due either to under-development or under-exposure, or both in combination, the apparent density of the image being influenced to a great extent by the colour or consistency of the original film.

We observe that the subject of this assumed loss of density came under discussion at a recent meeting at one of the London photographic societies, and, from what was said on the occasion in question, we are induced to suppose that there is a more or less general belief that a real reduction of developed density does take place in the fixing bath.

On practical as well as theoretical grounds we have no hesitation in meeting the proposition in a spirit of scepticism. We say now, as we said before, that in imputing this reducing property to the fixing bath the latter is assumed to have the power, at a normal strength and for a normal time, of dissolving out the metallic silver of a developed gelatine negative to a material extent. Such a conclusion has, to our knowledge, never been practically demonstrated or maintained.

But why is this reduction of density assumed to be confined to the negative? If it takes place in that case, are not lantern slides and transparencies equally liable to loss? What, too, of developed gelatino-bromide prints, of printed-out emulsion papers? If density of deposit—not mere apparent density, mind, which is another thing, and not, of course, what is meant—is reduced in negatives by the fixing bath, it is equally at the mercy of hypo in the other cases we have cited; but, so far, we are without any data to warrant the assumption that it has ever been noticed or experienced.

Confining ourselves to the question of negatives, however, the conclusion forced upon us from a consideration of the point is, that whatever reduction takes place is apparent and not real. On the previous occasion we drew attention to the circumstance that the presence of iodide in the film renders it more opaque, so that it is easy to conceive how, in development, a backing of bromo-iodide of silver, being presumably of a deeper colour than pure bromide, would conduce to an appearance of greater density of the image than where the sensitive compound was confined to the latter salt alone. We have hinted advisedly that silver bromo-iodide is only presumably yellow, as compared with pure bromide alone; for it is, we believe, known to experimentalists and others that the latter salt occasionally assumes, in an emulsion, a yellowish tinge, which renders it indistinguishable, even to the experienced eye, from silver iodide.

Other causes, in addition to the foregoing, may lead the incautious to generalise too hastily over this supposed evanishment of developed density. Among these we select inconstancy or irregularity of dark-room illumination. If the light be comparatively weak, either from the employment of a small flame or too dark a tint of non-actinic material, the density of a negative is liable to be over-estimated, especially if the operator is usually, or even occasionally, accustomed to work by a less subdued light. Over-exposure is an obvious trap in mistaking density, especially in a weak light, and, coming from the general to the particular, different makes and rapidities of plates vary so greatly, both in colour as well as thickness of coating, that, even where one is working by an invariable illuminant, the imagination is easily seduced into an erroneous comparative estimation of density. This leads us here briefly to lay stress on the value of uniformity of dark-room illumination on the score indicated, as well as on that of others.

A discoloured developer is by no means a negligeable factor in the creation of false impressions as to density, and another thing which facilitates, although, of course, only slightly, the optical deception is the fact that the film is wet. In point of fact, a wet negative appears denser than a dry one. But the main cause of the illusion is, of course, the colourific property of the unaltered salt. On the last occasion when we treated of this interesting point, we remember fixing the half of a negative (leaving the other half unfixed) that had been taken on a slow plate, which we knew contained a compara-

tively large quantity of iodide. Upon examining the plate by ruby light, the difference in apparent density was enormous, and the same disparity was maintained against a naked gas flame.

But the example we cite was one of apparent reduction only, and under that head, we are convinced, come all those cases where loss of density is complained of. No such loss, we submit, actually takes place—unless, perchance, we have all along existed in dark ignorance as to the action of alkaline developers on the exposed silver haloids in gelatine, and have deprived dilute hypo of a right to be considered, with nitric acid, a solvent of metallic silver.

PLATINUM AND PLATINUM RESIDUES.

New developments of probably the most stable of all photographic printing processes naturally lead to the dissemination of an increased amount of interest as to the available sources of supply of metallic platinum, and, in response to a suggestion recently made to us with that object, we here indicate the region from which, notwithstanding the frequent reports alleging the discovery of platinum in Australia and other parts of the globe, the supply of the metal for the various uses to which it is now placed is principally derived.

The platinum beds of the Ural Mountains, according to a foreign contemporary, are the only ones in the world in which the metal is found in grains. Platinum is found in Brazil and in the Cordilleras in the hard serpentine rocks, but never in the form of grains. The platinum beds of the Ural Mountains are found in various districts. The platinum found in these places is in the form of grains, in sand frequently containing gold. The weight of the grains is from 17 to 21 grammes to every 1640 kilogrammes of sand. The richness of the platinum beds varies in the same proportions. In some, the thickness of the turf covering the sand does not exceed from 2·16 metres to 2·88 metres; while in others it varies from 10·80 metres to 14 metres, so that it becomes necessary to work underground. The thickness of the platinum sands does not vary much. A noticeable characteristic of it is that they are found in the form of friable grit, and easily washable. The clayey sand is rarely met with.

The demand for platinum for industrial purposes is relatively restricted, as it only dates from the last twelve or fifteen years. It is, of course, as our readers are aware, largely used for electric lighting and dynamo conductors, and considerable quantities of it are employed for photographic and chemical purposes generally. During the last twelve years the annual production of platinum has averaged about 3194 kilogrammes, of which half has been derived from the beds in the north of the Ural Mountains, belonging either to the State or to private persons.

Throughout the whole world only about 3270 kilogrammes of platinum are annually used; but it is anticipated that this amount will soon be considerably increased, and it is stated that the platinum beds of Bisserski can alone supply the total quantity required for the consumption of the world. When the demand for platinum was insignificant and the price very low, the gold miners who found platinum while seeking gold frequently, it is stated, used the former, instead of lead, as shot for firing at wild birds.

Although the consumption of platinum in photography is small compared with the extent to which it is used in other arts and industries, its characteristic fluctuations in price give it something more than a sentimental interest to photographers, who on at least one occasion have had cause to deplore its temporary scarcity by an increased price of the salt employed in the production of the platinum image.

Where a large quantity of platinum paper is used, it is apparent that great importance is to be attached to the recovery of the metallic platinum contained in the unaltered salt, associated with the sensitive iron compound, which is applied to both the old commercial hot and modern cold-bath platinum printing surfaces. Indeed, it will be evident that spent oxalate developing solutions must carry down with them a considerable quantity of platinum, and hence its recovery should not by any means be neglected.

In our present number a correspondent from a distant part of the globe who, it appears, has been accustomed to work platinotype printing on rather a large scale, asks us to give a method for recovering the platinum from old developing solutions. The process is simple enough, and in describing it here we have little doubt that it will do a service to others.

The vessel containing the accumulations of the old developers is heated until the liquid reaches a temperature of about 180° Fahr., a saturated solution of ferrous sulphate in the proportion of one part to four of the oxalate solution being then added to it. Precipitation of a dark substance immediately takes place; this is finely divided metallic platinum. When the precipitate has settled, the supernatant liquid is drawn off, and the precipitate after being washed is ready, either for conversion into chloro-platinite or for transmission to the refiner. Probably the latter is the preferable plan.

Of the quantity of platinum salt with which platinotype paper is coated it has been estimated that far from all of it is taken to form the image, so that the wisdom of saving the developing solutions is manifest. The acid clearing solutions, however, only carry over but an infinitesimal proportion of the platinum salt, so that their preservation for the purposes of recovery would be futile.

Chlorophyll.—In view of the use of this substance in correct colour photography, it is interesting to note that the long-held idea that iron is a constant constituent is now stated to be incorrect, Dr. H. Molisch, who has recently been investigating the question, having found that iron was invariably absent in the ash of chlorophyll.

Photographic Patents.—A General Election is usually said to upset men and things. Has this been the case with photographic inventors, we wonder? In the list of over 350 applications for patents in the official journal last week there was not one that directly or indirectly related to photography. This is a most unusual circumstance, as of late years the applications for patents in connexion with the art have been very plentiful indeed, although a considerable proportion of them are not completed.

Photographs in Natural Colours.—In connexion with this subject, we have recently been visited by a gentleman who only the other day was in M. Lippmann's studio, and he informed us that that investigator is still pursuing his work in the same direction. Professor Lippmann some months since gave to him one of the spectrum photographs which created such excitement in the scientific world, but it is far exceeded in interest, he told us, by some of the later pictures, one taken of a combination of the French and the Russian national flags being strikingly real, and exhibiting the colours of the original in a very complete manner.

Cracked Negatives.—It is no unusual circumstance to find, after a negative is developed, that the glass is slightly cracked at the corner. If it be printed from in this condition, the chances are that the crack will extend, sometimes to the total destruction of the negative. If the attempt be made to cut off the damaged portion with a diamond, the pressure will often cause a split right across the picture. The best and safest way to deal with the fracture is to lead the crack out of the negative with a hot rod. If a piece of stout iron wire be heated and then the point placed on the glass a little in advance of the crack, the latter will follow the wire in any direction. By this means the fracture may be led to the edge of the plate, and thus further extension will be avoided.

International Copyright.—The recent law passed by the American Congress appears to be of very little protection to English publishers, as their works are still freely pirated in the States. A firm has, it appears, recently republished some of Messrs. Novello & Co.'s music. The latter have now commenced a test action against the pirates, and the whole of the home music publishing trade have combined together to bear the costs of the suit. This is as it should be. So far as pictures are concerned, the law is practically a dead letter, as we are told that directly European works are published in America they are systematically pirated. Notably is this the case with photographic reproductions of European works of art, particularly photogravures. In this direction the Continental publishers, we learn, suffer more than those in England.

The Next President of the Convention.—As will be seen from our report of the proceedings of the meeting of the Council of the Photographic Convention of the United Kingdom, which took place in Edinburgh on Saturday morning last, Mr. George Mason, of Glasgow, was unanimously selected to occupy the presidential chair at the meeting of the Convention which is to be held at Plymouth in 1893. We have little hesitation in prophesying that the conjunction of Mr. Mason as President with the same vigorous executive that has piloted the Edinburgh meeting through to such a remarkable success will result in an enhanced degree of prestige and good fortune for the Convention. The choice of the new President is a happy one, his extended knowledge of photography in all its phases, his high literary qualifications, and the universal esteem in which he is held by all sections of photographers admirably qualifying him for the honourable position he has been selected to occupy.

Holiday Work.—The holiday season is now on, and amateur photographers are rushing away with their cameras in search of the picturesque. It is a noteworthy fact that many amateurs will take a journey of perhaps hundreds of miles, and then expend the larger proportion of their plates on subjects such as could be obtained quite as well close at home, perhaps on a Saturday afternoon outing. This is rather surprising, as one would have surmised that the opportunity would be taken, in visiting a district, to take only such subjects as could not be obtained elsewhere. For example, in visiting, say Scotland or Wales, it would be well to secure, in all the pictures taken, something to identify them with those particular places. If this were done, most amateurs' collections would prove far more interesting from variety than they are. One country lane is pretty much like any other country lane, and pretty ones are to be seen everywhere. However, the amateur finds pleasure in whatever he does, and is not like the professional, who has the question of ways and means to consider.

Technical Schools.—A great deal has been, and is being said on the advantage of technical schools, such as those on the Continent. There can be no question as to the benefit to be derived from such institutions, but do they, in practice, prove of such value as some writers would have us believe? Let us take photography and its different branches as an illustration. From inquiries we have from time to time made amongst Continental workers, we have been given to understand that the knowledge gained at these schools, though thoroughly theoretical, is not of a really practical character. One gentleman, the head of a large photo-mechanical printing establishment, recently told us that pupils from these schools rarely knew anything practical of the different processes taught. Indeed, he said he would rather take those who were quite ignorant of the subject, and teach them himself, as they always made better workmen in the end than those trained in technical schools, as they had nothing to unlearn, which the others often had. We have heard similar opinions expressed by others on the Continent. However, one would think this should not be the case if the tuition were of the proper character, and this it is said to be in the Continental schools.

Coloured Pictures by Photographic Aid.—At a recent meeting of the Berlin Physical Society, Professor Vogel exhibited what is described as a remarkably fine series of coloured prints of oil paintings, &c., prepared in accordance with his method by Messrs. Vogel and Ulrich. His plan consists in first taking a red, a yellow, and a blue negative of the object, on plates specially sensitised for colours. The three negatives are then printed on one and the same piece of paper by means of complementarily coloured rollers or stones. In order to obtain the colours exactly complementary to those of the negatives, the colours used for printing were either the coloured sensitisers themselves, or some substance whose equivalence to these had been determined spectroscopically. The application of the physical principles involved in the above yielded an approximate reproduction of the natural colours, which is stated to be "surprisingly complete, and will become more so as more and more coloured substances are discovered suitable as sensitisers."

Lunar Photographs.—Dr. L. Weinek, of the Prague Observatory, has received several photographs of the moon from Professor Holden for the purpose of making enlargements from them, the negatives having been taken at the Mount Hamilton Observatory with their large equatorial. In *L'Astronomie* for June is an illustration of one of these enlargements. We have not in our possession a copy of that periodical, but *Nature* points out that it looks at first sight as if the amplification had been carried too far, though at arm's length the effect is very fine. "The most striking features are the narrow, river-like lines, which are numerous and very alike in appearance. Whether these are photographic or not of course we cannot say, as we have not seen the original negatives, but they seem to be rather too distinct and natural to be taken for any impression other than photographic." Thus the editor of *Nature*: to us the description reads exactly like that of the effect which would be produced from "crapey" collodion, an effect well known to all old workers in collodion. Whether our explanation be correct or not, it would appear to us that enlargements of this character would stand a far better chance of being well done if the work were put in the hands of a professional photographer accustomed to that class of work.

Copyright.—In the report of a recent meeting of one of the Metropolitan Societies things appear to have got a little mixed, and might convey to some the idea that there may be a copyright in a view—that is, if a particular view has been photographed by some one, and that person has made his picture copyright, that the same view cannot afterwards be taken by any one else. This, no doubt, was not really the idea of the speaker, though the report might give the opposite impression. We should not have referred to the subject, except for the fact that we frequently receive letters inquiring if, when a photograph of a landscape or of a building is marked copyright, any one is prohibited from taking the same subject from a somewhat similar standpoint. Evidently such an impression exists, at least in the minds of some people, or we should not have so many queries on the subject. There is no copyright in nature. If a person takes a photograph, or paints a picture of any particular view, he can make his photograph or painting, as the case may be, copyright, but that will not prevent any one else from producing another photograph or painting from exactly the same spot, and in every way the same both as regards size and style. It would, however, be legal piracy to

copy the picture that had been copyrighted. Nature cannot be copyrighted though a picture from it may be.

A Rapid Albumen Process.—In the article on the albumen process, a few weeks ago, reference was made to the fact that, by a modification of it, one of the most rapid pictures yet taken was produced, namely, when the late Mr. Fox Talbot, over forty years ago, photographed some printed matter fixed to a rapidly revolving wheel by the light from the discharge of a Leyden battery. Some correspondents have asked for a description of the modification that conferred such extreme sensitiveness. Here is a brief outline of the method as given by Talbot in 1851 :—A glass plate was first coated with a thin film of albumen, and dried. It was then treated with a very dilute solution of nitrate of silver containing a large proportion of alcohol, and again dried. Then it was washed, and once more coated with the albumen. After that was dry, the film was iodised by dipping the plate into a solution of proto-iodide of iron containing a considerable quantity of acetic acid and alcohol which had been made some time, so that acetic ether was developed. The sensitising was effected by immersing the plate in a strong solution of nitrate of silver strongly acidified with acetic acid. The plate was then exposed in the camera while wet. The image was developed with a strong solution of proto-sulphate of iron. It will be seen that this film contained nitrate of iron, and to this, no doubt, was due the extreme sensitiveness, nitrate of iron being a strong reducing agent.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

EDINBURGH MEETING.

At the Wednesday afternoon meeting, Mr. H. P. Robinson's paper was read by Mr. T. C. Hepworth—

INDIVIDUALITY IN PHOTOGRAPHY.

By H. P. Robinson.

In a recent number of *Blackwood's Magazine* an ingenious writer tries to show that the one thing more than another that now represents primitive man is the baby, and that the nineteenth century British baby differs very little from the savage child of, let us say, a couple of hundred thousand years ago, for the baby is nearly a quadruped, and is a reckless creature devoid of conscience. It is, perhaps, a knowledge of the fact that babies are all alike that enables photographers, as it is libellously said, to make the negative of one of the species satisfy the yearnings of many mothers. Now, photography is certainly somewhat like this view of the human race in the respect that its immature productions are all alike, and it is not until they grow up and acquire a conscience or soul that they differentiate and show individuality.

Of the immature there is no end, but a wise and invariable provision of nature checks over-production. Nature is always wise, but has no mercy :

> "So careful of the type she seems,
> So careless of the single life ;"

and, seeing that the world would be overwhelmed by immature photographs, she sent beneficent fading to destroy them (always, as in other departments of nature, "so careful of the type," sparing a few) until the art grew old enough to possess a soul or conscience, and then permanent methods were given to us; and even now we sometimes feel inclined to paraphrase the wisdom of Mr. Whistler, and say modern photographs do not fade, and therein lies their deep damnation. This wonderful preservation of a few in all their pristine freshness is suggestive of a special providence, for according to the scientists, who are, of course, always right, like methods should produce like results, and not one of the old prints should have escaped.

Now, evidence of soul or conscience in a picture is art. Yet there are those who will not recognise that we have a soul, but, like Mr. Gilbert's mechanical figures in the *Mountebanks*, are only stuffed full of badly made machinery that sometimes runs down, and always moves with a jerk; and I am not sure we are not suspected of trying to adapt the "put a penny in the slot" business to the fine arts.

It is a favourite reproach with the opponents of photography as a picture maker that its results are all alike; it is one of the triumphant proofs of those who will not admit that photography is an art that the unthinking machine makes all its products to the same pattern; that there is no intrinsic evidence in any photograph of its maker. They will no more believe the plainest evidence to the contrary than those of old would believe the angels. They say we are mechanical, and it is of no use pointing out that this wild assertion is obviously untrue, we hear it over and over again, sometimes from one who knows that it is not true, at others from those who are simply ignorant and cannot learn. These are to be pitied. Then, there are those whose purpose it serves to deny; and, worst of all, those who have tried, and altered their faith because they failed. those who, as the poet says, "fade away, and dying damn." To the credit of photographers there have been very few of these; however, we have lately had an exhibition of one of them. A most enthusiastic defender of photography as an art of a few years ago, but who, perhaps, failed to prove it in his works, was politely asked to contribute to a recent exhibition, and is reported to have replied as follows—it is a lesson on the mutability of things to compare this letter with his former opinions: "I am fully persuaded that photography is not art nor can be, and to encourage exhibitions is to lead a lot of vain people to waste their time in the practice of a useless and vain pursuit."

It has no effect with the prejudiced critic to point out, that if different minds using the same machines produced like results invariably, as machines are expected to do, any one of them who understood the machine ought to be able to turn out a series of masterpieces equal to the best that have ever been produced, always providing, of course, that one machine was as good, and as well brassbound and French-polished as the other. Yet they continue to say—and this is one of the latest utterances of science : "The picture painted by the artist is a transcript of his own emotions, but a photograph is not a reflex of human emotions at all—unless, indeed, accidentally so—but is a direct reproduction of nature, and only through science the offspring of man." We must be grateful to the writer for allowing us the accident.

I am quite ready to confess that up to a certain point, and in the hands of the ninety per cent. of the followers of the art who are not artists, the photograph is in the process; but with the others the picture is in the man (as in painting, only in a less degree, and as far as the materials will allow). The process takes a very subordinate place, and is dominated by the taste, thought, and feeling of the artist, when an artist uses it with what may be fairly called emotional results. Who has not laughed with many of Rejlander's characteristic heads, or wept—yes, I have seen even that emotional result produced by a photograph (which was not an accident), and it is an important part of my argument that all these emotions arose first in the mind of the photographer, and would never have been originated by the same models in the hands of another photographer.

Of all the attempts made to prove that photography was not an art, that which would have most force, if proved, would be that it showed no evidence of individuality; but, on the other hand, if the possession of that quality were proved, it would be one of the strongest arguments in favour of the admission of photography to the brotherhood of art, for individuality, in its products, necessarily implies the operation of a directing mind behind the "soulless camera."

The latest of the many attempts to define the meaning of the word "art" is a very remarkable one. It is said to be, "The apparent disproportion between the means employed and the end obtained." And, as an illustration, the following explanation is given, at which, I think, many a practical photographer will smile.

"Admit, for argument's sake, that a photograph reproduces with a fidelity far beyond anything that the hand of man can attain to, it must still be allowed that the means used to attain this end are infinitely more complicated than the few hairs tied to a stick which the artist uses. Indeed, it might be argued that, if *art* is the apparent disproportion between means and end, photography is not art at all, but science. There is no art on the part of the lens when it produces its images ; it does so strictly in accordance with natural laws. The developer acts as thoughtlessly as any other chemical experiment, and these are the chief factors in every photograph. It is true, you have one small part to play—you must have the *art* of exposing properly; but even here a few shillings will purchase for you a machine to do even this. I do not admit art in development. Art in development is only called in when the exposure has been made without art, and, as I have already allowed art in exposure, I cannot allow it here again. With such an infinitesimal part of the picture' the outcome of art, is it honest to call a photograph a work of art?' This curious example of scientific knowledge of art is by Dr. J. K. Tulloch, of Dundee, and was written in the present century. Are we to understand from this singular piece of reasoning that painting is an art because the painter uses "a few hairs tied to a stick?" and does the writer suppose that we claim photography as an art because of its fidelity—that heritage of the youngest amateur?

Some writers get confused between degree and kind. In an article in the *Magazine of Art*, a certain writer, who was once a photographer, endeavours to show that photography cannot become art, because its individuality is limited. That it is more limited than painting has always been admitted—we cannot get so far away from the truth as is the painter's privilege—but it is also admitted that all methods of art are more or less limited, and the amount of limitation is only a matter of degree, not of kind. The limitations add to the difficulty, but do not alter the status.

Let us run back a little and see if we can find a few workers whose results are totally different from those of their contemporaries, and this invariably. One of the earliest photographers to show genuine art feeling in his work was Rejlander. He died sixteen or seventeen years ago; yet, among many thousands of photographs, it does not require much experience to recognise a Rejlander. There was nothing in the manipulation to distinguish them, except, perhaps, carelessness. It was the mind of the man that was visible, you recognise the man beyond the process. There are still those living who can say, on looking at a collection of old photographs, This is a Francis Bedford, a Dr. Diamond, a Fenton, a Delamotte, a Le Gray or Silvy, a Wingfield or a Mrs. Cameron, certainly quite as accurately as an expert in painting would say this is a Raphael, or Titian, or a Correggio. Then, what becomes of the machine argument?

I will now endeavour to put it another way. Photographs, as I have endeavoured to prove, show the mind of the producer—when he has a mind to show—and given two equally gifted photographers, as far as equality can be measured, the one could not produce even a colourable imitation of the work of the other. Neither could dismiss his individuality let him try how he may. Take two representative men, Rejlander and F. Bedford, neither of these accomplished photographers could have imitated the other. They had both original minds, and followed the bent of their genius, and their hands, as well as brains, showed in every picture.

Among the workers of the present day, I could point to dozens of well-known instances, but one or two must suffice. No man's work has been more imitated than that of Mr. Gale. In every exhibition, he is imitated in size, style, framing, and signature, yet an expert can decisively say of two pictures, This is the Gale, and this the imitation; he can even distinguish between the imitators, and say, This is a ——, and this a ——.

Then, in a very different style, there are the works of our much-respected President, than whom there is no one I would prefer to see occupy the honourable position which defective health compelled me to decline. Perhaps I am not a fit and proper judge of his pictures, but, without altering my opinion of what a photograph should be, I must confess that some of them have captured my admiration for their beauty and respect for other ways than my own when in good hands. Now, some have endeavoured to imitate Mr. Davison, and some have renounced photography in despair, because they could only reach the eccentricity without touching the excellence. It is easy to put the image out of focus, but not so easy to make a picture by that means, and Mr. Davison makes pictures. It is easy to copy peculiarities, but not so easy to Imitate valuable essentials.

While on the subject of our President, may I be permitted to add—for he is now in a public position and open to our shots—that, however straitened his views of the practice of photography as an art may have been at one time, his opinions have constitutionally broadened down, until now the key-note of his teaching is liberty for all

We now come to another proof of individuality. It used to be the practice to insist on anonymity at exhibitions until after the judges had done their work: but this was given up when it became apparent that the judges usually recognised the work of the old hands, and the only nameless ones were new exhibitors. In America—at least, at the Convention Exhibition—the farce of the anonymous is still carried to such an extent that nobody seems to know, officially or otherwise, who the pictures are by until it is too late to be of any use to the exhibitors; and newspaper criticism has to be published without names. For, however the photographs may proclaim their authors, it seems to be etiquette to pretend not to know.

The difference between the works of some of our best photographers and those of the moderately successful can scarcely be due to a scientific cause, except, indeed, to a reversal of the generally received idea; for I think, if the truth were known, it would be found that the producers of the indifferent pictures had much more scientific knowledge than those who produce the most artistic pictures. I am acquainted with a great many of our photographers, but I do not know one of those to whom we are accustomed to look for the chief ornaments of our exhibitions who have any elaborate scientific knowledge. Indeed, their technical methods are so very simple as to seem quite elementary. They usually take a plate to the make of which they are accustomed, a simple pyro and ammonia developer, a handful of hypo, and a jug of water, and use them properly; and that is all. They do not bring science to bear even on the exposure, at the expense of "a few shillings." They get on without an actinometer. They feel from experience when their plate has had enough, and an actinometer, however perfect, would only confuse them. But, as they endeavour to put taste, thought, and feeling into their pictures, their works necessarily differ from those of the scientist, and the essence of their art is individuality.

My last word must be a word of caution. Be original, be unique if you can, but not out of harmony. Individuality goes wrong when it is out of harmony with its surroundings. Eccentricity is very easy, but it does not last. It is open to the meanest capacity, and is often assumed by it; but genius, to be useful, should consist of individuality, backed up by suitability to its environments.

Mr. Crooke said there was no doubt there was individuality in photography, and pointed to instances in which it was expressed. He thought that in many portraits of large size an advantage frequently arose from their not being in quite sharp focus. In small pictures sharpness was looked for as it was in a miniature. He was much pleased with Mr. Robinson's paper.

Miss Barnes had recently been out photographing with Mr. Robinson, and he said to her, "Now you have got some good exposures, see that you don't spoil them in developing."

Dr. Mitchell considered that no proper photographer could be an artist without possessing individuality.

Mr. Bothamley quite agreed with the paper. There were many photographs, as well as many paintings, in which there was no individuality; but they must judge photography by the work of the best men, for it was capable of producing artistic results.

The President said that it was not likely there would be much difference of opinion among photographers as to this, but many painters were greatly prejudiced. One of these had said in his hearing that, if six painters were given a definite subject to paint, the result would be six pictures each differing in character from the other; but set six photographers to work to reproduce it, and all six photographs would be alike. This he (the Chairman) denied. He advocated treatment of subjects broadly, which often did not harmonise with sharp focussing. He was much pleased with the paper, which bristled with good points.

The following paper was read by Mr. Bothamley in the absence of the author:—

PHOTOGRAPHY IN RELATION TO PAINTING.

By Arthur Burchett.

In commencing this paper on *Photography in Relation to Painting*, I feel that I cannot do better than give the definition of both painting and photography. Painting is a representation of objects on a flat surface, painted by the hand by means of brush, pencil, or other tool being under the will of the artist, unrestricted in fancy, subject, colour, form, place, or period. Photography is a representation of objects on a flat surface, restricted to the absolute reality of form present, as rendered by the lens on the sensitive plate in the camera, being only under the control of the photographer in development and in *choice* of subject, form, place, focus, and length of exposure, and in some few cases light and shade.

Such being the definitions of painting and photography, we can now see how very limited are our resources in photography, compared with painting, for producing a picture that shall have qualities that give it an art value, for it is not a mere transcript of nature that we require, but a picture containing some sentiment or idea that shall give pleasure to those who see it, and in nature there is in both figure and landscape an endless wealth of beauty that we can render, if we see nature with the knowledge of what the camera will do and what it will not do.

Photography being limited to reproducing the objects present without colour (which in painting is often its chief charm), we must therefore, find out how near photography approaches painting by comparing reproductions of paintings with the work of the lens. Unfortunately, photography is severely handicapped by the inability of the sensitive plate to render the true tone value of all colours, and this inability adds very much to the difficulty we have in judging Nature as she is represented in the photograph and in painting; but even with this defect the result in photography is very close to the true rendering of Nature, and will be even more so in time as photography advances. I need not point out the defects of photography with regard to

rendering colour into black and white, for we all know them. In painting, certain colours have a different tone value to some artists than to others, and, when their pictures are rendered into black and white, fail to recognise the likeness of effect to that of the painting.

Both in photography and painting we have to consider, in the construction of the picture, the possibilities of its being a success, its story, composition, light and shade, and all the various items that make its being. A painting or photograph must have some reason for existing, some object or story, and this must be the one thing that all else is to be subservient to. In a picture the artist tries all he can do to keep your attention fixed on his principal figure or object, and to do this keeps all his what we call "focus" on it, and all else is kept down both in tone and sharpness, so that the eye shall not wander away and become confused by the surroundings. Many pictures and photographs are spoilt by the want of concentration of interest, simply by forgetting this simple rule, in painting by over-elaboration of unimportant objects, brilliant colour or strength which kills the principal object in the picture; in photography, by microscopic focus, which puts everything on an equality with the principal object, accentuating things that are unseen by the eye, for the eye sees the thing that is, not what it is made of; a tree is made of many leaves, branches, &c., but the eye sees them as a mass of foliage, not as individual items.

Many pictures are spoilt by want of contrast of light and shade, for it is a well-known rule in art (and art applies to photography as much as painting) that, except in exceptional circumstances, there shall be no accessory object lighter than the principal object of the picture, or, if that is a dark, darker than this object. In this was the secret of the great success of the old Flemish artists, Rubens, Vandyke, Rembrandt, &c. Both photographers and artists cannot do better than carefully study the way in which these masters have managed the light and shade, both in portraiture, figure, and landscape.

The next thing to consider is the composition or arrangement of the figures or objects that constitute the picture or photograph. In painting, this is comparatively easy, as the artist can place his figures where he pleases, and use any kind of composition. But the photographer is entirely limited to a more or less equal plane of focus, owing to to the distortion the lens gives in figure subjects, for what is simple foreshortening in painting often becomes absolute distortion in photography.

Composition not only applies to the arrangement of the figures, but also to the light and shade, which must be so managed that it gives value to the lines of the figures, and in figure and landscape pictures so combine them that they become as a whole. With pure landscape photography, composition is impossible, as you cannot arrange your objects; you can only select a view, and can only use the knowledge of composition to help you to choose the best view. In landscape and figure pictures very much can be done in photography, but you are limited to simple arrangement in a selected landscape, which has to be taken just as it is, and which, in painting, would be so altered and arranged that it would carry the lines of the composition in harmony with the figures.

Light and shade in landscape, which are so important in painting, are quite as important in photography; but here, again, we cannot arrange like the artist, but are quite dependent upon the effect at the time of exposure, which can sometimes be chosen. It is a very great misfortune that photography will not render the true effect of cloud and sky, combined with landscape, for, until this is possible, we must depend upon the sky from another negative, which, more often than not, is entirely unsuited to the landscape, and also is, as a rule, printed far too heavy.

In painting, besides the great charm of colour, the artist has one which is, perhaps, greater, that is, "ideality," or the rendering of the image of the mind as opposed to the reality. Idealism in painting often merges into mannerism. There are many living instances of this, the weary repetitions of the same form and the same effect. In photography, the danger of mannerism is greater, as, if we use the same stop to the same lens, and the same printing method, our photographs must necessarily look more or less alike, only the difference of form. I suppose it will always be so, at least, with the majority of workers who only have one lens. Painting is very much like handwriting; one can recognise the author, but photography changes in character with every different kind of lens, so that it ought to be possible to escape from the more glaring faults of mannerism.

Impressionism must not be confounded with idealism, for impressionism is the rendering of the way the object or scene appeals to you —how you see it—whereas idealism is the correcting or altering nature to suit what you consider true beauty. Impressionism in photography is not only possible to a very large extent; but the results are very beautiful, and *do* depend in a very large measure on the artistic aptitude of the photographer, and the knowledge of his lens, and though, to those who are unable to see the beauties of nature (and they are legion), it may appear entirely chance work, yet those who use knowledge both of nature and photography, know that the results are precisely those that were aimed at.

And now we come to what is considered to be the great strength of photography, its imitation of form. In painting it is often colour that expresses form, such as grass, sand, and many other things. There the colour tells what it is, and the mind is satisfied; but in photography, unless there is a *sufficient* indication of form, the representation is vague, and leaves the mind wondering and unsatisfied; it is therefore necessary to the proper understanding of a scene or object that the definition of form shall be such that the objects are recognisable, but how far it should be carried is entirely a matter of individual feeling, for, as in the case of idealism, the perception of form is in the mind; to one person form is soft and without line, to another the feeling of form is so strong that he can only express himself by sharp outlines, it is only a matter of thought, for in nature there are no outlines. The impression of nature is to me a soft blending of colour and tones, quite unlike the rendering given by what is termed "a nice sharp photograph." One of the great difficulties both painters and photographers have is the introduction of figures into landscape so that they shall not intrude or attract the eye from the *motif* of the picture. As a rule, we find in the best landscape pictures that, if a figure is introduced, it is placed in the middle distance, and is used more to serve as a known size to give grandeur to the landscape. Turner was a master at this, and, though he defied this method in some of his pictures by placing the figures in the immediate foreground, yet he did it so well that they appear away from where the spectator stands, and therefore practically in what is the middle distance. Of late years it has become more the fashion to introduce figures in the foreground, so as to give a title to the picture, but it is very difficult to do so without sacrificing the landscape to the figures. Of course, these remarks do not apply in the case of what are called "*figure* and landscape subjects," for there the figure is the important object and the landscape only accessory.

I am afraid that my paper will not be considered complete unless I make a few remarks on motion as rendered by the camera and by the artist. I know that it is dangerous ground to tread upon, but I must needs venture. In the expression of movement in painting, the artist does not endeavour, like the photographer, to obtain a perfectly still look or an action that he cannot see, but such an action that shall express the characteristics of the movement he wishes to represent, whether it be running, leaping, falling, &c., and obtains that look of movement not only by the position of the figure, but also by means of flying drapery. Now, in pictures by many of the great masters, this drapery is painted in indistinct folds *purposely* to give the effect of movement. There is a very fine instance in the National Gallery, London, *St. George and the Dragon* (by Tintoretto), perhaps the finest example of movement ever painted. To say that movement must be expressed by movement expresses what I wish you to understand. In this picture not only do the figures seem to be moving, but the drapery vibrates; but still it has not the same kind of look that photography gives of the blurr of movement, but is of a character that I am afraid photography can never imitate. Another instance of the rendering of movement is Vandyke's drawings of the condemned being cast into hell. The mass of humanity seems to fall headlong. The effect of movement is indescribably true. When an artist looks at an instantaneous photograph of the movement of a figure, the chances are that he has never even dreamt of that representation being what it is intended to represent. The very fact of its being a *perfectly* arrested action takes away all sense of movement, and makes it only a pose. In landscape the expression of movement cannot be expressed by a perfectly sharp image. How often one hears the remark, 'This is not good, as the trees have moved.' Yet to an artist it is often the best quality that photograph possesses. Turner, the great master of movement, always got the effect of wind in his trees, waves, and sky by indistinctness of detail.

Sea and sky in photography are often perfectly representatives of movement. One need only see one of Dresser's seascapes to acknowledge this; but there are many other photographers who only give the arrested motion, the stillness of death, for it has the form but not the breath of life.

The imitation of nature should he in photography what artists have endeavoured in all ages to paint—that is, the life of nature not as a still, sharp microscopic image (for the time is past when we were content with seeing nature under this false light), but as a representation of life as seen by the eye, for what is false to the eye cannot

appeal to the mind. It may be a perfect photograph as far as exposure, development, and printing can make it, but, unless it has that something which truly represents the life of nature, it is worthless in an artistic sense.

Mr. Hepworth considered the most remarkable thing in this paper was an absence of the abuse which painters so lavishly hurled at photographers. It was doubtless accounted for by the fact of the author being a photographer as well as an artist.

Dr. Mitchell said the perception of movement was not satisfactorily effected by a too rapid exposure, which gave a crystallised expression that afforded no idea of motion; that was better conveyed by a longer exposure which gave a slightly blurred effect. He instanced Muybridge's running horses as examples of this. The eye saw only the combination of movements.

Mr. Sturmey reminded them that while the author belaboured painters, he also admitted that some of them made poses that were natural and artistic.

Mr. Cembrano, alluding to clouds in landscape, said many of those seen in nature were quite unsuitable from form and lighting to conduce to pictorial effect when photographing the landscape, and considered it much better to print in the sky from another and more appropriate negative.

Miss Barnes remarked that her teacher in painting, long before she took to photography, impressed upon her the necessity for noting the points of brightest light and deepest black in the subject, and avoiding allowing any other part of the picture to equal these.

Mr. John Fergus having made some observations,

The President explained that Mr. Burchett at one time lost his colour-sight, on which account he practised photography; but he was glad to say that his colour-sight had again returned to him.

AMATEUR PHOTOGRAPHY IN AMERICA.

By Catharine Weed Barnes.

It will be impossible to enter fully into the question of amateur photographic work in America, and I shall not attempt it, but, in considering a subject which necessarily involves comparisons between English and American work and workers, it is well, in all fairness, to have some clear idea, to start with, of how photography is pursued, and the opinion entertained of it in both countries. At present, and this is said advisedly, the English have the advantage at exhibitions of a higher general average of work, though I do not know if it is the case as with us, that many good pictures never reach the exhibition hall.

The amateurs in England, and in Europe generally, seem to believe in what they are doing, and consider it worth while to give the work proper time and care, working hard if need be to ensure good results; and this is half the battle. There are too many what might be called snap results with us, and the camera is still looked upon largely as a means to kill time, not worthy of respect for its own sake. We are too anxious to do things quickly, missing often thereby what only comes from patient, long-continued effort. There are instances among our workers of almost infinite patience and determination to show what photography can achieve in art, science, and general education, and such are filled with an enthusiasm which enables its possessor to think only of the end in view, and bend everything to accomplish it, regardless of mental or physical fatigue. The old painters were ignorant of many of our modern canons of art, but they had a worship for the thing itself, too often wanting in our utilitarian age, and the same may be said of photography. Altogether, too many workers begin and end with "detective" cameras. Why? Because there is a delusion abroad in the land that they are no trouble, require no brain exertion, are always available, and the user need not look upon his instrument as anything more than a toy. He generally expects, however, that same toy to possess all the photographic virtues of the widely differing branches of work. Beginning with clean, well-lighted portraiture, for instance, through the gradations of soft, atmospheric landscapes and marines, brilliant snap-shots and carefully managed interiors, it is expected all these may be made in the fraction of a second, and, of course, with a single view lens and cheap camera. I once received a letter, not at all an unusual one in my editorial correspondence, wherein the writer took several pages to explain what he wanted a lens to do, each requirement contradicting some other, and asked me to recommend a cheap one. My answer was that no such lens as he desired had yet been invented. The American worker, especially in small towns, is very often unable to purchase more than one lens, and yet is anxious to cover the whole photographic field. In such cases I always discourage hand cameras, as, under the best of circumstances, their results cannot fairly compete with tripod work, not merely because the latter is better in itself, but after taking the necessary trouble of setting up such a camera, one is apt to take more pains with the picture. Until one realises all the possibilities of time exposures, he does not begin to appreciate photography at its true value. A very encouraging sign of progress with us is the increasing number of organizations devoted to camera work. Hardly a week passes that a new one is not started; and their reports, as sent to our sanctum, show a constantly widening horizon of comprehension regarding the different fields of photographic usefulness being entered upon by workers in different professions. Physicians, painters, scientists of all kinds are utilising the vast help photography can give them, and are realising also, aside from that, the great and almost mysterious fascination it can exert, independently, on its own special account. A celebrated painter told me recently that he occasionally used an ordinary snap camera, not daring to attempt any of the actual work, or he should neglect his regular painting. I cannot but feel that to do camera work well, through all its countless ramifications—and what is worth doing at all is worth doing well—one must get rid of, and put behind him once for all, the idea that its limitations are as narrow as the illiberal prejudices of the past have settled upon. It is far harder to live down a prejudice than a principle, and that is just the task that lies before photography.

Experience, however limited, has taught me that, when a certain effect is gained in photographic work which at all departs from an ordinary photograph, if one attempts to help others by telling how it was done, his effort is looked upon as if he took his auditors behind the scenes at a theatre, and showed them how certain theatrical effects are produced. Probably the same thing is true this side of the Atlantic. A camerist should, above all things, never apologise for anything which will improve his results, because negative or print has been, as the unregenerate term it, "doctored." If a painter refuses to recognise the existence of an obnoxious element which would spoil his picture and simply leaves it out, why cannot the photographer use the only means at his command, and obliterate the object, whether on negative or print? Why should one be considered genius and the other a trick? The American public, as yet, has not been able to realise that photography has risen far beyond the high tide-mark of a generation ago, indeed that it is still rising. They are, as a rule, more anxious for something new than for steady progress in the work; but attendance at recent exhibitions has proved to me that photography is winning a high place for itself, if its followers will insist on not lowering its flag to the level of a trade, but keep it where it belongs, among the arts and sciences which are elevating the general education of the world.

One great cause for the success of European workers at our exhibitions is that we do not give enough consideration to the choice of a subject. We have not the wealth of historic scenes which the old world furnishes, and landscapes, *per se*, pall on one's attention in large numbers; but we are doing something, I am proud to say, to preserve a record of the historic landmarks we own, before the so-called march of improvement destroys them, to say nothing of also keeping a record of passing events, which afford an important field for camera workers. One of the societies with which I am connected has an historical section, whose members are detailed, when any specially important event occurs, to photograph it from different standpoints, thus obtaining a large and varied collection of prints in a comparatively brief time. About a thousand negatives were thus obtained at the centennial celebration of Washington's inauguration as President, which will eventually be of great value. This society's badge entitles the holder to entrance within the police lines at fires, parades, &c., and to work in the city parks. Both the large New York societies also give their members special privileges. This idea as to historical work is spreading among our societies with excellent results. The Chicago workers ought to take up seriously the matter of photographing at the Exposition, and a general protest is likely to be made against what appears to be the somewhat arbitrary ruling of the authorities. Permission should not be indiscriminately given, but under restrictions.

I have not been able to procure statistics as to the number of clubs in our country, but have visited many of the leading ones from New York to California, finding that, as in the case of the Boston Club, with its fine studio and meeting-room, each has some special advantage, but none offer better working facilities than the New York and Philadelphia Societies. The New York Camera Club talks of a special club-house, with separate studios, dark rooms, &c. A desire is spreading among the clubs for more practical instruction than is given in papers or discussions, and nowhere is this better shown than

in some of the smaller clubs. The idea, so general here, of camera trips during the summer is also gaining in favour with us. Women are admitted to membership in the greater number of our clubs, and in some of those who still hold out in the good old way their work is hung at exhibitions, their lantern slides shown on the screen, and I have spoken before several clubs which do not as yet admit women members, agreeing, perhaps, with a gentleman friend of mine in one such club, that a photographic society should be considered merely as a sort of masculine boudoir. Women workers are increasing rapidly among us, and it is only a question of time when they will be generally recognised as mentally fitted to improve the educational opportunities afforded by a club. Working by one's self encourages a narrow, prejudiced manner of judging one's methods and results, and women as well as men need to have their rough edges taken off by the sharp attrition of sharp criticism and discussion. We have in America what we call smoking concerts, which women, even if active members, do not attend, and it is only occasionally that a pipe or cigar is seen in the ordinary meetings, never at general entertainments. In the dark rooms the stall system is largely used as being more private, but the printing and slide work is done in a large room. Quite a number of our leading workers have their own developing rooms, and even portrait studios. In my own case, after making a portrait exposure and developing the negative, I take it to a professional friend of mine, who retouches when necessary, and then, unless in special instances, the sitter orders from and pays him for what prints are desired, the negative, of course, being held by me. I have not time to make so many prints, and sitters would not realise the extra labour involved, besides valuing the pictures more if obliged to pay something for them.

In landscape work the English have an advantage, rather than disadvantage, in their unduly blamed climate, far better atmospheric effects being gained in our clearer air; but they, as a rule, use heavier cameras than Americans. We rarely use an imported one a great while before beginning to make improvements in it, and, first of all, making it lighter, carrying the latter point even to excess. English cameras, unless of specially seasoned wood, are apt to warp in our drier climate, and I do not believe in, and certainly never saw, a single American worker using a wooden slide in his plate-holder.

Most of our finest cameras are made to have the ground-glass keep its position, even when the holder is slipped into place, and the tripod if made distinct from the camera, which latter I am not sure is an advantage.

Practical demonstrations and clear plain talks seem to be most enjoyed at our Society meetings, and when papers are read it is a rare case when the lecturer is not afterwards called upon by different hearers to explain various points still farther.

Dry plates are most generally used, though a few cling persistently to the wet process. One amateur I know of who coats all his lantern plates, and another, in preparing his, takes into careful consideration the special purpose for which they are to be used.

Only a few of our manufacturers make slide plates, and I consider it as somewhat unwise to make them more rapid than the English ones, which actual demonstration has proved to me is the case. It is claimed that slide-making is losing in interest, but such entertainments are always well attended, though the audiences seem to pay more attention to the subject of the slide than to its technical or artistic merit. We trust that European workers will in time see the advantages of our size negatives and slide plates, and that there is no actual need of using such very heavy cover glass. International exchange of slides is an idea worthy of cultivation, and is of value specially in encouraging all to do their best. Several of our amateurs have experimented in camera-making, and of shutter attachments there is no end. Our national fondness for haste has found a new vent in a kind of craze for instantaneous (I use the word under correction) pictures of racing, athletics, scientific experiments, &c.; but, on the other hand, that same tendency leads us to constantly invent practical, labour-saving appliances, wherein I claim we hold high rank, and many of our best workers have either personally made many such, or suggested them to some manufacturer, while one amateur has invented a shutter which allows several exposures per second. Orthochromatic work (or, I should rather say, colour-sensitive) is receiving more attention than formerly as the plates improve. They were supposed to be very difficult to develop, but at some of our recent exhibitions remarkable results from them have been shown, especially as regards flowers and delicately tinted drapery. As is well known, Mr. Ives is the only one among us who has succeeded in demonstrating what is hoped for from colour photography, but even yet he has a difficult task before him. Ordinarily, we depend for our finest lenses on foreign makers, but there has been a new one placed recently on our market by a New York amateur which, in the way of reducing harsh contrasts and allowing the shadows and half-tones to appear as in the gradations of nature, practically enters the field of orthochromatic work. It has a violet colour attachment, which can be screwed into the place of the rear combination of the maker's rapid rectilinear, wide-angle, or portrait lenses. It slightly increases the time of exposure, and the eye is at first disturbed by the use of the coloured instead of colourless lenses, but the results are remarkable, especially with portraits. The makers are also busy with a tele-photo lens, similar in some ways to Dallmeyer's and Miethe's.

There is a reluctance with us, in England, except among those amateurs who have been given over as incurable, to carry a size camera which will permit the picture to properly represent the view photographed. Even when intended for use in the lantern, the picture-takers too often prefer contact slides, simply, it would seem, because their physical strength is really or apparently inadequate to the carrying an 8×10 or 5×7 camera for the negatives, to say nothing of the extra exertion of reduction, but; as the French proverb says, "that which costs nothing is worth nothing." With regard to developers, many of us like hydroquinone, more still like it mixed with eikonogen, and others eikonogen alone, though I believe the majority, for regular work, prefer pyro and soda, as ammonia does not seem to agree with our plates. It would seem a good plan to test each new developer as it appears, for then, and only then, can the worker be really justified in making a choice. A number of our workers are expert chemists, and always prepare their own developers, not pinning their faith on ten per cent. or any other made solutions. As one of our writers has said, "A fool or a folly is no better for being an old fool or an old folly," and, if any method of work or modification of it suits our purpose, we do not wait until it is overgrown by the moss of tradition before recording our acceptance. Film rolls are much used in hand cameras, though magazines are preferred by those who keep to glass plates, and their number is increasing. Albumen and other glossy surface prints have been most generally used, though they are being superseded with our amateurs by the various matt-surface papers, especially bromide and platinum.

The question of exhibitions is not yet considered, as it should be, a valuable factor in photographic education, and we do not have enough of them. I cannot but wonder sometimes that judges are found willing to face the almost certain blame attaching to them, no matter how conscientious they may be. They are fallible—very much so—like most of us, and naturally praise what seems good to them, whether the general verdict agrees with theirs or not. The true benefit of an exhibition is gained when one ascertains not merely wherein his work excels, but wherein it is deficient. The general impression is growing that boards of judges should not be formed exclusively of either photographers or artists, as each is apt to be influenced by the prejudices of his own special education.

When will it be understood, both sides of the Atlantic, that photography in its dual nature of art and science is not necessarily a house divided against itself, and why is it not possible, as in the story of the gold and silver shield, to look at the question from both sides? Americans have not shown their full strength at European exhibitions, largely because notices of such rarely reach us in time for us to prepare and send any special work, and some international arrangement ought to be made, certainly on our side, to obviate the annoying delay in the Custom House. But I do not propose to discuss the tariff question.

Photographic literature should not be entirely passed over, and its importance is shown not alone in journals especially devoted to its interests, but by the way in which it is leavening our whole American literature. The daily press in many cases publish a photographic column, constant references are made to the subject, and many of our magazines give considerable space to articles on the work, or illustrate their pages from the results of the camera. Even the way in which the newspaper reporter attempts to be humorous on the subject shows a general interest in it. We have several magazines devoted to photography, professional and amateur, and they have a wide circulation. Our readers demand a great deal, being very particular also how it is presented, and those who undertake to furnish food for the average photographic brain have by no means an easy task.

It is often asked me if photography is not dying out, but I can most positively declare that with us it is most constantly growing. There are almost daily inquiries, of every one who is supposed to be an authority, as to instruments and methods of work, and it rests with our great army of amateurs to make their own place in the world.

Believe in what you are doing, and people will believe in you. The work should be followed not merely for personal credit, but for the work's sake and its value as a mental and moral education. I am glad that America has several representatives at this Convention, feeling it

will do much to strengthen the bond of comradeship between kindred bodies of workers. There should be only a sense of generous emulation on each side, and the tie of relationship not be weakened, though the ocean lie between us, for each can and should gain by mutual help.

As our great poet Lowell says,—

"For mankind are one in spirit, and an Impulse bears along,
Round the earth's electric circle, the swift flash of right or wrong.
Whether conscious or unconscious, yet Humanity's vast frame,
Through its ocean-sundered fibres, feels the gush of joy or shame;
In the gain or loss of one race all the rest have equal claim."

Remarks of a complimentary nature to Miss Barnes, and on the Chicago Exhibition, were made by Messrs. Taylor, Ward, Bothamley, Sturmey, Hepworth, and Dr. Mitchell.

On Wednesday evening the following paper, in the author's absence, was read by Mr. Cembrano:—

DEFICIENCIES IN THE TRAINING OF PHOTOGRAPHERS.

By E. Howard Farmer.

Early Guidance.

When it is known in the early life of a lad that he will probably become a photographer, his training should commence during the latter years of his school life. His studies can then be guided in directions which in after-years will be directly useful to him in his professional capacity, and he will acquire knowledge readily that may later save him much labour and effort.

Where this has been done it will be generally found that the directing parent is a photographer or connected with photography, and in such cases the same forethought which has guided these early studies into useful channels has probably continued their direction to a successful *dénouement*.

Importance of Continuity.

But the majority of those who become photographers have their career decided after leaving school—sometimes a good many years afterwards, and it is to these my remarks more especially apply.

We may suppose a lad has left school, and not until he has subsequently spent a year or more in holiday-making is the important decision made as to what his life's work shall be, and steps are taken to start him on his career.

Now, while the whole of our sympathies may go to aid the lad's pleasures in the heyday of his youth, the stern competition of life enforces the doctrine that this, the most valuable portion of his life from an educational standpoint, must be utilised to the utmost, and in doing this there is no need to deprive him of his pleasures, but they must come in as a complement, forming natural divisions to his work.

It is well known among teachers that the assimilative power for new knowledge usually falls off very much after the age of twenty or so is reached. This is especially the case when a lengthy gap or interval has been allowed to occur in the training, and a mass of evidence to support this occurs with photographers in the very small proportion who, however hardly they may be pressed, attempt even to increase their knowledge; and the steadfast application required from those who do, it is not too much to say, that independent of the inferior value which knowledge acquired at the age of twenty-five to thirty possesses, as compared with the same knowledge acquired at from fifteen to twenty, the labour and application necessary in its acquirement is three or four times as great at the more advanced age.

It is from considerations such as these we are forced to conclude that in allowing a lad's training to stop suddenly when he leaves school, even if only temporarily, not only are the best fruits, which might readily follow from the cumulative effect of his previous training left ungathered; but, before he has arrived at an age when he himself may fairly be held in some measure responsible, his future status is placed in jeopardy.

Deficiencies of the Apprenticeship System.

We may next suppose that the lad forming our example is apprenticed or placed to learn his trade with some firm of photographers. In accomplishing this, the parent very frequently considers that he has now fairly started the lad on his career, and, so far as any further training is concerned, leaves it to the care of his employers and the lad's own devices.

Almost universal as such a method of starting a photographic career is, the demonstrable insufficiency of such a procedure is only too complete. In the first place, the professional education, excepting so far as acquiring manipulative skill and a knowledge of some aspects of the commercial economy of the business is concerned, leaves off where it ought to begin, and, although no one will hesitate to admit the prime importance of manipulative skill and of business methods, the trained photographer nowadays requires a great deal more in order that he may attain any *status*. In the second place, even the manipulative work is confined to one or two specialities, whereas the student wants at this, the very early stages of his career, and before specialising, trial practice in all branches. Thirdly, the skill acquired will depend largely upon the attention devoted to the student by the employer and fellow *employés*, which introduces an element of uncertainty into the training, and to which may be added the inevitable proportion of time which is wasted or during which no progress is made. There are also other reasons which at first sight are not so obvious; why the old system of apprenticeship, which is fast disappearing in other trades, must also in photography disappear, or be largely modified and supplemented, in order that the photographer may not only acquire an honourable *status* in his profession, but also keep on a distinct level above his neighbour the amateur.

Technical and Art Training—the Necessity for.

After his training has commenced, our supposed young apprentice finds there are at least five distinct sides to his subject, as follows:—

1. The Practical or Manipulative.
2. The Technical.
3. The Commercial.
4. The Artistic.
5. The Scientific.

Each of which requires his attention in a greater or less degree according to the character of the work to which he intends devoting his abilities. To convey some definite idea of the average relative importance of each of these divisions, it will be necessary to consider them individually.

1. *Practical.*—The manipulative skill required for most branches of photographic work is not of a high order; for example, the actual operations involved in the taking of a portrait negative are all of a fairly easy character, and require but little experience and practice on the part of a student to perform them with regularity and success. Notwithstanding this, the chief help which the student usually derives from his work in the studio is confined to a sufficiency of experience in these easily acquired manipulations.

There is, however, one special branch of studio practice which requires a very high degree of skill, and that is retouching. In other departments of photography also, such as working large wet plates successfully; some portions of process work; and others, considerable manipulative skill is essential.

2. *Technique.*—It is not difficult to show that the main foundation of photography, as a profession, lies in its *technique*.

Whether in the artistic or scientific departments; in landscape; seascape; motion; architecture; reproductions; or printing processes; the worker who is trained in either of them is the one who excels; and on examination, it is found that the success depends not so much upon any particular difficulty in performing the necessary operations as upon *a complete familiarity with the minutiæ and details of procedure*, which give the best result under particular conditions. The reason that several years' training is commonly necessary to get a fair percentage of successful results in any one of them is due to the fact that the worker has not had the opportunity of learning, in a systematic form, the *minutiæ* and special factors which govern different classes of work, but is left like a man groping in the dark to find his way slowly and laboriously by the method of trial; and, even if he has the guidance of a fellow-worker, it is one who has found it himself by trial and experience, and can only impart it in the same manner.

Take two beginners of identical abilities, perseverance, and general education; give both the average training obtained as apprentices to a photographer, and give one of them, in addition, systematic instruction in *technique*. The latter will become as good a photograph in one year as the former will in four years, and will ultimately become a much more competent and independent worker.

3. *Commercial.*—Important as a training in commercial economy undoubtedly is, which includes such subjects as economy of time, material and wages; value of specialism and enterprise; punctuality, tact, and politeness; treatment of employer and *employés*; accommodation to circumstances; and, in fact, all the *minutiæ* which together form the system of a successful business man; this side of his training is one which, in great measure, would be the same in all trades, and which therefore is rather included in his general education than in his specially photographic one. That photographers as a body are behindhand in this department of their training is, however, a fact very widely conceded.

4. *Artistic.*—The value of an art training is second to none in the whole range of a photographer's studies, as it invariably gives the stamp of refinement and superiority to his work. This is abundantly

testified in public displays of photographs, where the pleasing effects produced by artistic feeling or culture deservedly take the first rank.

5. *Scientific.*—The value of a purely scientific training to the *working* photographer has, in my opinion, been a great deal over-estimated. In the early days of the art, when the worker had to go through a series of delicate chemical processes for each photograph taken, and when the successful performance of these processes was alone sufficient to tax the knowledge and skill of one individual, it may have been true that a trained scientist was the best man. But, in these days of dry plates and ultra-simplified printing processes, photography, except in its purely scientific divisions, is being lifted above a test of chemical knowledge or optical expertness, and, in taking its place as one of the most valuable handmaidens the fine arts possess, must sooner or later be admitted into partnership with them.

The chief use of a knowledge of chemistry, molecular physics and optics to the photographer, independent of the general educational value; lies in their giving him a clearer insight into the sciences utilised in his work, and thereby inducing an interest which acts as a powerful antidote to the apathy which is so fatal an enemy to progress.

More Care Required in Specialising.

Another division of his subject is recognised by the photographer more and more clearly as his work proceeds. Having probably started by associating photography with taking portraits only, he becomes conscious of fields and scope for work in which portraiture plays no part; he finds workers devoting the whole of their time and energies to landscapes, to copying, to architecture, to printing, or to process work; and even in portraiture alone he finds one worker devoting himself to operating, another to retouching, and a third to printing. He begins to realise that it is impossible for an average individual to master every branch of photography, and so it comes about that he, like the others, has to select some departments and reject others—in fact, specialise.

In doing this, he is usually guided by what he considers the most lucrative portion of the art, and in most cases portraiture seems to be chosen. It is, of course, a matter of opinion as to which branch of photography offers the most lucrative openings; but in my opinion the prospects of a landscape or general worker, or a reproductionist, at the present time, are better than those of a portrait photographer, these prospects being not so much in the silver print as in the collotype film, the copperplate, or the type block.

There are other factors also which should be considered in deciding upon the direction in which to specialise. The probationist, while it is still in his power, should be guided more by his own capacities and temperament than he is at present. If he likes indoor life and delights in the human figure, he would be unwise if he did not take up portraiture; but, if an outdoor life suits his constitution and tastes, he would be equally unwise if he did not specialise in landscape or other outdoor work. For town life he must be more expert and specialistic than for country life, for which a good general excellence is better suited. And, again, according to his proclivities, he should choose the artistic or manipulative sides of his subject.

Whatever special branches he ultimately adopts, a good general commercial and art education, and a good technical and trial knowledge of all the principal photographic processes, with their individual applications and possibilities, should form the basis of his work.

Evidence of the Present Insufficiency of Training.

Evidence of the insufficiency of the present system of photographic training is everywhere present.

In the extremely limited range of most workers' skill, which, while good in itself when carried to sufficient perfection, and supported upon a general foundation, is frequently mere rule of thumb, so that the results are capricious, and, in taking up new processes or methods which the progress of technology or discovery may render advantageous, the worker finds himself but little better than a novice.

In the deficiency of technical, artistic, and general knowledge so commonly met with, which, while it is excusable among those who, interested in photography, are not expected to know its minutiæ; it is inexcusable among those who, by their calling, are expected by a public—quick to criticise harshly—to have been properly educated in the art they profess.

And, last but not least, in the surprising facility with which a determined outsider will place himself on a level with workers of a lifetime.

The Probable Remedy.

It is, I believe, in the spread of a sound and largely extended intermediate and supplementary training to that of the school and the studio that the photographer will not only occupy an impregnable position as a specialist, but will also learn how to utilise to the *uttermost advantage* the factors and processes at his disposal, and in so doing will both kill the untrained competition from which he in so many cases at present suffers, and will place his business on the soundest of all foundations.

Mr. Wollaston said that Mr. Farmer had omitted mention of a particular training which was of great importance to a photographer; he referred to *business* training. Ordinary assistants and apprentices seemed to be lacking in that essential.

Mr. Ward observed that there was an almost unlimited demand for good assistants, and if quite a large number were properly educated, they would find good and permanent situations.

Mr. Welford said that while all-round men were generally desired, such men, when employed, were usually given one special thing alone to do.

Mr. Anckhorn considered that if an assistant pushed his way he would get on. Young men should have proper training, and be indentured for a term of years. If a clerk or business man was wanted, they could get one at a pound a week.

Mr. H. M. Smith said that Mr. Farmer seemed to want a gentleman who was a paragon of all the virtues—one who was a good scientific man, a good business man, and a good photographer. But a scientific man was not usually a good business man, and, contrary to Mr. Anckhorn's statement, you cannot get a good clerk at a pound a week.

Mr. George Mason stated that the position of operators depended upon themselves. They ought to be able to retouch, so that when any department is vacant they could step in and fill it. The man who taught himself would by-and-by be able to teach his employers. Many operators held ridiculous opinions regarding lighting and apparatus: some, upon entering a situation, could not work because the lighting differed somewhat from that in their previous place; others who had been using a lens or a camera by one maker could not take a picture with that of another maker, and so forth.

Mr. Kidd's experience was that a man did not desire to do more than one particular kind of work. The want of knowledge among assistants was entirely due to themselves. This was also the case in other professions and businesses.

Mr. Deed advocated the establishment of a training institution to enable photographers to rise and become higher men.

The President said that Mr. Farmer's paper pointed in the direction of which Mr. Deed spoke—the establishment of an institution where all kinds of scientific and technical knowledge could be obtained. There were certainly openings in portraiture for operators possessing highly artistic skill.

After some observations by Mr. Warnerke on Continental establishments of the nature indicated,

Mr. Bothamley occupied the remainder of the evening by giving an address on Development.

On Thursday evening the following paper was read by the author:—

THE COLOUR SCREEN IN LANDSCAPE PHOTOGRAPHY.

By Charles L. Mitchell, M.D.

The value and use of orthochromatised emulsions in landscape photography is now fully recognised; but, as yet, there still appears to be considerable difference of opinion in regard to the necessity of the coincident employment of the colour screen. It is stated by many of the manufacturers, who at present supply the market with iso or orthochromatic plates, that the use of this valuable adjunct is by no means necessary, and that equally good results can be obtained without it. Having, during the past two years, made extended trials for landscape purposes of orthochromatised emulsions, coated on both glass and celluloid films, and during these experiments made frequent use of the colour screen, a few notes on the principles and methods of its employment may perhaps be of interest. The class of subjects selected was almost exclusively landscapes, and the large majority extended landscapes in the mountainous regions of Switzerland, Norway, and Northern Italy, involving distances ranging from ten to one hundred miles. The first year the colour screen was used sparingly, but the results obtained with it were so satisfactory that in the following year it was used whenever possible, and the success attending its use was so marked, and the quality of the work so far

superior to the portion in which the screen was omitted, that I now am fully convinced that the colour screen is an indispensable adjunct for any extended or comprehensive landscape work. The reasons for this opinion are not hard to find. It is a well-known fact that, when an open landscape is photographed on an ordinary gelatine emulsion, two serious difficulties are always encountered. These difficulties bear such a relation to each other that the means employed to prevent the one always increase the evil effects of the other. I allude to the difficulty of obtaining even and harmonious exposures for both near foreground and extreme distance. The rapidly vibrating blue rays coming from the more distant portions of the landscape produce, in an extremely short time, a very powerful reducing effect upon the emulsionised silver salts, and that long before the more slowly vibrating rays coming from the nearer and generally darker foreground have had time to properly act on the plate. The consequence is that, when proper definition, detail, and colour value have been obtained in the foreground, the distance has been so over-exposed as to solarise to a greater or less degree that portion of the image. On the other hand, should the exposure be so shortened in time as to obtain proper values for the distance, the foreground is so hopelessly under-exposed as to be but an unmeaning smear of black, devoid of all detail.

All kinds of devices have been suggested for remedying these difficulties. Sky shades, shutters having apertures of different shapes fancied to diminish to a certain degree the exposure of the sky and distance, &c., have at different times been suggested, but none of these have proved of sufficient value to become popular.

The difficulties, as above noted, are particularly noticeable in the case of Alpine landscapes. Here, then, is often a foregrounnd of rocks and dark pines, abounding in dark greens and browns, and opposed to it a distance composed of brilliant snow-white peaks and glaciers, standing out against a deep blue sky, varied, perhaps, with floating clouds. With an ordinary emulsion it is almost impossible to render properly such a landscape, as the foreground will be under-timed and lacking in detail, or else the peaks and sky will be so over-exposed or "burnt out" on the negative as to render the demarcation line between snow and sky almost indistinguishable. When, however, certain colouring agents are added to the ordinary emulsion, as is done in the process of orthochromatising, an entirely new condition of affairs is brought about. I will not attempt to explain this in detail, for it has and will be done by much more able and qualified hands than mine. Suffice it to say, briefly, that while the emulsion is now, in its altered character, a little less sensitive to the action of the blue rays of the spectrum, it is more sensitive to the yellow, green, and red rays coming from the opposite end of the spectrum. A plate of this character, when exposed to the same Alpine landscape as previously tried, would exhibit much more detail in the foreground, and the distance would be in much better tone. But, although the sensitiveness of the plate, as orthochromatised, is of a much less degree as far as the blue rays are concerned, they are so powerful that they still act too rapidly on the emulsion, and it is desirable to limit still more their effect. This is accomplished by the colour screen. A suitable coloured medium, in this case yellow, is interposed between the object and the sensitised plate. This medium intercepts the passage of the blue rays to a certain extent, or diminishes the rapidity of their vibrations, and, while prolonging thus the exposure, allows the reds, greens, yellows, &c., to pass through without hindrance and impress themselves fully upon the plate. The resulting image will now represent in much more accurate colour tone, as expressed in black and white, the different values of the landscape, giving full detail and softness to the foreground, and showing in the distance white peaks against a darker sky.

For purposes of landscape photography the colour screen employed should generally be of a light yellow shade, except in some special few instances, when, to obtain particular effects in a landscape, coloured screens of more or less of a red or reddish orange may be found to be desirable.

From this brief explanation the principles which govern the employment of the colour screen may be made apparent, and on its very face the theory of its action would seem to be correct and of sound value. And I unhesitatingly assert that, when the colour screen is *properly* used, the results will, in every instance, bear out the sound principles of the theory. Landscapes when, while full justice is given to atmosphere, the distant ranges of hills are as clearly defined as they would be to the eye; water which looks like water and not an expanse of snow; foliage and verdure which show the varied shades of greens with which nature bedecks herself; or the varied tints in an autumn landscape, and clouds of white or pale grey floating on a darker sky, as we see them daily in the heavens. But a colour screen should be used with judgment, as should every other photographic adjunct, if good results are to be secured; not for every subject, or for instantaneous work, or generally for objects close at hand, but for the special work for which its usefulness has been explained. Let us for a moment consider this and its practical features a little more in detail.

The first point to be considered is the colour screen itself. This should be of glass, perfectly flatted and ground to a true surface, or else it will produce such an amount of distortion as to render it totally unfit for use. In England, I have been informed, one or two firms offer for sale colour screens made of yellow pot glass, ground and polished to a true surface. The only one of these I have been able to see was of so light a colour, and that more of a brown than a yellow, that I should feel afraid to use it. The quality of others may be better. It is very easy, however, for any photographer to prepare his own screens, and of whatever colour he may desire, by a process which I shall now describe.

Procure plate glass, thin, perfectly flat, ground, and free from all striæ or bubbles. The thin plate glass that is frequently used for making colour cells and animalcule tanks for the gas microscope will be found to be excellent for this purpose. After being cut in small squares of the size desired ($2\frac{1}{2} \times 2\frac{1}{2}$, and $3\frac{1}{4} \times 3\frac{1}{4}$, I have found answer nearly every purpose), a square should be flowed on one side in the same manner as when coating a plate with collodion, with a solution of the colouring agent in amyl-acetate collodion. The colouring agent may be either "aurine" for orange red, or any other colouring matter desired, provided it is soluble in the varnish. For the yellow screen I am in the habit of using an aniline dye, called "golden yellow," in the proportion of from five to eight grains of the dye to the fluid ounce of varnish, according to the depth of tint desired. It is permanent, does not fade to any extent, and gives a rich lemon-yellow screen. The amyl-acetate collodion, now extensively used in the United States for the purpose of lacquering gas fixtures and brass work of all kinds, is known in trade by a number of different fictitious names, such as "enameline," &c. It is simply a solution of soluble nitro-cellulose in mixtures of amyl-acetate, ether, petroleum, benzine, and alcohol, mixed in varying proportions. It can be easily prepared on a small scale by cleaning off the emulsion from a spoiled celluloid film, cutting the film up in small strips (soaking them well in strong alcohol to remove the camphor), and placing these in a bottle with a mixture of one part amyl-acetate, one part petroleum benzine, three parts alcohol, and three parts ether, all by measure. The celluloid swells up and dissolves rather slowly, hence the bottle containing the mixture should be well shaken at intervals for several days. A better collodion is made, however, by dissolving good nitro-cellulose in the above mixture. When the celluloid is all dissolved, the liquid should be filtered through a little absorbent cotton to remove any loose flecks of dirt. This varnish gives a tough film, clear and free from transversed striæ, and is also an excellent material for varnishing glass negatives or positives, being perfectly waterproof. To resume, the glass square, after having been coated with the coloured varnish, is allowed to "set" for a few moments, and then placed aside on a flat surface until the varnish is perfectly hard and dry. Care must be taken to keep it covered while drying, so as to avoid dust and dirt settling on it. The coated plate is now placed on a level surface, film upwards, and sufficient pure Canada balsam (white and free from dirt) poured on the plate to make a pool in the middle of the plate of about one-fourth of its area. A fresh, clean glass square of the same size is next taken, and gently lowered on the balsam and plate in the same manner that a cover glass is placed on a microscopic object, and then a gentle and even pressure applied until all air is forced out, and the two glass surfaces are cemented together with the balsam and are in uniform contact. The cemented plates are now laid aside on a flat surface, and allowed to remain several weeks undisturbed, until the balsam has thoroughly hardened. Then the edges are cleaned off, the exuded balsam being removed with a little benzine or benzolo, and the edges bound with some strips of lantern-slide paper. This colour screen can be placed either before or behind the lens. If before, a special hood for each lens must be made to hold it. I therefore prefer to use it *behind* the lens, on the inside of the lens board, when it can be placed or removed in a few seconds. This can easily be arranged with two small brass or wooden cleats, secured down on the inside face of the lens board, and adjusted so that the colour screen can slide between them.

The next item is the subject. It is hardly necessary to say that moving objects and all instantaneous work are entirely beyond the scope of the colour screen owing to the length of exposure required. Moving clouds can often be satisfactorily photographed when the motion is slow, and the exposure made with the full aperture of the lens from half to two seconds being generally sufficient. Large masses annulus clouds, and also the lighter and more graceful forms of

cirrus, can be made, when at rest, to repeat themselves on the photographic plate with rare fidelity by the aid of the colour screen. There are many days of the year when these remain almost quiescent in the sky, and, as no great stopping down of the lens is needed, a large aperture and short exposure will yield excellent results.

For ordinary landscape work in close proximity to the subject the use of the colour screen is unnecessary, unless some special conditions of colour exist. Still life, fruit and flower subjects, however, are especially fruitful fields for the colour screen in conjunction with the orthochromatic plate. Here time is of no importance, absolute sharpness and fidelity of detail can be secured by stopping down the lens, and, with a full exposure, every feature of the object will be reproduced. The principal use of the colour screen in landscape photography, however, is in field work, especially where extended country, and often extreme, distance, are concerned. Here the colour screen is an *absolute necessity* in order to secure uniform and satisfactory results. I have photographs in my collection taken from the summit of the Furca Pass in Switzerland, where, while the foreground is harmonious and full of detail, the Alps of the Mounts Blanc and Rosa group are distinctly visible, although at least sixty miles distant. I have also noticed in the use of the colour screen, when photographing in both Switzerland and Norway, has given much more brilliancy to the dull monotone so often noticed in the photographic rendition of long stretches of bare mountain side, it seeming to differentiate and accentuate the different tones of browns, dark greys, and greens so prominent in such landscapes. In fact, I have grown to rely so much upon the colour screen in photographing these extended views that I fear no landscape, no matter how extended, provided it is properly lighted, and I think I can show as satisfactory results for such subjects as it is possible to compress into the limits of a small photographic plate.

A word may also be said just here in favour of the use of celluloid films. Glass is as yet undoubtedly the most perfect medium of support for the photographic emulsion. But it is heavy, liable to break, and for distant landscape work apt to show halation. This latter, it is true, can greatly be prevented by backing the plate, but it is a tedious, dirty process, and involves infinite trouble. Celluloid, as now prepared in the United States, is rapidly taking the place of glass for tourists' work. It is now manufactured almost free from defects, and is so light and portable that a gross of 8 × 10 size will take up no more room, and weigh no more, than one dozen of the same size of glass plates. It cannot be broken, and, moreover, is almost entirely free from halation, owing to the thinness of the film and the consequent absence of reflecting surfaces. To illustrate its advantages, I may say that last summer I took a three months' trip through Norway, carrying with me, in a small Norwegian trunk, together with my clothing, sufficient material for six hundred 8 × 10 exposures. The weight of these films was about thirty pounds; the same amount of glass plates would have weighed over four hundred pounds—an almost insurmountable burden, unless one travelled with a baggage train.

It remains to say a few words concerning exposure and development. Exposures for orthochromatic plates should *always* be fully timed to secure soft and harmonious negatives. An under-exposed orthochromatic plate or film is much more inclined to fog on development, and is much more harsh and lacking in detail than an ordinary plate of the same speed would be if subject to the same conditions. On the other hand, the orthochromatic plate, and even more so the film, will bear an amount of over-timing which would simply be ruinous to an ordinary plate. When a colour screen is used the exposure should be prolonged eight or ten times, and my friend Mr. F. E. Ives, who is world-celebrated for his researches in colour photography, has assured me that twenty times is none too much. I have no doubt some advocates of rapid exposures will be shocked by this statement, but, when we consider the retarding effect of the colour screen, the amount of "leeway" in exposure is in consequence immensely extended. In all such work plenty of time in exposure is necessary to obtain full detail. The distance will take care of itself, so will the clouds, and unless there is a brisk wind blowing they will show up all right in the negative. Furthermore, in overcast and cloudy weather, exposures on orthochromatic emulsions, either with or without a colour screen, must be greatly lengthened, much more so than for ordinary emulsions under the same circumstances. For instance, if I gave two or three times the exposure (using an ordinary plate) on an overcast day that I would on a bright, clear day for an orthochromatic plate (using no colour screen), I should give from *four* to *eight* times the exposure, and, if I did not do so, I should get an under-timed plate. If a colour screen is used in addition, the exposure should be increased proportionately as previously mentioned. Most of my failures with the colour screen and orthochromatic film have been from this cause—under-timing on cloudy days. There seems to be, under these circumstances, an absence of certain light rays in the atmosphere (yellow perhaps) which ordinarily affect more quickly the orthochromatic emulsion. After I discovered this I have frequently, after making an exposure, the time of which I had judged should be ample, made a duplicate exposure, in which for purposes of experiment I doubled the exposure, and almost invariably the longer-timed negative came out the best.

Finally, a word or two may be said regarding the development of the exposed plate or film. The developer used must depend largely upon the purposes for which the negative is to be used. If for bromides, lantern slides, or transparencies, my preference is for the mixed developer of eikonogen and hydroquinone, it giving negatives possessing the full detail and quick-printing qualities especially requisite. For platinotype, plain silver, and kallitype, I am growing to believe that pyro gives perhaps better results. The steel or blue-grey image produced by the mixed developer gives a density which seems greater than in fact it really is, and in printing processes which tend to diminish contrast it will not give as brilliant and "plucky" a print as will the slightly yellowed pyro-developed negative.

During the reading of the foregoing paper, Dr. Mitchell exhibited several specimens.

Mr. Bothamley said, that in the absence of the colour screen, frequently no advantage was gained by ortho-chromatic plates. This he had ascertained by experience when photographing on the Wye with Mr. Pringle in 1889. In summer, and with foliage, there was less advantage than in spring and autumn. He used plates colour-sensitised, by dipping in a bath of erythrosine and ammonia, and this, with a lemon-coloured screen, was very sensitive.

Mr. Warnerke asked whether a matt, or a polished surface of celluloid, was best to be coated with emulsion.

Dr. Mitchell was not yet prepared to say. Opinions differed.

Mr. Wollaston endorsed what Dr. Mitchell had said regarding photographing on a cloudy day.

Mr. J. Traill Taylor said, that when making a colour screen, instead of having to wait several weeks before it was ready for use, as mentioned by Dr. Mitchell, the operation could be completed in one or two hours by applying heat to the balsamed plates, as done in cementing lenses.

Several speakers, including Messrs. Tate, Weir-Brown, Keene, and Miss Barnes, then made remarks on the subject of orthochromatic photography, but the chairman pointed out that the subject was the colour-screen, although he would express his opinion that the photographer who once got at home in working orthochromatic plates with the screen, would not readily give them up for ordinary plates.

Mr. Ward then brought forward a motion that a request from this Convention be forwarded to Chicago to request that facilities be afforded all photographers to take pictures during the Exhibition there next year. This was unanimously agreed to.

The following paper was agreed to be taken as read:—

HOW TO LOOK AT PHOTOGRAPHS.

By F. M. Sutcliffe.

Photographs are generally said to show either technical or artistic excellence. Sometimes both qualities are visible in the same piece of work, sometimes they are not. There is another quality which ought to be present in all photographs, without which no photograph can be considered perfect; and, until this quality has been recognised, the photographer should stop before he pats himself on the back and says, "What a good boy am I," after he has taken what he may look upon as a perfect piece of work, as an example of technical skill, or as an attempt at picture-making; it may be clever, yet for all that it is a failure if it cannot *speak* to those who look at it.

There has been, as you all know, a lot of strife between what has been called the old school and the new, or the sharp and the unsharpened; it seems to me that, if both these parties had looked at their work and at that of others in the right way, all this bickering would not have been. It would almost appear as if many consider their photographs as an end rather than a means to an end, and as if all that is expected of the spectator is that he should admire the skill of the worker as shown in his work; sometimes even it appears to be the *author* of the work who expects to be admired. Only the other day this was strongly impressed upon me. A youthful photographer was pointing out the beauties of what he considered a most successful picture, which he had just finished, to one of our oldest photographers, saying how he had been advised to place a figure at such a spot, but did not, because and because, seeing the old photo-

grapher smile, he stopped in his oration, and, I hope, received a useful lesson when the old one said: "Pardon me for smiling, but I was thinking of a whipping I once got for falling into a horse-trough the very image of the one you have there." That old photographer knew how to look at photographs, for he was able to make them speak to him and recall to his mind bygone days. The person who looks at a photograph as a complete picture, unable to say anything about anything except the facts which existed at the moment of exposure, does not see very far. You may contend that, if this is true, it will depend more upon the spectator than upon the photograph, for what will give pleasure to one will say nothing to another. To be sure, if the spectator is blind to everything except the mechanical part of the work, the loss is his alone; but he need not, as he often does, call attention to his own ignorance by denouncing a picture a failure because his mind happens to be blank except so far as a knowledge of a certain kind of mechanics may go.

If a photographer thinks he can tell his tales better by making his works microscopically sharp, let him do so by all means; if any one's hobby is the study of mosses and fungi, no pinhole or spectacle-lens view will remind such an one of the happy days he has spent in poring over over damp walls in musty nooks and corners. To some an extremely sharp picture may be positively painful, for it will perhaps disturb and break the train of thought, whereas a less-defined one would allow the mind to wander at its own sweet will. At the last exhibition of the Photographic Society, the hanging committee, the secretary, and the judges had the opportunity of studying a few works which the rest of the world were not allowed to see. I don't allude to those which were hung on the floor, and afterwards consigned to the cellars, but to a small collection of pictures by the worthy President of this Convention. Among them was an almost ideal photograph. I don't mean that it was so uncertain and undefined that it could have represented anything the spectator might have been pleased to wish, but it was just enough to start the mind along a pleasant channel. The foreground did nothing more than carry the eye to the principal object, and when it got it there the eye was politely asked to take a seat, and the mind then began to entertain the spectator, and picture after picture were put before him; one heard the wind blowing and whistling through the mill sails, then it almost died away, only to come again in louder and louder gusts. Now the miller and his man come out and look anxiously, first at the yellow sky, and then at the wands, from which they take in nearly all sail. Yet the big arms rush round at a fearful rate as the sky gets darker and darker; what an enormous size the mill looks—did you ever go underneath a mill's sails in the dark? What terrible things the arms are—they are more like a nightmare than anything real, as they come down threatening to crush you at every turn, yet never getting any nearer. Then, perhaps, you awake from your dreams, only to find yourself inside the mill on a bright summer's morning, where the snowy whiteness is but little less dazzling than the sunshine outside. You notice how spotlessly clean the floors are polished by an unending stream of golden grain; your nostrils drink in, with infinite delight, the scent of newly ground wheat. Perhaps the miller weighs you in the big, old-fashioned flowry scales, in which have been weighed, in good years and bad, the daily bread of the whole village. All this, and much more, did Mr. Davison's simple photograph say. Had it been taken by one of the cast-iron school, the same pleasant train of thought might have followed, if (mark the "if," if you please) one could only have kept at a distance of ten yards; but where is the man who is content to look at a photograph from this distance? No, it would have drawn us nearer and nearer, and every step would have disturbed the train of thought by forcing other subjects forward. Most likely the excellence of the lens would have been impressed upon us, and, once started on such a subject as cameras and lenses, good-bye to all pleasure.

You may think a windmill is a very suggestive subject—almost alive, as it were—and that it is only natural that it should have a story to tell. Very well, then, take photographic portraiture, or likeness-taking, as it used to be called; which are the successful portraits? Those which are most beautifully posed, most brilliantly lighted, and most elegantly retouched? Not a bit of it. The best portraits are those which remind us in the happiest way of the originals. Those sitters who go to be taken only to please themselves are invariably disappointed, and "serve 'em right;" for who, in their senses, wishes to be reminded of themselves? Or take views for a change. Why do people buy local views? Are they allured into spending their money because they are offered such exquisite examples of photographic art? No; all the tourist wants is something to remind him of the places he visits, something to strike a note in his memory. A few years ago I took a view, but somehow or other it did not sell at all, though it was as clear as the most fastidious could wish for. No; the view which sold was taken by the other man, though he ought to have been ashamed of it, for the grass was black, and his whites were white without any mistake. But his prints sold; do you know why? At one corner of his view was a whitewashed public-house. I learned afterwards that visitors called there to refresh. My view did not include that ugly public-house What I gained in artistic excellence I missed in sentiment and £ *s. d.*

There is another class of work which should certainly be able to speak. I mean subject or *genre* pictures; but these sometimes fail to appeal to anything but the spectator's sense of humour, so narrow is the line which divides the sublime from the ridiculous.

Turn to whatever branch of photography we will, it is hard to find one that does not provide ground for our airy palaces. You have all heard of the man who had been so badly brought up that

> "The yellow primrose by the river's brim
> A yellow primrose 'twas to him,
> And nothing more."

Somewhere on the walls of this room you will find a photograph of some animals—sheep and lambs. Now, this little photograph will most likely say to you what the yellow primrose ought to have said to the unfortunate man. It will remind you of the days when you were young and innocent as the lambs; it will remind you of successive spring-times, of the birth of many happy years. Young lambs always remind me of a photographer I knew when a boy. He was always singing—

> "If I'd as much money as I could tell,
> I wouldn't go crying, 'Young lambs to sell!'"

He had, like many of us, mistaken his vocation, and was consequently miserable.

If possible, whenever you look at a photograph, try to forget the photography. An architectural photograph will preach no end of sermons in stone to one who is well versed in the history of architecture, but to one who knows nothing of this art it will only tell of small stops, wide angles, and the like; it will supply him with less mental food than the view of the lambs would to a man who had never known the country, to whom sheep and lambs only meant mutton chops and lamb and mint sauce.

No doubt you are thinking, Who do you expect has time nowadays for all this dreaming, and will be saying that you want your pictures ready made without being at the trouble of making them for yourselves. If these are your thoughts, I am afraid you find the world a very hard place, for, if you take away the "make-believe" with which life is coloured, you must make existence almost unendurable.

Those among you who are unable to agree with what I have said will, I think, at least admit that it is better to take your photograph first, and then build your ideal on it, than to raise your ideal and then expect to be able to take a photograph to come up to it. I will, if you will allow me, give you an example. A customer of mine wanted his shop-front taken. By the way, shop-fronts are about the only things the amateur has left for us poor professionals to take. Well, I took the shop-front, but it failed to please. Why? Because my customer expected the photograph to rise as high as his imagination did. When I asked him to point out the faults, he said that, in the first place, the young lady looking out of the window was too short and fat, not tall and graceful, as she should have been. Secondly, a wax figure he expected next week for the window did not show in the photograph; but his principal objection was that a gilded sky-sign, which he intended having put up next winter, was not in my picture.

May I say that a photograph gives us the naked truth, which has to be clothed by the imagination.

The annual Convention dinner was held on Friday evening, and was the most successful that has ever yet taken place. There were many ladies present. Mr. Davison, in the chair, was supported on either side by Miss Barnes, Miss Carey, Dr. Mitchell, and Messrs. Bothamley and Cembrano.

The toast of "The Convention" was responded to by Messrs. Cembrano and Barclay, the hon. and local secretary. Mr. W. H. Walker proposed "The Ladies." Miss Barnes responded. The toast of "The Photographic Press," given by Mr. Wm. Lang, jun., was acknowledged by Messrs. Taylor, Sturmey, Wall, Welford, and Ward. Mr. Bothamley gave "The President," who responded. The songs, recitations, sentiments, and anecdotes were numerous, and were contributed to by Miss Barnes, Mrs. Mason, Mrs. Werner, Mrs. Warneuke, Dr. Mitchell, Messrs. Joseph Cox, Bridge, Crooke, Mason, Werner, Welford, R. Cranston, H. M. Smith, T. Scott.

The party present numbered about a hundred, and the utmost geniality prevailed.

The excursions were well attended, and the weather being fine, innumerable pictures were taken, a noticeable feature being the number of ladies who carried and made good use of hand cameras.

On Saturday morning an open meeting of the new Council was held, Mr. Bothamley presiding. The Hon. Secretary (Mr. F. P. Cembrano), in making his financial statement, stated that from the members' subscriptions they had got so far 59*l.* 5*s.*, and from advertisements 16*l.* 5*s.* The local expenses amounted altogether to 40*l.* 14*s.* 3*d.*, and he hoped there would be a small surplus. After a little discussion, a motion, proposed by Mr. G. W. Webster, Chester, and seconded by Mr. George Mason, Glasgow, was adopted, authorising the Council in future to take such steps as might be necessary to make the Convention self-supporting. Votes of thanks terminated the proceedings.

The election of the president for next year was then proceeded with, and Mr. George Mason, of Glasgow, was unanimously elected to that office.

It was felt that the Convention was very deeply indebted to the kindness of many members of the Edinburgh Photographic Society, several of whom were most assiduous in their attention to their visitors.

We have seen proofs of the large Convention group, taken by Mr. Alex. Ayton, jun., and the smaller one, by Mr. John Stuart. Both are excellent.

Our Editorial Table.

The Practical Index of Photographic Exposure.

By A. R. Wormald, Sutton, Surrey.

Mr. Wormald's little pamphlet has now reached its seventh thousand. This edition has an appendix on the speed of plates, as indicated by number of times, sensitometer numbers, &c., in which, *inter alia*, the author casts doubt on the value of sensitometer numbers, as adopted by some plate-makers. Tables of the probable average speeds of some of the principal plates are given.

Mr. Wormald also sends us his cheap tripod head. This consists of a wooden triangle, on the under side of which are attached three revolving rollers, into which three very light legs are screwed. The head and stand cost (for half-plate) 3*s.* It is a marvel of cheapness.

Guenther Wagner's Transparent Albumen Colours.

C. A. Rudowsky, 3, Guildhall-chambers, E.C.

Mr. Rudowsky has shown us several photographs most skilfully coloured with the above preparations, the advantages claimed for them being that they are liquid, ready for use, need not be rubbed on a palette or diluted with water; work satisfactorily on all kinds of glossy photographic or photo-lithographic papers, are perfectly transparent, dry with a gloss, can be applied without difficulty, have a high degree of permanency, and are not affected by the burnisher or by the application of collodion. The colours are equally available for lantern slides and transparencies, and, from the specimens submitted to us, we have no doubt that most artistic effects can be produced with them. They should be welcome to amateurs.

For spotting purposes, Mr. Rudowsky also has Wagner'e albumen retouching medium in a variety of photographic tints. These can be applied in the finest spots as well as in the most delicate lines. They will, by themselves, or mixed with one another, yield every hue desired, and will stand the hot burnisher. For professional use these media should prove a great boon, and only require to be known to secure appreciation.

Coloured Photographs on Silk.

Mr. C. H. S. Schultz, of 16, Haupstrasse, Schöneberg, Berlin, who is at present in this country, has shown us specimens of coloured photographs on silk, produced according to a recently patented process. The silk, which is of a special nature as regards its translucency and texture, is sensitised and printed in the ordinary way, a rather weak print being aimed at. It is then coloured from the back with dry pastel colours, and the resulting pictures are of a most artistic description, especially in the rendition of ladies' dress fabrics, &c. We can conceive that such colour photographs would be very popular, and it is in its favour that the process is easily worked.

The "Sandell" Plates.

R. W. Thomas & Co., Limited.

We recently made some trials of the Sandell plate ("General" rapidity), and can therefore speak from actual experience of the value of the claims made on their behalf. In cases of considerable over-exposure purposely given, we found that by removal of the surface veil by ferrid-cyanide excellent printing negatives were easily to be obtained, whereas, in ordinary cases of over-exposure, it would have been difficult, if not impracticable, to get results equally as good. The "Sandell" plates should render the plate-user practically indifferent to the terrors of over-exposure. Their halation-preventing properties are also conspicuous. Our exposures included tree tops on a background of bright sky, against which the leaves and branches were sharply defined without exhibiting the least encroachment of the lights. But what perhaps impressed us as much in favour of the "Sandell" plate as anything else was the extreme ease with which, for such a rapid plate, the fullest density could be obtained with a normal and yet very rapid exposure.

Sun Pictures from Many Lands.

London: Hazell, Watson, & Viney, Ld. Office of the *Amateur Photographer*, 1, Creed-lane, E.C.

This elegant volume is the outcome of one of those "Holiday with the camera" competitions which are so popular among the readers of our contemporary. The literary matter is derived from numerous descriptions of holiday outings, in which the respective authors have contrived to condense a great deal of readable information of a topographical, historical, and photographic nature. Several of the essays are illustrated from photographs by the authors in a manner which the editor claims as a novelty in this country, a great many well-selected and charming collotypes in various tints being interspersed throughout the text. A couple of excellent detached Woodbury-gravures are also given. Collotypic printing in "Sun Pictures" reaches a high level of excellence, the volume, as a whole, being most creditable to publishers, printers, and editor alike. An index of contents, however, would have been welcome.

RECENT PATENTS.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

July 14,—Mr. Beckett in the chair.

Receipt of a copy of a work on *Bromide Enlarging*, sent by the Fry Manufacturing Company, was acknowledged.

Loss of Density in Fixing.

Mr. J. S. Teape said that many people ignored the idea that there was any loss of density in the fixation of a negative, and he would like the opinions of others on the subject. He himself found that, take it generally, there was a very considerable reduction. Some negatives might have a pretty apparent reduction of the image when the small amount of light in the dark room prevented them seeing the actual density. For the purpose of deciding the point, he had carried out an experiment. He had cut a plate in halves, exposed the halves together to a transparency, and developed further than he should have developed for ordinary purposes. Having fixed one half, he washed the developer from the other half, and examined both in daylight. The half which had been fixed would have been a fair printable negative, but the unfixed half was so dense that he could only just see the image. Upon fixing it out there certainly was a considerable reduction of the image.

The Chairman observed that when he was working with negatives by a weak light, in making copies or enlargements, he found that he had to keep the developer on for a much longer time in order to get density.

Mr. W. E. Debenham thought the idea that there was any reduction of density was a mistake. There might be a great apparent reduction, simply from the amount of semi-opaque matter in the film, which alters the light so much in its passage through as to give the idea that it was a much denser negative than it was; but as soon as the bromide was removed, more light got through the film, and one could see the proper density. The negative would appear much denser in a weak light than in a bright light.

Mr. P. Everitt said the difference in the thicknesses of films might account for the apparent loss. Again, was metallic silver soluble in hypo, so that the negative might be supposed to be reduced in the fixing?

The Chairman observed that he always had a loss of density in weak light.

Mr. Debenham asked what the chairman meant by weak light, and thought that he was confusing two things: one was weakness of light where the light was proportioned throughout the whole scale, as in making a transparency in the brightest summer or winter. Then, as to weak light with a snap-shot, the difference between the highest lights and deepest shadows not being so marked, there was no difference when the light was proportioned throughout. Given a proportionate exposure, the ultimate result is the same. It had been said that a small stop was supposed to give a weak image, but he had never been able to find any difference in the results.

The Chairman said with a snap-shot they perhaps got a poor exposure, and in the winter they would have the same thing very much alike.

Mr. Debenham said that in that case it would be better to say the loss of density was noticed with under exposure.

The Chairman substituted the term insufficiency of light.

Mr. Teape said that this was only one phase of the matter. Another was where proper exposure was given. The question was, What was the cause if the loss existed?

Mr. Everitt believed the "loss" to be due rather to the nature of the film than the action of the fixing bath. He had noticed it with plates made by himself which had a large proportion of iodide of silver. The yellowness of the film, due to the iodide, added materially to the density of the image.

The Use of Bromide in Development.

The Chairman asked what was the practical use of bromide in development?

Mr. Debenham said it enabled one to develop for a long time without obtaining fog in the shadows, and might enable one to get greater density, and also a brighter image throughout, where, in the absence of bromide, there would be veil.

The Chairman had seen it stated in one of the journals that a ten per cent. solution of bromide destroyed the latent image.

Mr. Everitt suggested that a little ferridcyanide might have been present, and that would destroy the image.

The Chairman said if the statement he had referred to was correct, the bromide must have the same effect in the developer.

Mr. Teape found at the start of the gelatine process that he was continually getting over exposure, and used to commence development with a solution of bromide alone, adding the pyro drop by drop, but he had never experienced the effect referred to.

The meeting shortly afterwards closed.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

HELIOCHROMY.

To the Editor.

Sir,—I see, from Mr. Ives's reply in your issue of July 15, that he is personal and suspects my truthfulness. I cannot as a gentleman follow him in that way.

If he has any real official document to prove the truth of his assertions against me, he can publish it. I don't fear it. The photographic world knows me longer, and perhaps better, than him.

It is very singular and significant of his style of argument that he again asserts that my principles were "not in accordance with the Young-Helmholtz theory" in spite of Helmholtz himself, who acknowledged my heliochromic prints, and said that they were in accordance with his theory (*vide* the Journal, p. 446). I am sure that the world will believe Mr. Helmholtz in preference to Mr. Ives.—I am, yours, &c.,

Berlin, July 17, 1892. Dr. W. H. Vogel.

COPYING PHOTOGRAPHS.

To the Editor.

Sir,—I have not observed in the numerous exposure tables compiled for photographers any special instructions for copying engravings and photographs, especially platinotypes. We so often wish to reproduce a good photograph, either of the same size as the original or reduced, in order to give copies to friends, &c., that such instructions would be considered a boon by amateurs. Neither is it at once apparent how the calculations are to be made. When the normal focus of the lens becomes much longer, as it does in copying, all the measures marked on the lens, mount, &c., are in such cases quite useless; and it becomes necessary to remeasure the diameter of the stop used, and the new distance from the stop slit the screen in each case, in order to calculate the intensity of the light.

Then, again, I think, in copying a monochrome such as a platinotype or engraving, other conditions of development and intensification obtain than in the case of an ordinary landscape or portrait, and, in order to obtain the best results, a special table and special instructions for the use of copyists would be of great advantage. Do these already exist in a separate form?—I am, yours, &c., Ethel Constance May.

July 19, 1892.

CORRECT EXPOSURE.

To the Editor.

Sir,—Mr. Michael quite ignores the concluding paragraph of my last letter, and it is very difficult for me to believe that he wrote the first and third paragraphs of his letter, appearing in your issue of last week, in real earnest. If he did so, I will endeavour to explain myself to him more clearly, using his own example.

With two lenses, one of eight-inch focus, and one of four-inch focus, used with an identical stop of one inch in diameter, the number of rays of light from any unit of surface of the landscape which pass through the stop will, in the case of both lenses, be the same, for the area of the stop is the same. But, as the image formed by these equal number of rays of light will, in the case of the four-inch lens, be only a quarter the area of that formed by the eight-inch lens, the number of rays of light which fall upon a unit of surface of the plate will, in the case of the shorter-focus lens, be four times greater than in the case of the longer-focus one, and the effect on the plate will *not* be the same in both cases.

If, instead of a stop of the same area, one of the same *relative* area had been used, the number of rays of light falling upon a unit of surface of the plate would have been equal in both cases, as I pointed out in my last letter, and the effect on the plate would have been the same.

If Mr. Michael has still any doubt on the subject, let him prepare a screen, ruled into equal squares, which will represent units of surface, and photograph it with his two lenses from the same stand-point, using, first, stops of the same *absolute* area, and then stops of the same *relative* area, and I think that he will find that the results bear out what I say.—I am, yours, &c., E. Collier Green.

Derby, July 17, 1892.

PLATINUM RESIDUES.

To the Editor.

Sir,—I send you four platinotype prints—copies of paintings of Tasmanian scenery, printed on Steinbach plain photographic paper and sensitised with two drachms of platino salt to three ounces of iron solution, two of B and one of A.

I have just finished a large order of 8000 copies of same, and have kept the developing and acid bath. Would you kindly inform me what is the best means of throwing down the platinum in the said bath, and how to dispose of it—that is, would it be advisable to sell it in the colonies, or send it home?

Also, can you inform me who are the best authorities on collotype and photo-mechanical printing, and where they are to be obtained.—I am, yours, &c., C. Scott,

Hobart, Tasmania, May 31, 1892. *Government photo-lithographer.*

[The platinum pictures our correspondent sends us are truly admirable, the gradation of tone being remarkably well rendered. Information as to the recovery of platinum residues is given in the course of a leading article in the present number of the Journal. Probably, to a beginner in the practical study of process work, Mr. W. K. Burton's book on *Photo-mechanical Printing* (published by Marion & Co., Soho Square, London) would prove most serviceable.—Ed.]

COATING PLATES.

To the Editor.

Sir,—I cote my own Plates; Sum i get to thick and sum to thin; i thought of geting a Silver Spoon and Put it on and Spred it over with a Pice of glass tobing; will the Silver Spoon inger the emulshon?—I am, yours, &c., Ameture.

July 19, 1892.

[No, good "Ameture," a silver spoon will not injure the emulsion. Utensils of silver are extensively employed in commercial emulsion making.—Ed.]

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

Arthur Frederick Winter, Preston.—*Portraits of H.R.H. Duke of Edinburgh, Captain John and Mrs. Humber (Mayor and Mayoress of Preston), Master Humber, Earl Latham, Hon. W. G. Colville, and Lieut.-Colonel A. M. Moorsom.*

Cromwell Hall Warren, Bristol.—*Photograph of the refreshment building and broad walk at the Zoological Gardens, Clifton, Bristol.*

RECEIVED.—J. H.; J. S. Gladstone; and others.

MIA.—The Scotch and Irish Oxygen Company, Polmadie, Glasgow, supply gas cylinders.

G. E. T.—You might try a dilute solution of cyanide of potassium, and, if that does not remove the stain, you may conclude that the case is hopeless.

OXALATE.—Messrs. Barnard & Son publish a work on the crystoleum process, and supply all the materials for it. Their address, we believe, is Berners-street, W.

SODIUM says he is much pleased with the Ilford printing-out paper, and asks if it would be possible to enlarge upon it, using an enlarging lantern and the limelight.—No; except with such an exposure as would make the thing not worth the trouble.

T. SIDEY.—The fault of the pictures is that they are, like many amateurs' hand camera pictures, very much under-exposed. Either the shutter was too quick for the plates or the plates were too slow for the shutter. With the class of subjects enclosed an excessively quick shutter was not necessary.

DUBLIN.—The appearance described is due to the balsam with which the lenses are cemented. By warming the combination the lenses may be separated, and the old balsam cleaned off with turpentine, and recemented. Perhaps, if you are not familiar with the manipulation, the best way will be to get a practical optician to do the work.

A. W.—In intensifying carbon transparencies with permanganate of potash the strength of the solution is of little importance, though it is not advisable to use it too strong. The same end is attained by using a weak solution as a stronger one; it is only a question of time. From ten to twenty grains of the salt to an ounce of water is a good proportion.

R. BISHOP.—In marking the pictures "copyright" when they are not registered according to the Act, you are acting illegally. You have no right to claim as a monopoly what you do not possess. For example, if you were to mark a thing as "patent," although you may have provisionally protected the invention, but have not completed the patent, a penalty is incurred.

C. CURTINS.—The excellence of the reproductions of painting of Continental production, seen in the shop windows of London, is not due to any superiority in the light in which they are made, but to the skill of the operators. As a rule, the wet-collodion process is used for this class of work. We need scarcely say that full advantage is taken of orthochromatic photography.

THOMAS EVANS (Cardiff).—We have no knowledge of the person of whom you bought the hand camera, but it appears to us, that as, according to his letter, he states that a lens of four and a quarter inches focus would suit it, and you find that it does not, you have legitimate ground for complaint. Consequently, we are of opinion that you can legally compel him to return the money.

A. ALEXANDER asks which process requires the more expensive plant for its working, the collotype or the Woodburytype?—The Woodbury process is the more costly, on account of the hydraulic press with the planed steel plates, and the rolling press and plates necessary for the preparation of the paper. With collotype an ordinary typographic press, or a lithographic press, is the most costly thing required.

S. A. J.—There is no school in London, or elsewhere so far as we know, where posing and lighting the sitter are taught. The knowledge you have acquired, as an amateur, in six months will, we imagine, avail you but little in securing an appointment as operator in a first-class London establishment. Skilled operators of many years' standing are, unfortunately, only too plentiful to leave much chance for novices.

SOLIDS.—If you have the chloride of gold in solution, or, as you term it, in a liquid form, all you have to do to get it into a "solid form" is to place the solution in a Berlin evaporating dish on a sand bath, and apply heat until the water is evaporated. If, as you say, you have got rid of the acid, it will be well to add a small proportion of hydrochloric acid before commencing operations, and thus avoid decomposition of the salt.

B. JACKSON.—The "steel facing" of photogravure plates is by no means a difficult thing to those who understand the work. But our space will not admit of giving full details of the work, as it would involve writing a treatise on electro deposition. Besides, probably not half a dozen readers are interested in the matter. Our advice is, send the plates to one of the firms who make a speciality of "steel facing," particularly as you have "only one or two to do now and then."

COL. A. (India).—From the description of the behaviour of the paper, we imagine you have over-dried it. Bear in mind that a certain amount of moisture is necessary in the paper while printing, otherwise it will not tone readily. Of course, if the pads and the backs of the frames become abnormally dry, they will absorb moisture from the paper, which will practically become equivalent to over-drying the paper.

A. A.—In crossing the French frontier from Germany you may possibly meet with a little difficulty with the exposed plates, as you do not speak French; but if you provide yourself with a passport from our Foreign Office, and are courteous to the Customs officials, the difficulty will, no doubt, be surmounted. Without any suggestion of "bribery or corruption," we may mention that a franc or two often overcomes difficulties in foreign parts.

B. AND D. (Swansea Valley).—The length and width of the studio will depend entirely upon what you wish to do in it, and this you do not say. A length of twenty-five feet will enable full-length portraits to be taken, of the cabinet size, with a lens of the most suitable length of focus to use. The width may be from ten to twelve feet. If you wish for a studio for groups, &c., the length and width must be proportionately greater. If the studio is wanted only for amateur work, probably one of smaller dimensions will suffice. If you have a choice of positions, as from your letter we surmise you have, let it run from east to west, so that the light is admitted on the north side the south being opaque.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—July 26, Technical Meeting. Subject for discussion, *Modern Developers.*

MAJOR LEONARD DARWIN, formerly a member of Council of the Photographic Society of Great Britain, was among the successful parliamentary candidates at the recent general election.

PHOTOGRAPHIC CLUB.—July 27, Open Night. August 3, Outdoor Experiences. July 23, Outing to Oxted and Edenbridge. Train from Victoria at thirty-five minutes past two; from London-bridge at twenty-five minutes past two.

MR. JAMES CADETT informs us of the termination of his engagements, and his resumption of the manufacture of dry plates under his own name. He has associated himself in partnership with his brother-in-law, Mr. Walter Neall. The "Cadett" plate of Messrs. Cadett & Neall will be placed on the market on the 1st of August. The firm's works are situated at Ashtead, Surrey, and they have decided to adopt the Hurter & Driffield standard for the testing of plates. Mr. Cadett's long experience in the art of plate-making should stand the young firm in good stead in its venture. Three rapidities of plates will be made, viz., "Lightning," "Ordinary," and "Lantern."

THE POTSDAM OBSERVATORY.—In his recent inaugural address to the Berlin Academy, Professor Vogel gave an account of the important work cut for the Potsdam Astro-Physical Observatory, of which he is the head, during the next ten years. The gist of his address was as follows:—It is well known to those acquainted with the subject how greatly astro-physics, and especially the spectrum analysis of the fixed stars, have been promoted by the application of photography. When the same optical means are used, spectrum photography enables one to make measurements twenty times more exact than those made by direct observation through the telescope; and, as a result of his investigations, carried on for several years, by the new method, Professor Vogel drew up, in the beginning of this year, a catalogue of the motions in the vision-radii of fifty-one of the brightest stars of our sky. One of the main tasks of the astronomers of our time is to extend this catalogue to the utmost limits the most powerful telescopes admit of, so that it will comprise about five hundred stars. Professor Vogel has good reason to hope that the improvements of the instruments of the Observatory necessary for this purpose will be granted him ere very long. Besides their main purpose, which is the enlargement of our knowledge of the motions of the fixed stars, these spectrographic investigations have led to the demonstration of a class of double stars, hitherto only assumed to be such, the peculiarity of which consists in the extremely small distance between the components, so that contact of their atmospheres seems almost inevitable; and no optical apparatus powerful enough to render the components separately visible can be imagined. Certain relations of these systems to the so-called new stars, and especially their comparative frequency, seem to indicate that these close double stars play a far more important part among the fixed stars than has till lately been supposed, and the investigation of these relations therefore promises to be of great importance. Among the fifty clearest stars of our sky, four such stars are already recognised with certainty.

*** *Owing to the pressure of Convention matter, we have been obliged to hold over several letters, Society reports, and other communications. These will be given in our next.*

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1682. Vol. XXXIX.—JULY 29, 1892.

AN IMPROVED METHOD OF TREATING RESIDUES.

The time-honoured method of adding salt—common kitchen salt—to the washings from silver prints is always difficult to displace by improved methods; still, as the ever-increasing pressure of competition causes every professional photographer to seek means of increasing his income, it may yet be that, if he see any distinct gain, he will throw aside prejudice, and take up new plans promising gain. At the outset we may say that chloride of sodium is a very unsuitable precipitant for two potent reasons. In the first place every printer of experience knows that, when the silver is precipitated in the ordinary way, a very long time has to elapse before the last traces of chloride subside; it is necessary to have several vessels to be used in succession, so that the one first filled may have cleared sufficiently to be ready to empty by the time the rest are full. If this be not done, the liquid run off is "milky," in other words, contains a quantity of finely divided chloride of silver in suspension, and this goes down the sink and is wasted. Secondly, though the liquid may be quite clear, there is yet a considerable waste; for solution of chloride of sodium dissolves an appreciable amount of silver chloride, and to the extent of this solubility must loss accrue. If any one entertain any doubt on this point, let him very carefully filter a portion of the clear liquid standing over the precipitate, and add to it one drop of the solution of liver of sulphur, which he uses for throwing down silver from the hypo. The considerable discolouration produced is irrefragable evidence of the presence of silver.

Both these objections may be removed by using hydrochloric acid. The impure acid—the muriatic acid of the dry-salter—will suffice. It does not dissolve the silver salt, and it causes the precipitation to be more speedy, or perhaps we should say less slow, in falling, and is thus decidedly a gain in material and in time.

But even with this precipitant there is delay, and, where space is of importance, it cannot but be that some silver is wasted through insufficient time being allowed for subsidence. We have, therefore, been making a series of experiments bearing upon this point, and have devised a method which seems to be all that can be desired. Starting with a process employed in metallurgical operations, we first tried the effect of precipitating the silver as a bromide; but, try it how we would, no benefit resulted in any way commensurate with the increased expense this more costly salt involved.

Our next plan was to add to the washings some substance which would cause a more speedy falling of the chloride. After numerous failures, particulars of which need not be here recounted, we brought into use a soluble lead salt, which might be precipitated at the same time as the silver, and perhaps, by virtue of its great specific weight, assist the silver to fall by enveloping the particles of silver chloride. This plan met with complete success. So far our trials have been merely on a laboratory scale, and thus not with a large bulk of liquid; but there is no reason to doubt that, when put into actual practice, it will act in a precisely similar way.

Taking a quantity of washings obtained from prints to cause the laboratory conditions to, as nearly as possible, resemble printing-room work, and, dividing it into a number of portions of equal bulk, we placed them in a series of test tubes. The first experiment was a mere tentative trial, but its success was evident. A few drops of solution of lead nitrate were added to one test tube, and the precipitant added, a second tube having the same treatment, but with the lead left out. In number one tube the precipitate all sank to the bottom and left a clear liquid in less than a minute, while the second tube was milky half an hour afterwards, and no doubt would take a day or so to become quite clear. We next tried the effect of varying quantities, and we found that there was no gain whatever in increasing the proportion of lead salt beyond a certain small proportion. This proportion, as near as we can judge, would be about one-fifth of the silver salt present.

Next we ascertained the best form in which to add the chloride. The action was so prompt that it was needless to experiment again with bromides. The result was that, though hydrochloric acid was very quick in action, the ordinary table-salt solution was still better. It was then desirable to see whether a more easily obtainable lead salt—the acetate—would answer. It was quite equal to the nitrate.

We were thus in a position at once to formulate a method for practical use. To each jar of print washing—say, of ten gallons—add a quarter of an ounce of acetate of lead—sugar of lead, it is commonly called—and, when completely mixed, add the usual chlorine, either as "salt" or as "muriatic acid," stir for a little time, and allow to subside.

We are hoping that before long we may be able to say how the plan works in practice on a large scale, for Mr. Watmough Webster, who joined us in these experiments, has promised to introduce the method into his daily practice, for a time at any rate, and report the practical results attending what may be termed the lead method of precipitation.

THE ALUM AND HYPO FIXING BATH.

Interest has been recently revived, in connexion with some of the commercial "printing-out papers," in the almost-forgotten combination of alum and sodium hyposulphite, or thiosulphate, introduced many years back with a view, as was supposed, of securing in the one solution the hardening effects of the one and the fixing action of the other. It is at least ten years since this composite bath was first publicly mentioned at a

meeting held in the Hall of the Society of Arts, and it was at once pointed out that, as the two substances decompose one another, there was scarcely any probability of the desired end being attained, since, if the bath were to possess any fixing power, the hypo must be greatly in excess of the alum, which would consequently be totally destroyed or deprived of any action it might possess.

Although the combination was written down as useless, and practically set on one side as a merely fanciful innovation, it continued for some time to keep a slight hold on the public, some of whom claimed for it that, whether right or wrong in theory, in practice it was decidedly superior to plain hypo; and now, at the present day, it is actually coming into use again, under the recommendation of some of the leading manufacturers of gelatino-chloride papers. Under the circumstances, then, it may be worth while to examine critically what the compound solution really consists of.

It is a fact well known to the large majority of our readers that a solution of sodium hyposulphite, even when pure, is of a rather unstable nature, and that it is instantly decomposed by most acids, with liberation of sulphur and sulphur compounds. To avoid the risk of introducing any such dangerous agents into the fixing bath of days gone by, it was the practice with many to render it very slightly alkaline, especially when employed for the fixation of prints, the whites of which, amongst other advantages, were supposed to be thereby kept much purer, while the risk of fading was also considered to be lessened.

In recent years, however, a movement has been made quite in the opposite direction, and it is not long since the photographic world was discussing the merits and demerits, the orthodoxy or otherwise, of the acid hypo bath. As in the case of alum and hypo, there was at once a great outcry that the acid bath was theoretically and scientifically impossible, and could only lead to imperfect fixation and rapid destruction of the images submitted to it. Here, again, practice stepped in, and said that not only was the thing feasible, but that it was a distinct improvement upon the old bath of plain hypo; and, upon examining more carefully into the chemistry of the matter, the "rule-of-thumb" men were found to have reason on their side. If properly prepared—and many different formulæ were published—the bath, when ready for use, contained, besides the hypo, nothing but free sulphurous acid or an acid sulphite; and as this acid, unlike most others, causes no decomposition of the hyposulphite, while it possesses distinct clearing powers on the negative image, an advantage might fairly be claimed for it.

But, after all, many of the formulæ were simply very roundabout methods of simply adding the acid or acid sulphite directly to the bath, for the result was attained by adding other acids, which, by partially decomposing the hypo, liberated the agent required, the process in many cases requiring great care in order to secure the proper result. The alum and hypo bath is, perhaps, another example of taking a somewhat roundabout way of arriving at something like the result aimed at.

As all who have tried it are aware, that upon mixing solutions of alum and hypo a dense precipitate is formed, but the behaviour of the mixed solutions varies very greatly with the conditions under which they are brought together. When concentrated solutions are employed, especially if hot, the mixture almost instantly solidifies into a soft solid mass, from the sudden precipitation of alumina in the gelatinous state; with weaker solutions the combination takes place less rapidly, and the precipitate partakes of a different character, and is more easily separated from the solution. The first thing to be done is, of course, to filter out the precipitate, and the bath is then ready for use.

But now we come to the chemistry of the mixture, which scarcely seems to be clearly understood even by those who recommend the composite bath. From what transpired at a recent meeting, the idea seems to prevail that the precipitation of the alumina is all that takes place, and that a similar result would be achieved with less trouble by simply adding sulphate of potash instead of the double salt that goes by the name of alum. Such, however, is far from being the case, as we shall show, the changes that occur being numerous and complicated.

When a solution of any of the alkaline hyposulphites is heated with a salt of aluminium, the alumina, together with *sulphur*, are precipitated, and sulphurous anhydride is liberated; that is to say, sulphurous acid is formed in the solution, and the hyposulphite is converted into sulphate. Taking the mixture we have under discussion, the following equation shows exactly what occurs:—

$$\underset{\text{2 equiv. alum}}{2\,Al\,K\,(SO_4)^2} + \underset{\text{3 equiv. hypo}}{3\,Na_2S_2O_3} = \underset{\text{1 eq. alumina}}{Al_2O_3} + \underset{\text{1 eq. sulph. of soda}}{Na_2SO_4} + \underset{\text{1 eq. sulph. of potash}}{K_2SO_4} + \underset{\text{3 equiv. sulphur}}{3\,S} + \underset{\text{3 eq. sulph. anhydride.}}{3\,SO_2}$$

Thus we see that two equivalents of alum and three of hypo exactly decompose one another into a variety of substances, and we begin to see that the alum and hypo mixture may possess virtues, though scarcely such as were aimed at by the original introducer of the formula. The changes stated above take place with great rapidity when the mixed solutions are heated, but much more slowly at ordinary temperatures, especially if dilute. One care, then, in using such a fixing bath, should be to give it plenty of time for the decomposition to become complete before filtering it.

It is obvious that the hypo must be largely in excess in order to preserve any fixing power in the bath. When filtered and ready for use, the solution will contain, in addition to the excess of hypo, the sulphates of potash and soda and free sulphurous acid, to retain which as much as possible it is desirable to perform the filtration with as little exposure to the air as can be. Now, the sulphurous acid acts as a clearing agent, while the alkaline sulphates are claimed, with what reason we can scarcely say, to exercise a hardening action upon the gelatine film similar to that exhibited by alum itself. The alum and hypo bath resolves itself, then, simply into another form of the acid fixing bath, with the possible additional advantage of its combining hardening with fixing.

In making such a mixture, it is in every way desirable to know what we are doing, and what is the precise composition of our preparation. From the data given above this is easily done, for, reducing the quantities of the two materials to actual weights, we find by calculation that one ounce of alum will decompose a little more than three-quarters of an ounce of hypo. In making a fixing bath of any given strength, then, it will be necessary to add an additional quantity of hypo equal to three-fourths of the alum employed; and, if this rule be kept in view, it is possible, without altering the fixing strength of the bath, to increase or decrease its clearing and hardening capacities to any desired extent, and so we may convert the mixture into something like a definite formula.

With regard to the hardening power claimed for the neutral sulphates we are personally unable at present to say anything,

but we may point out that one of the earliest remedies for frilling consisted in adding Epsom salts—sulphate of magnesia—to the developer, and to the water in which the plates were soaked. Ferrous sulphate also was proposed by Mr. Kennett a dozen years ago as an addition to the fixing bath for the purpose of *intensification*, though the action was more probably a *clearing* one, by which the colour and contrasts of the negative were altered. In this case too an indurating action has been claimed, and probably with more reason than in the case of the alkaline sulphites; but the clearing action is undoubtedly due to some series of complex decompositions similar in general character to those stated above.

PHOTOGRAVURE AT HOME AND ABROAD.

It is a noteworthy fact that the majority of the mechanical processes of photography are worked more extensively on the Continent than they are at home, and, as some aver, with a certain show of reason, to greater perfection. In support of this idea, it is an incontestable fact that a very large proportion of the photo-mechanical work met with commercially in this country is executed abroad. Notably is this the case, and we regret to have to admit it, with the high-class photogravures, which have practically taken the place of line engravings. When one sees a fine example of photogravure in any of the shop windows of our large towns, the chances are ten, or more, to one that the imprint indicates that it was made on the Continent. We are not here alluding to the reproduction of works of foreign artists, but to those of our own countrymen.

Seeing that the greater proportion of the photogravures from the paintings of the principal artists of this country are produced on the Continent, it becomes a matter of no little interest to inquire why this is the case, particularly when we consider that the processes by which the plates are made owe their origin to this country. Most people would imagine that home photographic engravers would have several advantages over those abroad, in so far at least as British works are concerned. The proprietors of valuable paintings have, very naturally, an objection to their going out of the country, yet for the purpose of reproduction they are continually being sent away. It is true the paintings are sometimes copied here and the negatives only sent. This is, however, exceptional, for the first-class photographic engraver finds it almost an absolute necessity to have the original before him, in order that he may make sure that the colours of the picture are rendered in their true relation into monochrome. Without this being done, the plate would be valueless in the eyes of a first-class publisher, and, what is more, the painter would not sanction its publication.

It is very common, when the alleged superiority of any kind of photographic work over our own is spoken of, to hear the reason assigned for it that the light is so much better on the Continent than it is here. This reason can scarcely be admitted in this instance, inasmuch as, beyond the mere production of the negative, light is not a factor in the case. Of course, it goes without saying that excellence in the negative is an essential, and this brings us to the point, Are Continental photographers more skilful in translating the colours of a painting in a negative, or, in other words, more experienced in orthochromatic photography, than those of our country? It will be remembered that a few years ago a Continental firm reproduced the pictures in our National Gallery in a better manner than they had ever been done before. But since that time the subject of orthochromatic photography has received very considerable attention here. So far as the photographic phase of the question is concerned, we fail to see that the foreign workers possess any advantage whatever over their English *confrères*.

Next to the purely photographic aspect of the work comes the production of the engraved plates. There are two methods in vogue for making them on the Continent. One by forming the plate by electro decomposition upon a grained gelatine relief, the other by etching through a gelatine image on a copper plate with a solution of perchloride of iron. It is the latter process that is in the most general use, as it is also in England. Are the foreigners more skilful in the manipulations, or have they any special method of working that is not known to us? One can scarcely imagine either.

There is, however, another point of importance in the production of a photogravure plate beyond what may be termed the mechanical portion of the work, namely, the retouching of the plate. This, of course, requires a considerable degree of skill as well as artistic ability. If we examine a number of foreign photogravures from different plates, we shall see on some that a large amount of hand work has been expended upon them, while on others there is very little indeed. But, little as there is, it has been introduced with very great discretion, and often only where photography has failed to properly translate the different shades of colour, thus showing that the mechanical part of the work must have been very perfect in the first instance. Have the foreigners any advantage over us in this direction? There certainly is no reason why they should have. The question of printing from the plates hardly applies, seeing that, although the plates are made abroad, a considerable proportion of them are printed here.

One important item for consideration is price. It is frequently said that foreign work is cheaper than English; but this can scarcely be said with regard to photogravure, for the price charged for the highest-class foreign plates is quite as much, if it is not more, than is charged here. Again, when a publisher has paid a large sum, sometimes amounting to as much as "four figures," for the copyright of a painting, the matter of a few pounds in the cost of its reproduction is a secondary consideration to the quality of the result. The reason that has been assigned for the large number of photogravures from the works of British artists to be seen in this country, issued from foreign houses, is that Continental publishers, it is said, will generally pay a higher price for the copyright of high-class pictures than is the case with English publishers.

Whatever may be the reason or reasons, it is a regrettable fact that so much work in the reproduction by photogravure of British artists' pictures is being continually sent abroad for its execution. Particularly is this the case when we consider that we possess equal, if not greater, facilities for doing it at home.

A Photographers' Party for the Chicago Exhibition.—Mr. H. Snowden Ward informs us that he is making the preliminary arrangements for a party of photographers to visit the United States next year, in connexion with the Chicago Exhibition, and solicits suggestions for the success of the undertaking. Several gentlemen have already expressed a willingness to join such a party.

The N. A. P. P.—These are the initials of the National Association of Professional Photographers, of which body several informal meetings were held during the Convention week in Edinburgh, when many matters affecting the well-being of the Association, and through it of professional photographers, were discussed. Mr. T. Fall (the

President) and Mr. H. J. Whitlock (the late President) take a very active interest in the Association, which is apparently drawing to itself considerable support and sympathy. Probably the annual meeting will be held in London next November, when we hope to hear that the aims of the Association are in process of achievement. The Secretary is Mr. D. J. O'Neill, of 47, Charlotte-street, Birmingham, who will be happy to supply all particulars of the N. A. P. P. to those who are interested in it.

The Stops of Front Combinations.—A correspondent writes this week, *apropos* of the employment of the front combination of a compound lens, asking us to indicate the values of the stops when the half, instead of the entire, objective is used, in order to get what is practically double the length of focus. The rule is as follows: Suppose the stop, which is *f*-8, of a six-inch lens be also used when the front combination alone is taken, it is then expressed as *f*-16. If both figures be squared, it will be found that the larger is divisible exactly four times by the smaller, and the exposure has to be increased exactly that number of times. Applying this rule, our correspondent finds reason to complain of over-exposure, and appears to suggest that a shorter one would have sufficed, on the ground that he gave four times what he would have given with the entire lens. Had he made comparative tests on those lines, he would, in all probability, have found that both pictures would have been over-exposed. But this does not affect either the theoretical or practical accuracy of the ratios.

Fugacity of Bromide Prints.—The Indian climate appears to be peculiarly unfavourable to the longevity of bromide prints, the cause of their disappearance being probably due, as was suggested some months ago, to the instigation by humidity of a chemical action in the material of the paper, which converts the silver into a compound that diffuses and disappears in the support. Mr. J. S. Gladstone calls our attention to the circumstance that bromide prints in contact with platinotypes had, after two years, almost disappeared, the platinum pictures standing well and partly printing themselves on the bromide support. The high temperature, excessive humidity of air, and gentle pressure he is inclined to assign as the causes of the disappearance of the bromide prints are, if we remember, those formerly suggested for the phenomenon. The stability of the platinotypes under these conditions has been commented upon before, but we do not remember having heard of the curious fact that such images "printed off."

Fungoid Growths in Lantern Slides.—Mr. Gladstone also sends us some lantern slides with the films partly detached and exhibiting both on glass and gelatine distinctly marked growths of a fungoidal nature. From our examination it would appear as if the glass were the cause of the growth, although one might have conjectured that the gelatine would more likely to have been at fault. Our correspondent complains of some chloride plates which developed black all over, and is of opinion that such plates will not stand the climate. We could conceive of considerable risk in keeping organic chloride, that is, printing-out chloride plates in such a climate, but we are at a loss to imagine why plates of pure chloride should not keep just as well as bromide plates for negative work. Thousands of dozens of the latter are annually exported to India with satisfactory results. We should think a temperature of 90° extremely high for such plates to be kept in, but we have known of instances where a much higher temperature for a period of several weeks has not produced any ill effects on gelatine plates.

Snakes in the Dark Room.—"Z. F. G." writes to the editor of the *Journal of the Photographic Society of India*: "During these hot days it would be well for every operator to examine his dark room before shutting the door for work. A few days ago I went in my room to make some changes, and found a huge snake, not less than seven feet in length, coiled up under the table. Had I gone in to develop, I should have shut the door, and not have known he was there until I felt him under my feet." Our contemporary remarks: "This is seasonable advice for India, and 'Z. F. G.' deserves our thanks for sending it. The other day, my servant, hearing a noise in the waste-water pipe attached to the dark-room sink, began to tap it underneath, when, presently, a young cobra, nine inches long squirmed out of the hole, and from his appearance seemed to demand the reason of all this disturbance, whereupon the bearer resumed the tapping, but this time on the reptile's head, and then brought me to see it. I have a good look round when I enter my dark room." Indian amateur photography is apparently carried on under most exciting and vitalising conditions at times.

CONVENTION JOTTINGS.—I.

The Convention a Great Success.—Now that the Convention is over, we are in a better position to speak of it than in our first article, when it was still going on. It may now be asserted that, in every respect for which the Convention was established, it has not only proved a great success, but has been the most successful of all the meetings since it was first instituted; that, in short, as the Honorary Secretary said at the last day's meeting, just anterior to the formal breaking up, it has "beaten the record."

To what has this been owing? Doubtless to a variety of causes, amongst which may be mentioned the prospect of revelling amid charming, attractive, and historical scenery and places, the unusually great number of ladies present, the excellent weather, and, in a special degree, to the kindness of several members of the Edinburgh Photographic Society, whose goodness of heart and great attention to the visitors will ever live in their memories.

The Excursions.—The excursions were so planned as not to interfere with the more purely intellectual proceedings, and, as a consequence, both were numerously attended. The excursion to Abbotsford, Melrose, and the locality of Sir Walter Scott proved very attractive; and, although personally we could not form one of the party, yet did we count some ten or twelve compartments in the railway carriages comfortably filled. The next great excursion, that to St. Andrews, saw an equal number, and it was noticeable that almost every lady carried a Kodak or hand camera of some form or other. On arriving at the station we were met by Mr. A. Cowan, who (with his family, in which he so recently suffered a severe loss), was at that time a guest of the Provost of the City. The old place (it is but a small and a very quiet city) must have been seriously thrown out of its equilibrium at seeing itself the cynosure of fifty or sixty tripods planted here, there, and everywhere. It is certainly a glorious old city, and is replete with archæological remains. It is full of old buildings and ruins. Originally named Muckross, a cathedral was erected somewhere in the fourth century, and on the union of the Scottish and Pictish kingdoms the name was changed to St. Andrews. As for the priories and seats of learning which were soon afterwards established, there is no need we should go into them, but they must have had lofty ideas of architecture in those days, and certainly they built well. Here preached John Knox in later days, and he must have had a "sweet, persuasive tongue," exceeding even that of Bothamley, ere he could have induced his hearers to lay in ruins the grand old edifices of those with whom he was of a different way of thinking.

Reminiscences of Sir David Brewster.—In still later, and what we may term modern, days flourished Sir David Brewster, who was principal of one of the universities, and don't forget this, O photographers! it was from this place that the Stereoscope, the Kaleidoscope, the *Optics*, and several other inventions and works of that grand old Scotchman were issued. Hence the photographer cannot afford to turn up his nose at St. Andrews. Oh, what exposures were made that day! It was an *embarras de richesses*. But when the old castle, perched on a jutting prominence in the sea, was discovered and appreciated, then did every lady and every man begin to look anxiously to the numerical state of his reserve stock of plates, for surely here was subject for exposures "galore." The poor old castle was stormed as it had never previously been, and well did it deserve such consideration. This fortress, the guide-book tell us, was founded about the year 1200. James III. was born in it.

Cardinal Beaton resided in it, and, being afraid of the fury of the people after he had cruelly executed George Wishart, a celebrated reformer, in front of it, strengthened it with a view of making it impregnable, yet therein was surprised and assassinated. Our outfit on this excursion was a stereoscopic camera, and, after bagging many attractive pictures and exhausting our plates, we joined the legitimate return party, leaving behind some twenty or thirty others who thought the afternoon's sunshine too good to be wasted, and who returned to Edinburgh a few hours later.

Edinburgh Photographers Past and Present.—We were disappointed at not seeing at the Convention some of the members of the old and extinct Photographic Society of Scotland. Perhaps they are now, like Brewster, the President, all dead. This, we are glad to say, does not apply to Mr. Kinnear, the whilom Secretary of that body, who, in these days of summer travel, might possibly have been touring elsewhere. The privilege, however, of seeing and fraternising with Mr. R. H. Bow, C.E., one of the early members of the Edinburgh Photographic Society, was not denied us. This gentleman, before some camerists of the present day were born, had made a deservedly high reputation by his papers and articles on Photographic Optics, and we know that these works—not ephemeral, but for all time—will long survive him after he has been "gathered to his fathers." Edinburgh has reason to be proud of such a man. We know whereof we speak.

ON THINGS IN GENERAL.

THERE must be something wrong about the Convention; a very great authority wrote it down; it was to be a lamentable fiasco; yet, if reports are to be credited, never has there been so successful a meeting. Moral: Never prophesy unless you know. And what a success it has been! Our brethren across the border have shown us before how to do things, and they have repeated the lesson with variations. Perhaps more than any causes the presence of the softer element has had a large share in popularising the meeting. While on former occasions there have been a few ladies who have, in traditional phraseology, graced the Convention by their presence, there can be no doubt they felt like fish out of water—gold fish, it may be, but, nevertheless, feeling *de trop* in almost all senses. But at last they have become a constituent part of the gathering, and no Convention will be complete without them. The dinner too. Ladies at a dinner! I can safely vaticinate here; this will not be the last Convention dinner at which they will be present. Their voices, both in speech and song, were felt—no other word will better express my meaning—while as to the American guest, Miss Catharine Weed Barnes, she met with a perfect (and deserved) ovation. May this not be her last appearance on these occasions is a wish that will be cordially echoed by every one.

The papers read and the attendant discussions were pregnant with matter for further thought. It is not within the scope of a letter like this to attempt a complete criticism, but a few discursive remarks on topics that have before been touched upon may not be out of place.

Thus, Mr. Arthur Borchett's paper was very interesting, especially when he touched the fringe of the vexed question of the due rendering of objects in motion. His references to the work of great painters were apt and useful. My opinion of Muybridge's wonderful photographs is no secret—useful to the physiologist, useless to the artist, though he told me himself that Meissonier repainted a horse in an important painting more in accordance with the facts than the usual modes were proved to be by the work of the camera. By the bye, the effect upon the public of these and other instantaneous photographs is exceedingly detrimental to the work of the professional photographer. For example, I was recently informed by a well-known artist that, after photographing a favourite horse for one of his clients, with the usual difficulty in getting the position in general, and limbs and ears just as the owner wished them, a great number of plates having been wasted on the work, he was informed that, "Now I would like him taken trotting." It was almost impossible to get the owner of the horse to understand that such work was not of a kind that could be undertaken at a moment's notice, and equally difficult to explain that, if a single picture were obtained, the chances were that the limbs would be represented in a manner that might possibly appear simply ludicrous. The rendering of an agreeable-looking position is practically out of question under average conditions. I use the word "rendering" and not "rendition," as a writer of one of the Convention papers phrased it, followed, alas! by the respected Editor of this paper. If rendition has any meaning at all, which it has not, it could only be in connexion with rending, and not rendering. There, I feel relieved in my mind after that utterance.

Mr. Howard Farmer came out in a new light. We know his ability as a chemist and lecturer, but equally valuable is what he had to say about the commercial aspect of photographic training. It is too true that business ability is usually conspicuous by its absence in the photographic profession. And the more the pity. Who is there that cannot point to men of undoubted ability who have opened a professional studio and gradually come to an untimely commercial end, though their work has been of the highest class and the prices charged not excessive? Some of the most successful professional photographers started life behind the counter of a retail shop, and their experience has served them in good stead. Many of those present at the Convention dinner felt hurt at the President's remark about the Convention Group, which he characterised as the best yet done. We must assume that he alluded to its evidence of the numerical success, and that therein lay its excellence. Otherwise I can only say that there lies before me THE BRITISH JOURNAL OF PHOTOGRAPHY for 1887, in which another Scotch group—that taken during the Glasgow sitting—is *en évidence*, and in no way is it inferior, technically, to the Edinburgh group, though taken evidently under very difficult conditions.

A short time ago a writer to these columns put a query about the new platinotype paper. As there has been no official reply, I may be permitted to say that his is not the only experience of this mottliness; but, when it is remembered that the whole process, as now worked, is quite new, there can be no wonder that some of the prepared paper is not up to a certain standard. As to the excellence and easy working of the new cold-bath paper, there can be no two opinions. It is capable of producing exquisite results, in every way superior to the hot-bath process; but like every other process, and fortunately so, the materials have to be mixed with that essential to successful art, according to Opie—brains.

What a moral the great patent case recently reported in this JOURNAL provides for outsiders. A gentleman conversant with the practical issues of patenting once said, "Getting a patent through and in paying order is all bluffing and tossing halfpence, at the best."

FIERE LANCE.

PHOTOGRAPHY BY RULE.

[North] Middlesex Photographic Society.]

A RETROSPECT.

TEN or twelve years ago, when the gelatine dry plate had finally conquered the prejudices of professional photographers and the ranks of amateurs were being swollen by the accession of many to whom wet-plate photography was unknown except by name, it was often charged against photographers of both classes that their work was largely governed by "rule of thumb"—in other words, that in exposure and development, probably the two most important divisions of photography, success was allowed to depend very much upon pure guesswork, in contradistinction to system and calculation. Those were the days when the rapidity of the plate was generally underestimated; when a frequent if not common method of compounding the developing solution was by shaking an unknown number of grains of dry pyrogallic into an unmeasured quantity of water, and, after soaking the plate in it, adding thereto an undetermined number of drops of ammonia. For rapid exposures, a simple drop shutter, whose rapidity of action could easily be accelerated, but was rarely if ever reduced to arithmetical expression, was mostly used; and albumen paper held practically undisputed sway for contact printing. These broad outlines of early gelatine dry-plate photography may, perhaps, serve to convey some idea of the chief conditions of working which obtained at that period—conditions under which, be it remembered, amateurs as well as professionals pursued photography.

It is, I am sure, needless for me to indicate precisely to what extent those conditions have been changed or modified; for you are all aware that development has been lifted from the low ground of a "rule-of-thumb" operation to the level of a scientific study; the comparative

and particular speeds of sensitive preparations have been made the objects of close investigation and valuable experiments; and mechanical aids to exposure have called an apparently inexhaustible supply of inventive ingenuity into existence—the main and indeed the sole object underlying all those efforts being not merely the simplification of exposure and development, but their reference to pure rule and system. I propose briefly on the present occasion to consider some of the tendencies of modern photography—chiefly amateur photography—for which the application of this scientific method to several of its branches is responsible, and to submit a few reflections of a deductive character thereon.

Rule of Thumb.

Before dealing with that part of my subject, however, I wish to submit that the bad old "rule-of-thumb" days of gelatine dry-plate photography do not expose a very broad target for the arrows of our reproaches. Point for point, and excluding from consideration the well-directed, but unconvincing, productions of the new diffusion-of-focus school, a comparison of amateur and professional photographic work of twelve years ago with that of to-day reveals little, if anything, in favour of the latter. The portraiture of professional photographers is possibly, on the whole, more instinct than formerly with artistic feeling and treatment; but that is not a matter upon which I wish now to descant. It is from a technical standpoint alone that I desire to make the comparison. My own observations lead me to think that, technically speaking, in qualities of negatives and prints, the professional work of to-day is practically what it was a dozen years ago, taking it at both its best and at its worst. The negatives of the former period were, perhaps, not so pretty and clean to look at as those produced nowadays; but will anybody undertake to say that the resulting prints exhibit any traces of inferiority to those of the present time—that the negatives were not so well exposed, or that the prints were inferior in point of careful printing, uniformity, and depth of tone? The same question stands for all other kinds of professional work—always remembering that I wish it to have a technical bearing and no other. It is, of course, not so easy to make a comparison of amateur work, because in the times I am referring to, exhibitions were few and far between; but recalling the pictures shown at Pall Mall and elsewhere at that period, and contrasting them with those of to-day — a mental process in which, no doubt, most of you can accompany me—I fail to perceive that any distinction is to be made. Technically speaking, the work shown then was quite the equal of that shown now, and probably the average of quality was higher.

I have roughly traced the conditions under which photographers—amateur and professional, new and old — formerly had to work. Recollect also that failures were more frequent then than now. Dry-plate making was in its tentative stage, and, consequently, to the difficulties of exposure and development a large number of troubles incidental to the preparation of the film—such as are not often experienced nowadays—had to be habitually encountered. Those were the times of constant frilling, of red and green fog, and of numerous mechanical imperfections in the films; and the percentage of failures was, consequently, high. Yet, notwithstanding these obstacles and drawbacks; notwithstanding unscientific rule-of-thumb methods of exposure and development; notwithstanding a condition of knowledge of applied photography such as many to-day might be inclined, with their superior advantages, to stigmatise as ignorance, we have not, I submit, made any technical advances on the productions of that time. Tastes and fashions have changed in respect of new developers, printing surfaces, and so forth; but a change does not necessarily lead to an improvement in intrinsic quality.

A Plea for Technical Excellence.

Do not, however, suppose that I am not alive to the economical advantages of the improved developers with which we are working; of film photography, of the value of orthochromatic plates for certain classes of work, and of the remarkable cleverness displayed in countless shutters, hand cameras, and so forth. Each of these has its uses according to individual idiosyncrasies, but, if I am correct in my suggestion that in technique photography stands to-day where it stood at the commencement of the last decade, their introduction was not called for by necessity, and their existence is not essential, and has hardly been justified by results. I am unable to understand that they have improved the technique of photography. Technically good photographs, I venture to think, are not so prevalent that we can afford to regard them with the contempt bred by familiarity. At a moment when the art aspects and attributes of photography occupy so much attention, perhaps a plea for technical excellence may not be misplaced. While I have, I hope, as keen an appreciation as any one not an artist of what is artistic in photography, I am equally ready, and I trust capable, of appreciating what is technically good in any photograph, whether it makes pretension to being a work of art or not. Definition, however finely rendered, appeals to my sense of the fitness of things in the contemplation of photographs of architectural subjects, and I am unregenerate enough to prefer it to fuzziness in landscape work, with or without figures. Definition, or sharpness to a refined degree, is in practice not so easily or invariably obtained; a photograph is not so frequently taken from the correct or the most favourable point of view; distortion and other optical imperfections are not so often absent as the critical might desire; the negative is not always so carefully exposed and developed as to secure all the detail and the gradations of the subject; the printing process chosen does not so often do credit to the discrimination or the selective faculties of the photographer; and the resulting print does not so often embody the essentials of what a good print should be, that we can afford to treat excellence of technique with indifference when we meet with it. A perfect photograph of even the most commonplace object is, I consider, a tribute to the skill of the photographer, and from a technical point of view is just as calculated to evoke the admiration and the approval of photo-technologists as an art-photograph is that of an art-photographer. A line drawing to scale of a great public building by an architectural draughtsman has certain elements and qualities in it which appeal to the cultivated perceptions of an architect. Your artist may sneer at its "mappiness," but he dare not and cannot impugn its proportional accuracy and its fidelity. On the other hand, when the artist idealises the same building in his painting, how easy it is for the architect to discover faults of perspective, proportion, and drawing! At the Royal Academy there is (or was) a room devoted to architectural drawings, and, I believe, it is on record that some years ago some such disparity as that which I am now hinting at was pointed out and commented upon.

The Focussing Screen the best Actinograph.

Heretical though it may sound, I do not think that the cause of photographic technique is in the least likely to be advanced by the present disposition, especially among amateur photographers, to base the making of the photograph as much as possible upon rule and system. The rule of thumb and pinch of pyro days of photography are, perhaps, over—thanks, not I believe, to formulæ-mongers and mechanico-arithmeticians, but to the fruits of experience and experiment. I consider it an unfortunate thing in several respects that there are so many inducements to modern amateur photographers to attempt the acquirement of a sound photographic judgment by other methods than that of simple experience. Let me cite, in point, those so-called aids to exposure: actinographs, actinometers, and exposure-meters, as calculated rather to prevent the cultivation of individual judgment than to foster it. You must remember that professional portraitists and landscape-workers, and the old-style amateurs, of whom I have already spoken, relied upon experience alone to guide them in their exposures. My own belief is that a man who takes up photography will surmount the difficulties of exposure by the aid of his own brains, or not at all. If he has not brains enough for that, then he is equally incapacitated for mastering the philosophy of exposure-calculators. I am about to examine some of the principles upon which actinometrical or actinographical systems are based, and possibly to draw some conclusions not entirely favourable to them; but, before doing so, there is one exposure-meter which I must exempt from objection. Indeed, I recommend it to each and every one of you. It is, I think, the cheapest and most efficient on the market, does not get out of order, if destroyed may be easily replaced, requires no arithmetical calculations to use, and and may be had of all dealers. It has been testimonialised by the most successful photographers throughout the world, and, when once its application is mastered, it seldom leads you astray. With it all the best photographs have been taken, and thus, in regard to medals, it, as our friends at Ilford would say, has secured more than all the rest. It is an exposure-meter which enables the photographer with brains enough to use it to get twelve good negatives from a dozen plates. No photographer should be without it, and no photographer is. Need I say, gentlemen, that I allude to the focussing screen of the camera? It is by the study of the image on the screen, it is by comparing the depth of the shadows, the strength of the half-tones, the brilliancy of the high lights, with those of other pictures taken under similar circumstances; it is by studying the visible influence of the lens diaphragms on the brightness of the image; in short, by comparing the exposure about to be given with that previously given under similar or different conditions, as the case may be, that experience was gained in former times. It is theoretically a very unscientific method, of course, but you all know how well it has answered practically. Occasionally it fails; but can you conceive of an infallible actinograph? Besides,

it is good that it should fail at times for what an education in development under and over-exposure provides for the painstaking photographer who is willing, as he should be, to learn from his failures! You may say to me that these last advantages also accrue to the employment of an exposure-meter or an actinograph? Granted; but, in that case, why use an exposure-meter or an actinograph? An instrument or system of this nature, plus an unerring judgment of those factors in exposure compulsorily left to the estimation of the individual, and which is fallible, seems to me not to possess any point of superiority to the unaided fallible judgment alone. I shall endeavour to show that the probabilities of any instrument or system for indicating correct exposure can scarcely be other than incorrect, to the contrary of which there are practical objections which science is, I believe, powerless to overcome.

No Exposure Factors "Constant."

Mr. Howard Farmer recently pointed out that several important factors are not taken account of in certain systems of calculating exposures; but, even if the omitted factors—such, for example, as colour and distance of object—were included, I still submit that theoretical or practical accuracy could not possibly be assured. To the inexperienced or the beginner in photography, for whom, bear in mind, all these aids or guides to exposure are intended, the difficulty of estimating, or, rather, of judging the actinic value of the light on any day or at any hour is no inconsiderable one, especially if you reflect that even a photographer of ripe and lengthy experience is occasionally mistaken in his judgment. I have seen it stated that of the three principal factors involved, viz., the light, the speed of the plate, and the aperture of the lens, the two latter are constant. But the ascertained comparative or particular speed of a plate so soon as it leaves the manufacturer's drying-room does not appear to be above suspicion of change. Quite recently, Dr. Vogel, of Berlin, gave instances where commercial plates materially increased in sensitiveness after a month or two's keeping, and the same phenomenon has been claimed to have been observed by several other workers during the last few years. On the other hand, some photographers have concluded from the results of experience that sensitiveness diminishes by keeping. If either of these two theories is correct, the speed of a plate, no matter how it is ascertained, cannot be reasonably accepted as a constant factor in exposure calculations. Again, the argument, in reference to the aperture of the lens, that all lenses are of equal rapidity with a given stop, assumes two conditions which are far from being always realised, namely, that the diameters of the stop openings are accurately expressed in relation to focus, and that all lenses are on an equality as to the amount of light they pass. Optical glass, however, is, I believe, of somewhat varying quality as regards colouration, experiment having proved that even in modern lenses as much as twenty-five per cent. of the light is occasionally obstructed by the colouration of the glass as compared with the glass employed in other objectives. One can easily understand that time superinduces changes in the glass of lenses as well as in the material with which they are cemented so as materially to slow them. Can it, then, be fairly claimed that all or either of the three factors I have referred to are to be accepted as constants in basing calculations upon them? If so, in what manner will you dispense with individual judgment if you admit, as you must, the no less important factors of colour and distance of objects to your calculations? I put it, that constancy of any of the factors in exposure calculations is far from being the certainty we are asked to believe.

"Formulæ."

That exposures calculated according to the systems we are now discussing are sometimes correct, I do not deny; it would be strange were it not so. But an exception does not negative a principle, and it is a principle I am urging, namely, that of buying photographic wisdom by photographic experience. The world's photography has so far been accomplished by the aid of the actinometrical readings of the focussing screen; why, then, should the beginner or student expect to extract from mere empiricism the knowledge which has been shown to result from the reliable, although "unscientific," method of trial and error? The plethora of new developers, the legion of hand cameras and rapid shutters, the numerous exposure systems seem to me to be the articulate expression of a wish to compress photograph-taking into a rule-of-three sum, and so to enable one to run without the necessity of having to learn to walk. Do not understand me as advocating rule of thumb; I am merely advocating the exercise of the individual intelligence as opposed to falsely inspired formulæ. The word "formulæ" here induces me to recommend to you a source of instruction as to the wide range in the differences of opinion which prevail among dry-plate makers and dry-plate users in respect of the proportional constitution of developing formulæ. Make a collection of such formulæ from representative sources, and convert them either into parts per thousand or grains and minims per ounce, and you will assuredly have a most bewildering statement of proportions of accelerator to reducer, and of restrainer to both, together with a lengthy list of ingredients which appear in some formulæ and not in others, and the exact functions of which many people would find it difficult to define. In the normal developer for A's plates, for example, you may see one and a half grains of pyro, eight of sulphite, and ten of sodium carbonate to the ounce; in B's developer the quantities doubled; in C's one constituent quadrupled and another halved, while in D's the inter-proportions suggest nothing so much as the constituents having been selected purely by hap-hazard. The curious part of the matter is, that in all probability A's developer will develope C's plate perfectly, and D's B's, and so on; in short, each or any one of the many developers you analyse, although specifically recommended for one brand of plates, will develop any other brand equally well. So much the better for the users of gelatine plates, you will say, and I endorse the sentiment, but do not overlook the obvious point, and that is, that after all the years during which "scientific development" has been preached, practically the old rule of thumb still survives, and that, on the whole, photography is little the worse for it.

"Photography Made Easy."

The commercially created and fostered tendency among amateur workers to substitute for the mellow judgment of experience and unwearying practice the ephemeral wisdom of the many aids to easy photography which shrewd men of business are always anxious to supply on demand, tends, in my humble opinion, to undermine those valuable characteristics of practice, patience, application, self-reliance, and perseverance which have hitherto been recognised as essential to the making of the successful photographer, amateur or professional. Frankly speaking, I look upon it as one of the causes to which we may refer the admittedly low average of quality of modern amateur work. The best amateur work of to-day is undoubtedly as good as, and possibly better, than the work of ten or twelve years ago; but the average strikes me as lower, an opinion which I base on a comparison of the work shown on the walls of exhibitions during that time. Probably the seductive simplicity of the hand camera and the fascinating facility of shutter work have also operated in the same direction.

In conclusion, I renew the plea I have already entered for technical excellence of photographic work, for technical skill in producing it, for technical instinct in appraising it. But that excellence, that skill, and that instinct can only be reached by assiduous cultivation. Believe me, while there are many persons to whom a photograph is only admissible when it appeals to their æsthetic emotions, there are probably a far larger number who, while ready to welcome the artistic effects produced by "diffusion of focus" and low-keyed tones on rough surfaces, have a higher appreciation of the technical qualities previously referred to. Whether or not the cause of technical photographic excellence and progress is likely to be promoted by the attempts now being made to convert photography into an involved arithmetical exercise, and, in fine, what the tendencies of that movement are, is a point for discussion that I have endeavoured to lay bare to you in the course of a series of intangible generalisations and impressionistic reflections which, I hope, while blunting the edges of your critical dissecting knives, have not wholly undeserved the attention you have been so good as to bestow upon them.

Thomas Bedding.

THE NEW CONCENTRIC LENS.

(Photographic Society of Great Britain.)

The following is the paper by Messrs. Ross & Co., read at the meeting of the above Society on May 24:—

The construction of a lens to give a "positive" focus, or that caused by rays of convergence, has hitherto been obtained by the radius of convexity of one refracting surface being shorter than the concave one. As an illustration of this, take a simple lens of the form shown in the diagram (Fig. 1, *a*, or as achromatised in *b*). If the meniscus form of this were to be altered by making the concave surface deeper, as in *c*, the lens would have no convergent focus at all, the rays would become divergent, and the result would be negative. Supposing this lens to be a compound, made up of crown and flint glass, the latter having the greater refractive power, it will still be observed that the sum of all the positive curves is deeper than the sum of the negative radii. This form of construction is reversed in the Concentric, in which lens the convex surface has a longer radius than the concave, as in *c* above, the diagram of which

would at first sight lead one to expect a negative focus without any image; but this is not the case, for, by the selection of a suitable crown glass for the positive element of higher refraction than the flint of the negative element, the rays are caused to converge, and, by the special effect of refraction on the oblique pencils, the lens, although of this peculiar form, gives a real image, free from distortion, on an abso-

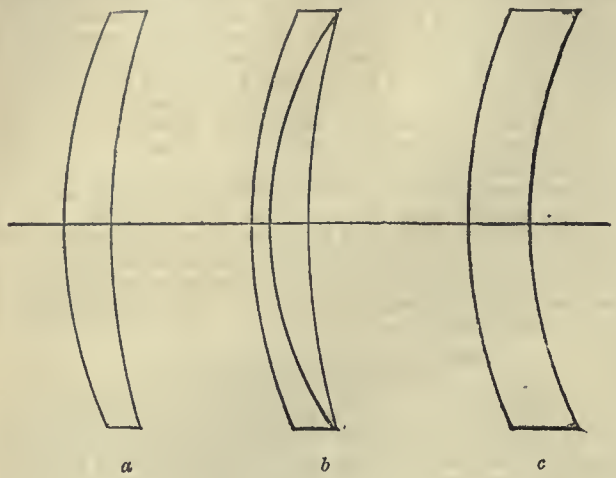

Fig. 1.

lutely flat field, extending over a circle of about 75°, the margin being as sharply defined as the centre; and, moreover, the whole is practically as equally illuminated as the theoretical limits will permit.

Every simple lens is represented by a system of prisms, whose angles are formed by the tangents of the radii. If two prisms or lenses are cemented together to form an achromatic prism or lens, the angles of the two components are in a certain relative proportion, determined by the ratio of refraction and dispersion of the glass employed. When rays pass through such a lens, achromatic both at centre and margin, these angles may then be greater, yet the relative ratio of both must be the same as those at the centre, for, if they differ in ratio, the marginal pencils will not be achromatic, and will be deviated in undue proportion, and, besides colour, will cause optical distortion. Taking an ordinary compound meniscus lens, whose curves are represented in the diagram (Fig. 2), we find that the tangents of the three curves are parallel at the centre, so that

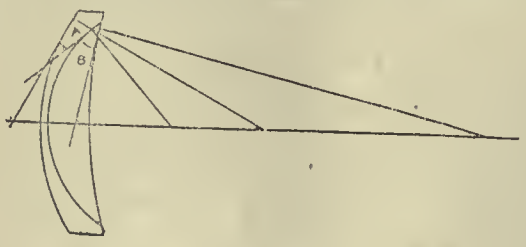

Fig. 2.

there is no distortion or deviation of the direct incident pencils; but, as we leave the centre, we find that the tangents of the first and second curves approach one another, forming a wedge or prism, and the tangents of the second and third curves form a similar prism of smaller angle and in the reverse direction. This implies a greater power of the crown lens at the margin; and, as this has positive aberration, the image produced by the margin of the achromat must be smaller than the central image, and hence barrel-shaped distortion and coloured fringes are produced. In the other diagrams (Fig. 3) representing the "Concentric" lens, it is evident, on consideration, that, on account of concentricity, the two tangents, which, with the central plane, form the prisms, are always parallel, and the angles formed in constant ratio. Such an achromat will therefore produce neither general distortion nor distortion of the coloured images.

The field of the Concentric lens is practically illuminated equally all over. In all lenses the diaphragm reduces the amount of light in proportion to the deviation of the oblique cone of rays from the central cone (Fig. 4). This diminution of light towards the margin of the field is small, however, when compared to that due to astigmatism and longitudinal spherical aberration in all ordinary lenses. The elliptical appearance of the diaphragm, caused by the oblique direction in which it is viewed, is exaggerated by the distortion in ordinary lenses, which have the property of diminishing objects in the horizontal diameter, whereas in the "concentric" lens the diaphragm retains its circular shape until the light has nearly vanished. This is the effect of the opposite refraction, due to the negative meniscus form having a positive focus, and which tends to open out—so to speak—the diaphragm to its normal circular form. An ordinary lens, bringing its central rays to a sharp focus, may be so constructed as to do so

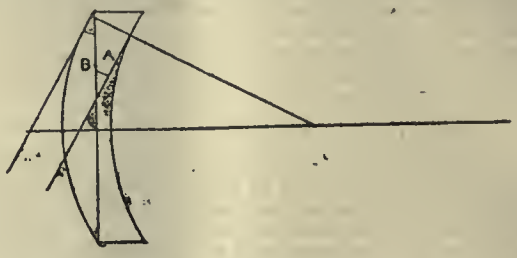

Fig. 3.

marginally also, but only on a curved field, a flat field being alone obtainable with such a lens by the undue lengthening of the marginal pencils, resulting in astigmatism at the expense of definition. The rays do not actually meet in one point, so that the major portions are lost, or worse, as they only assist to obliterate the sharpness of the actual working rays. In the "Concentric," however, the whole pencil of rays go to form the image equally at the margin as at the centre.

Theoretically, a lens has no depth of focus; or, to speak more correctly, no depth of definition, for, optically, focus is a point. At the focal point the sharpest definition is obtained; but on each side there is a certain amount until the aberration becomes so great as to be perceptible. Ordinary lenses, which come to focus sharp only in the centre of the field, with vanishing distinctness towards the margin, are said to possess a certain depth of definition; but this is alone true for the centre, the remainder of the field being only a compromise for definition at all. In the "Concentric," however, we start with sharp and equal definition all over the field, due to its novel system of construction, and thus the definition of all objects situated equidistant from the principal focussed object is equalised. Also, as there is no distortion or deviation of any point of the cone of rays, they may be said to cling closer together for a longer distance on each side of the point of true focus. The "Concentric," therefore, more nearly yields the theoretical amount of depth of definition (regulated more or less by aperture) than any other lens, and consequently may be said to possess greater depth of focus or definition over the entire field.

In practice it is found that the "Concentric" lens is considerably more rapid than other lenses of equal aperture and focus. By referring back to the diagram (Fig. 2) shown to illustrate the loss of rays from spherical aberration and distortion, it is apparent that the

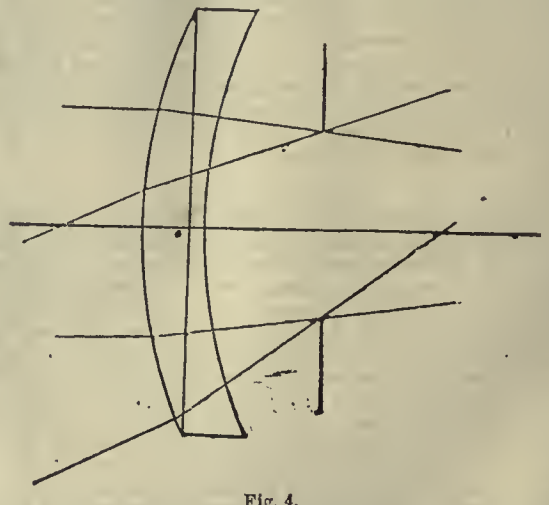

Fig. 4.

whole cone being brought to a focus in the "Concentric" without distortion the "Concentric" consequently works quicker than lenses in which a portion of the rays only is used, and where the non-focussing merely interfere by throwing useless light into the shadows.

Having now drawn attention to some of the chief differences between the "Concentric" and other lenses, it will be desirable, before

proceeding, to examine and compare these lenses optically, to explain the principle upon which the testing apparatus is constructed. We use a stand to carry a photographic lens in direct line between a

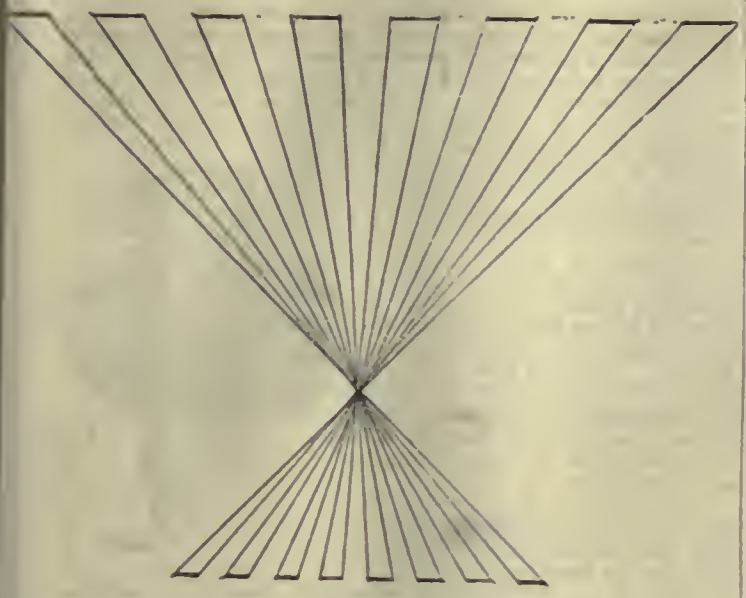

Fig. 5.

stationary lamp and a concentric aplanatic magnifier; the adjustments attached are to alter the distances between the positions for convenience of focussing. Having by this means examined the central

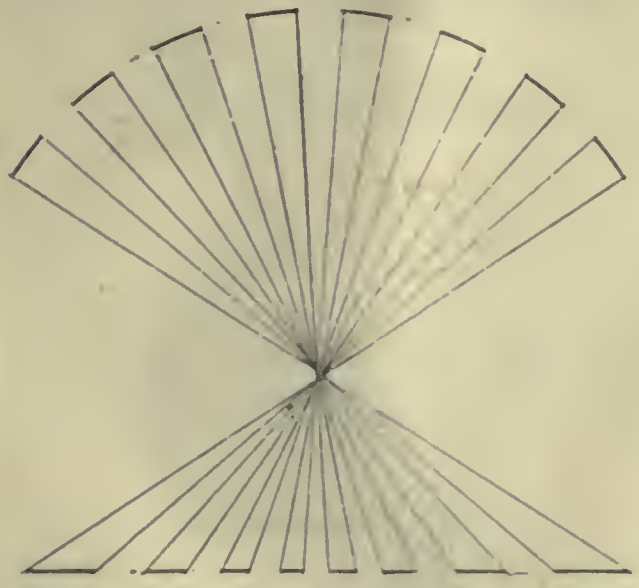

Fig. 6.

pencil, the magnifier at the back is moved aside in a line towards the margin of the field, and a movable lamp placed at a distance is traversed on a plane, parallel and at the same level as that in which the magnifier is moved, and which corresponds to the surface of the ground glass of a camera; the magnifier is moved sideways until the lamp and attached dial are visible, the angle subtended then being equal to that of the opposite side. This represents the view angle, or, as the case may be, the diagonal of covering at that particular angle. The two diagrams herewith (Figs. 5 and 6) represent the principle upon which this method of testing is based, and it will be found that all that has been stated in connexion with the "Concentric" lens is optically correct, both when taken by itself and in comparison with other lenses. It should be mentioned that, the magnifier being of the form of a sphere with concentric surfaces, the focal distance from the centre is the same at all angles of obliquity, so that it requires no axial adjustment to meet the line of an oblique ray.

DISRUPTION OF THE SILVER HALOID MOLECULE BY MECHANICAL FORCE.

[Philosophical Magazine.]

In a paper published about a year ago on the subject of Allotropic Silver, there was included an investigation into the action of the different forms of energy upon silver chloride and bromide.* It was there shown that these substances possessed an equilibrium so singularly balanced as to be affected by the slightest action of any form of energy. Such action produced a change which, though it might be wholly invisible, yet caused the breaking up of the haloid when subsequently placed in contact with a reducing agent. The forms of energy with which this effect was observed are—

1st. Heat.

2nd. Light.

3rd. Mechanical force.

4th. Electricity (high tension spark).

5th. Chemism.

It follows, therefore, that it is not light only that is capable of producing an invisible image, *but that this power belongs alike to all forms of energy*. So that a slight impulse from any one of the forces just mentioned brings about a change in the equilibrium of such a nature that the molecule is more easily broken up by a reducing agent.

As respects four out of these five forms of energy, it was further shown that when made to act more strongly, they were able of themselves to disrupt the molecule without external aid. One form alone of energy, mechanical force, made an apparent exception to this general rule. The other four, when applied to a moderate extent, produced a latent image; applied more strongly, they broke up the molecule.

The object of the present paper is to prove that this exception does not exist, and that as all forms of energy have been shown in the previous papers of this series to be capable of impressing an invisible image, so also with stronger manifestations, *any form of energy is capable of disrupting the molecule*.

I was able to show many years ago that mechanical force could produce a latent image. Lines drawn with a glass rod on a sensitive surface could be rendered visible by development in the same way as impressions of light. An embossed card pressed on a sensitive film left an invisible image, which could be brought out by a reducing agent. The raised portions of the embossed work exerted a stronger pressure on the sensitive film than the rest of the card, and these portions darkened when acted upon by a reducing agent. In the same way, the lines traced with a glass rod blackened under a developer. In each case, it was the portions which had been subjected to pressure which yielded first to the reducer. It was therefore clear that in the molecules which had received this slight pressure the affinities of the atoms had been loosened.

To bring these phenomena fully into line with the others, it is now necessary to prove that an increased pressure can take the place of a reducing agent, and disrupt the molecule. And this is actually the case.

It was found that the breaking up could be produced in two ways—by simple pressure and by shearing stress. Silver chloride and bromide formed and washed in absence of active light were subjected to these agencies.

1. Simple Pressure.

In the first trial made with silver chloride it was enclosed in asbestos paper, which had been first ignited with a blast lamp to remove all traces of organic matter present. This method was tried in order that the chloride should be in contact with perfectly inactive material only, but it was not found to answer. The great pressure

* *Philosophical Magazine*, April 1891, p. 320.

employed forced the dry chloride into the pores of the paper, cementing it together, so that the opposite sides could not be separated. Platinum foil was then substituted with satisfactory results. With a pressure of about one hundred thousand pounds to the square inch, maintained for twenty-four hours, the chloride was completely blackened, except at the edges, where, owing to greater thinness, the pressure was less. Very bright foil was used in order to detect the slightest discolouration that might occur, but none resulted: it was impossible to distinguish the portions which had been in contact with the darkened chloride from those that had not. The chloride did not assume the usual chocolate colour, but changed to a deep greenish black.

Silver bromide gave exactly the same results. It should be mentioned that the silver chloride and bromide were each precipitated with an excess of the corresponding acid.

As silver iodide precipitated with excess of potassium iodide is not darkened by light it seemed improbable that it should be by pressure. The experiment was, however, tried, and it was found that the iodide darkened fully to the same extent as the others. This result surprised me so much that the experiment was repeated with every possible precaution. The result left no doubt that silver iodide, as well as the chloride and bromide, is blackened by great pressure. All three silver haloids take on the same colouration—an intense greenish black. It was found best to use the material air-dried. If at all moist, the platinum foil bursts under the pressure and the experiment is invalidated. The air-dried salt retains a sufficient quantity of moisture.

2. Shearing Stress.

As a means of applying this form of force, the silver chloride, precipitated with excess of hydrochloric acid and well washed, was put into a porcelain mortar and well triturated. The improbability that the small quantity of force that can be applied in this way would break up a stable molecule like that of silver chloride seemed so great, that at first a substance tending to aid the reaction was added. Tannin was selected, and when forcibly ground up with silver chloride the latter was soon darkened. Next a substance capable of taking up acid, but having no reducing action, was tried. Sodium carbonate was used. This also caused the chloride to darken. Finally, it was determined to ascertain if the molecule of silver chloride could not be disrupted by stress alone. The chloride was placed in a chemically clean porcelain mortar and well triturated. For some time no effect was visible. After about ten minutes' action dark streaks began to appear, and after five minutes' more work a considerable portion of the chloride was darkened. The end of the pestle was covered with a shining purple varnish. It had not become perceptibly warmer to the touch. On the violet-purple substance nitric acid had no action, but aqua regia slowly whitened it. It was therefore what I have proposed to call silver photochloride, that is, a molecular combination of chloride and hemichloride. This experiment was carefully repeated with the same result. Silver bromide similarly treated gave a similar result. It was noticed that both chloride and bromide, in darkening, took on the familiar colour between chocolate and purple, so generally seen in the darkening of these silver salts, and differing strikingly from the greenish-black colour assumed by all three silver haloids under simple pressure.

The fact that the platinum foil remained absolutely unattacked when the silver haloid was reduced by simple pressure in actual contact with it is interesting, and would seem to show that in the reduction of the silver haloid the halogen is not at any time set free; but that water, if present, is decomposed at the same moment, with formation of halogen acid.

The observations recorded in this paper prove the existence of a perfect uniformity in the action of all kinds of energy on the silver haloids. The balance of the molecule is at once affected by the action of any form of energy. A slight application produces an effect which, though invisible to the eye, is instantly made evident by the application of a reducing agent. The bonds which unite the atoms have evidently been in some way loosened, so that these molecules break up more easily than those to which energy has not been applied. Consequently, if the substance is submitted to the action of light, heat, or electricity, or if lines are drawn by a glass rod (shearing stress), or with sulphuric acid (chemism), a reducing agent blackens the parts so treated before it affects the parts not so treated. This justifies the statement made earlier in this paper, that the phenomena of the latent image and of its development are not exclusively, or even especially, connected with light, as hitherto supposed, but belong to all other forms of energy as well.

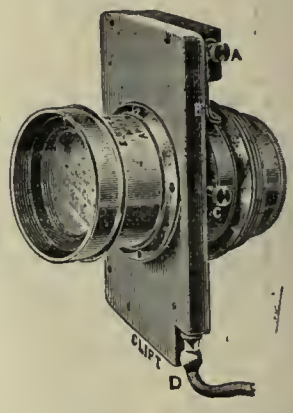
M. Carey Lea.

(To be concluded.)

Our Editorial Table.

Le Constant.

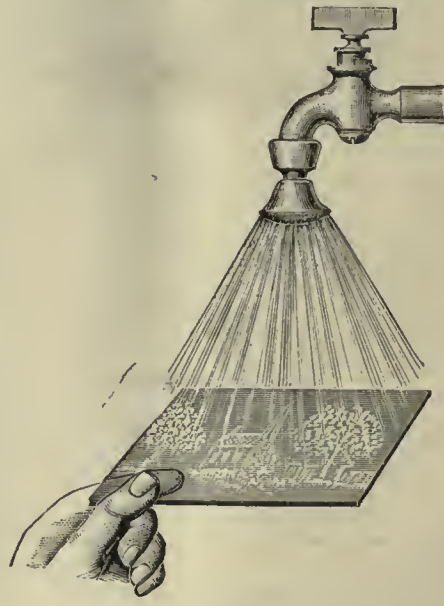
This is the name given to a shutter, or, to be more explicit, a series of shutters, of the "always ready," or automatic class, for which Mr. J. R. Gotz, 19, Buckingham-street, Strand, W.C., is agent. One of these, now before us, is arranged for the stereoscopic camera, and fits on the hoods of the lenses, being firmly fixed thereto by thumbscrews. When set for instantaneous exposures, pressure on the pneumatic ball suffices to discharge it, and, as no setting is required, this may be made to go on interminably. By setting a lever, the action is brought under the direct control of the ball, upon pressure of which the shutter flies open, and remains so until the pressure is relaxed. By pushing in a button at one end, the shutter remains open permanently to permit of focussing. This is a most delightful shutter. We exposed several dozen stereoscopic plates by its agency during the late Convention in Scotland, and the certainty of its action charmed every one who saw it.



Another of the same class of shutters, or another application of the principle, is that shown in the cut. Whereas the former one is fitted on the front of the lens, this goes between the lenses of the combination, which is undoubtedly the best position. The parts indicated by letters show respectively the manipulatory points at which time and instantaneous exposure, speed regulator, operating an iris, or inserting a Waterhouse diaphragm, and attaching the pneumatic tube are effected. The workmanship is admirable.

Tylar's Tap-sprinklers.

Mr. William Tylar has sent us specimens of two styles of tap-sprinklers which he has just brought out. While they slightly differ



as regards form, both are equally effective in action. They fit easily on ordinary taps, and their nature and use will be ascertained from the diagram.

Photographic Reproduction Processes.

By P. C. Duchochois.

London: Hampton Judd, & Co., 13, Carsitor-street.

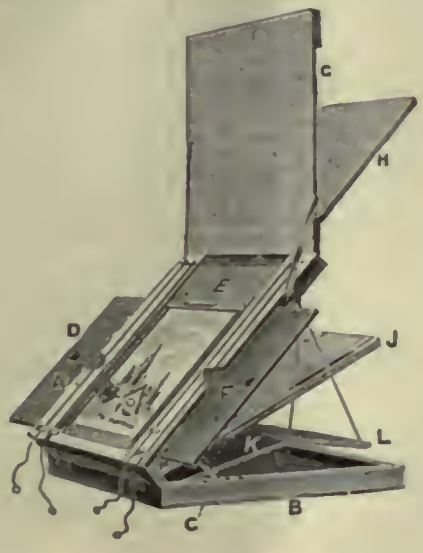
In this work the author treats very fully and clearly of most printing processes, ancient and modern, other than those in which the salts of silver form the sensitive layer. Iron and uranium

printing methods find a prominent place, and many other little known processes are dealt with, which should make the book useful for reference to those who desire a collected account of the results of the experiments of Hunt, Herschell, Burnett, and many others who in former times devoted a large share of their labours to the invention of printing processes, some of which, although lost sight of at the present moment, are probably destined to be resuscitated. The book is well bound and printed.

The Photo-Chromoscope.

This ingenious invention has been placed on the market by Messrs. G. Houghton & Son, of High Holborn. It was shown at the Edinburgh Convention. By its aid transparent photographs can be transformed into realistic pictures, perfect in detail, in perspective, in light and shade, and in general tints, and susceptible of a variety of natural and pleasing changes of effects.

The apparatus should be arranged in the first place as shown (opened) in the cut, the back exposed to a fairly strong light—a window during the day, or a lamp adjustable to any required position at night; the photograph to be exhibited being placed in the glazed frame A, and (if necessary to keep it flat) covered by a pane of glass, and the sliding panels, D, E, F, being adjusted so as to exclude the light from all that portion of the frame not occupied by the picture.



The light being thus excluded from the surroundings of the semi-transparent photograph at the front, and thrown upon it strongly at the back, many of the details which are ordinarily indistinct are clearly brought out.

By various adjustments of the parts of the apparatus it is available for the exhibition of landscapes, portraits, and statuary, a great variety of effects being obtained by the depression or elevation of the shade H, the sky frame J, or the reflectors K, L, as well as coloured slips placed at L alone. Messrs. Houghton supply a full descriptive pamphlet.

PATENTS COMPLETED.

An Improved Rocking Apparatus for Photographic and other Purposes.

No. 14,286. George Francis Pittar, 48, Hungerford-road, N., Middlesex, and Ernest Thompson, 10, Marlborough-road, Lee, Kent.—*June* 25, 1892.

This invention has for its object the construction of a series of troughs, sinks, and connexions, to be actuated by the flow of water or other liquid, for rocking or washing photographic plates or prints. Also for combining the processes of developing or washing with rocking. Also for obtaining a rocking motion for any other purpose.

It consists of the following parts:—

1st. A double-ended trough, with ends inclined outwards, having a cross partition in the centre. This trough is arranged on trunnions, having a crank attached to one trunnion for the purpose of actuating the rocking tray.

2nd. A rocking tray, consisting of a flat sheet of metal, with projections to support object to be rocked or washed. This tray is balanced on pivots, and connected to the trunnion crank by a rod.

3rd. An inlet pipe, arranged over the central partition of rocking trough in such a manner that the water or other liquid can flow on to one side of partition. This fills one side of trough, and causes it to drop and empty into the sink underneath, at the same time raising the other end of trough. From this sink the liquid may be allowed, if necessary, to run over the object to be rocked or washed, which is placed on the rocking tray. The pipe now fills the other end of trough, and causes it to drop and empty, thus producing a rocking motion, and ensuring a continual movement of the object operated on, and also bringing fresh liquid in contact with it. The liquid, by actuating the rocker thus, may serve two purposes.

The rocking tray is arranged in a suitable sink with outlet.

The greater part of this apparatus is preferably made of tinplate, and will be exceedingly cheap to manufacture.

Having now particularly described and ascertained the nature of our said invention and in what manner the same is to be performed, we declare that what we claim is:—1. The combination with a platform mounted upon pivots or trunnions of a double-ended trough also mounted upon pivots or trunnions and connected with the said pivoted platform in such a manner that, when the said double-ended trough is caused to oscillate by alternately filling the ends with water and emptying the same, the said platform will also be caused to oscillate, substantially in the manner described. 2. In a rocking apparatus provided with a double-ended oscillating trough as described in the preceding claiming clause, providing the said double-ended trough with a central partition for alternately directing the water into the opposite ends thereof, substantially as described. 3. The manufacture and use of the improved rocking apparatus hereinbefore described and illustrated in the accompanying drawings, and operated as and for the purposes set forth.

Improvements in Photographic Apparatus.

No. 14,336. Charles Walker Clarke, 32 Market-place, Devizes, Wilts.—*June* 25, 1892.

This my invention relates to certain improvements in or relating to photographic apparatus, and consists of a shade for cutting off or screening a part of the light from certain parts of a view during exposure in the camera, such as the sky in a landscape, or windows in the case of an interior.

This screen may be of any suitable material, but I prefer to use either celluloid, or glass stained or tinted in places, but graduated off to an absolute transparency.

For taking a landscape photograph, I should generally use a screen in such a position that it would cover the sky as seen through the ground glass, and should set it in such a position that the transparent edge of the screen just clears the horizon in the view (this I should regulate by a graduated scale attached to the screen, and a corresponding scale attached to the ground glass).

I find that, by this means, I am enabled to obtain a negative of much more uniform density, and to obtain pictures of clouds which, without the use of the screen, would not appear at all.

The screen may be used in any convenient position, either in front, between or behind the lenses, but I find it convenient to make the screens to slide in a slot in the same manner as a Waterhouse diaphragm; but sometimes I use either a circular screen to revolve, a square screen to let down from the top, or to be pushed through the side, inside the camera, with suitable arrangements for manipulating the same from the outside. This screen is formed either in different shapes, or with tints of different depths, or with different patterns (preferably round its circumference), and is arranged in such a manner that more or less of either tint, or pattern, or screen, may be brought into the view as required.

To screen a window in the case of an interior exposure, I should select a screen having one or more suitably stained and graduated spots, which I should arrange in such a position that it would shield or screen off the bright rays as seen through the ground glass of the camera.

It will be understood that the object of this invention is to reduce the greater illumination proceeding from certain parts of the subject, such as the sky or a window, leaving the darker portions unscreened.

The device may be either combined with the camera, the lens, or the shutter, or, if desired, it may be a separate or independent attachment.

It may sometimes be desirable to use two or more screens for different parts of a subject.

If desired, the screen may consist of a cloud scene, made by photographic or by any other means, and used preferably inside the camera, so that by this arrangement clouds may be included in a negative, even when the sky is clear, or any other device by the same means may be formed on the screen for insertion in the negative.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—1. The combination with an apparatus for exposing a photographic plate or film of a semi-transparent or tinted screen so arranged that it only covers a part of the view, and is brought into position after the view or a portion of the view has had a short but complete exposure substantially as described. 2. The combination with an apparatus for exposing a photographic plate or film of a semi-transparent or tinted screen which only covers a part of the view, so arranged that it can be partially or wholly removed, giving a short but complete exposure to a part or the whole of the screened portion of the view before the shutter is closed substantially as described. 3. The combination with an apparatus for exposing a photographic plate or film of a semi-transparent or tinted screen which only covers a part of the view, so arranged

and operated that a short but complete exposure is given to a part or the whole of the screened portion of the view, both before and after the screen is brought into operation substantially as described. 4. The combination with an apparatus for exposing a photographic plate or film of a semi-transparent or tinted screen so arranged that it only covers a part of the view, and is graduated off to an absolute transparency at one or more of its edges, and so arranged that it reduces the amount of light which reaches a portion of the photographic plate or film substantially as described. 5. The combination with a photographic lens of a semi-transparent or tinted screen which only covers a part of the view, and which is graduated off to an absolute transparency at one or more of its edges, and so constructed that it may be inserted and used in the diaphragm slot together with, or instead of the stop, substantially as described. 6. The combination with a photographic lens of a semi-transparent or tinted screen which only covers a part of the view, the form of which is capable of being cut or altered to suit the subject intended to be taken on the photographic plate or film substantially as described. 7. The combination with an apparatus for exposing a photographic plate or film of a frame, arranged to hold a semi-transparent or tinted screen, and which slides in a slot, and is connected with the top of the rod by which the flap is worked, substantially as and for the purpose described and illustrated in the accompanying drawings. 8. The combination of a semi-transparent or tinted screen, with a frame, arranged to be brought into operation by the movement of a shutter, substantially as described and illustrated in the accompanying drawings. 9. The combination with an apparatus for exposing a photographic plate or film of a semi-transparent or tinted screen which only covers a part of the view, and which is graduated off to an absolute transparency at one or more of its edges, and has one or more of its edges straight or curved, and is supported in front or behind the lens in such a manner that it reduces the light which reaches certain portions of the photographic plate or film, substantially as described. 10. The combination with an apparatus for exposing a photographic plate or film of two or more semi-transparent or tinted screens which will only cover part of the view, and which are graduated off to an absolute transparency at one or more of their edges, and have one or more of their edges formed either straight or curved, and which are so arranged that they obstruct or reduce the light which reaches certain portions of the sensitive plate or film. 11. The combination of a photographic camera with a semi-transparent or tinted screen which only covers a part of the view, and which is graduated off to an absolute transparency at one or more of its edges (which, if desired, may be curved), and which is arranged behind the lens and inside the camera in such a manner that it screens or reduces the light which reaches certain portions of the photographic plate or film, and that it may be adjusted from the outside, and operated either by the action of the shutter or independently, substantially as described. 12. The combination with an apparatus for exposing a photographic plate or film of a transparent screen having more or less, but not the whole, of its surface stained or tinted in such a manner that it obstructs or reduces the light which reaches the sensitive surface from the lighter part or parts of a view, substantially as and for the purpose described. 13. The combination with an apparatus for exposing a photographic plate or film of a transparent screen, which is stained or tinted more at certain parts than others in order to reduce or qualify the light which reaches the sensitive surface, substantially as and for the purpose described.

A New or Improved Focussing Device or Cloth for use in Photography and the Like.

No. 18,702. Ann Van der Werff, 37, Dockwray-square, North Shields, Northumberland.—*June* 25, 1892.

This invention relates to a new or improved focussing cloth or mask for the use of photographers and for like purposes.

In carrying this invention into practical effect, I provide a mask so constructed as to closely fit over the eyes of the operator, and formed with an opening or openings through which he may view the focussing screen. One end of the focussing cloth is secured round, or partially round, the edges of the mask, which may be provided with a handle with which it may be held in position before the operator's eyes.

In a modified arrangement the mask may be held in position by an elastic or other band passing round the operator's head or ears. The said mask may, or may not, be provided with a magnifying lens or lenses, arranged in the openings through which the operator looks, in order that the image on the focussing screen may be closely examined.

In a further modification, I form one end of an ordinary focussing cloth as a mask, or partial mask, to fit over the operator's eyes, and strengthen the said mask by forming it upon a frame of wire or other suitable material.

It will be readily seen that this combined focussing cloth and mask does not obstruct the breathing, and is specially adapted for use in the open air, as the wind cannot blow it up from around the operator's head, as is so frequently the case with the ordinary cloth.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—A new or improved focussing device for use in photography and the like, consisting of a focussing cloth, formed at one end as, or attached to, a mask, or partial mask, to fit over the operator's eyes, substantially as and for the purpose hereinbefore described and set forth and illustrated in the accompanying drawings.

Improvements in Supports for Photographic Cameras.

No. 11,372. George Mason, 180, Sauchiehall-street, Glasgow, Lanarkshire, N. B., and Alexander Lamont Henderson, 277, Lewisham High-road, St. John's, Kent.—*July* 2, 1892.

This invention relates to photographic camera supports of the tripod or jointed-leg class, and has for its object to provide improved adjustable mechanism for fixing the legs rigidly in a required position, so that they will not tend to spread or otherwise move in a manner to alter the position of the camera.

The improved mechanism consists, in the case of a tripod stand, of three steadying bars, with a clamping screw or screw box for fixing them together centrally, with the bars radiating from the centre to a greater or less extent as required in each case. The outer ends of the bars are fitted with parts for easy attachment to the tripod legs. In the case of a common construction of tripod stand, in which each leg is locked upon the pins in the top frame on which the leg is hinged by a strut or turn-down pin which distends the sides of the leg, the ends of the steadying bars may be arranged to engage with the said struts, or the struts may be formed on the ends of the steadying bars. Any other convenient means for connecting the steadying bars to the tripod legs may be used. The steadying bars may be slotted longitudinally, the clamping screw passing through the slots and the bars being pinched between the head of the screw and a nut; or the steadying bars may be unslotted and be passed through slots in a small box, a screw screwed into one end of the box serving to fix them.

When an operator is adjusting his camera the clamping or fixing screw will be loose, and the adjusting bars free to move with the legs, and, on obtaining the adjustment, he will simply have to turn the screw until tight.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

July 26,—Technical Meeting, Mr. Alexander Mackie in the chair.

Modern Developers.

Mr. H. Chapman Jones exhibited a sample of eikonogen, which he had had for three years, and which had not blackened. He observed that eikonogen crystallised out from a sulphite solution would be perfectly white. He had kept an eikonogen solution for a year, and it had worked well. The addition of bromide had been said to be disadvantageous, but he found a small amount gave more detail and a better image. He preferred sodium carbonate to the caustic salt, and gave the following as his formula:—

Eikonogen	25 grains.
Sodium sulphite	50 ,,
Sodium carbonate	50 ,,
Potassium bromide	½ ,,
Water	1 ounce.

For use, he diluted this with an equal volume of water. In reference to the solubility of eikonogen, Mr. Jones observed that an alkaline solution dissolved more than plain water.

Mr. W. E. Debenham found a small quantity of bromide in an eikonogen developer advantageous in keeping the shadows clear, and preferred boiled to distilled water for mixing the developer. Since the methylated spirit had been corrupted he had abandoned it, and used a small quantity of citric acid, which he used in the proportion of thirty grains to the ounce of pyro. He had kept such a pyro solution for four months, and it had only very slightly discoloured.

Mr. Chapman Jones asked what was the object in keeping pyro in solution?

Mr. Debenham thought it was convenient, and considered the dry-pyro plan objectionable, as one could not easily tell the amount of it used, and a little pyro made so much difference.

Mr. Chapman Jones regarded hydroquinone as the worst developer and the best stainer. It would bring out frilling better than any developer he knew of, the other parts of the formula being the same.

Mr. L. J. Montefiore had used hydroquinone a great deal, and never found the plates frill.

The Chairman said many workers complained of being unable to get clear shadows with hydroquinone. He had a five per cent. solution of hydroquinone in methylated spirit, water, and sulphite, which had kept good for about three years, and during the last four months had gone nearly black.

Mr. CHAPMAN JONES had found that hydroquinone and sodium carbonate would not develop an image on some plates.

Mr. DEBENHAM thought that the introduction of the caustic alkalies had helped the developer.

Mr. E. CLIFTON was of opinion that the caustic alkalies had done injury to the developer, as the lights were clogged up and the shadows not clear, the plates looking as if they were under-exposed. He thought hydroquinone better with carbonate of soda instead of caustic soda, the negatives acquiring more of the characteristics of pyro development.

Mr. CHAPMAN JONES could not see why eikonogen and hydroquinone should be mixed. With the eikonogen developer already mentioned he obtained any density he required.

Mr. CLIFTON said the quickest developer, and the one which gave most density, that he knew, was the one recommended by Messrs. Marion & Co. for exposures of one-thousandth of a second and under. It had to be used warm, but it brought out the image in a very short space of time. The formula was :—

Eikonogen	1 part.
Potassium carbonate	2 parts.
Sodium sulphite	5 ,,
Hot water	30 ,,

Mr. H. A. LAWRENCE had exposed two plates for the same time, and had attempted to develop one with ferrous oxalate, which, after an hour, gave no image; but the developer mentioned by Mr. Clifton gave a remarkably dense image.

Mr. W. BEDFORD preferred eikonogen to hydroquinone for bromide prints, as the latter was rather unmanageable. A small amount of bromide had a remarkable effect with the carbonates. Possibly caustic alkalies passed through the film much more rapidly than the carbonates, and tended to degrade the high lights, and provoke halation.

Mr. MONTEFIORE said he found rodinal good for portraits, but to get density he had to apply a hydroquinone developer afterwards.

Mr. CLIFTON said that he habitually used pyro, sulphite, and carbonate of soda, without bromide. For bromide paper he used Mr. Cowan's eikonogen formula, with lithium carbonate, very successfully. It did not answer for all makes of paper, as it left a lemon-coloured stain on some. The stain might be prevented by using a weak acid bath in the same way as with iron. Otherwise the developer got rid of the acid bath altogether, and the pictures were presumably more permanent, and the developer did not seem to give such clogged shadows as ferrous oxalate.

Mr. E. W. PARFITT had found that the anhydrous carbonates gave less stain than the ordinary carbonates. He inquired why Continental plates invariably fogged with ammonia.

Mr. DEBENHAM said that the same thing had been charged against American plates. He had, however, successfully developed the M. A. Seed Company's plates with ammonia. They were the most rapid plates he had ever used.

The meeting subsequently adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 21,—Mr. F. Bromley-Smith in the chair.

Messrs. A. Boucher and J. Avery were elected members of the Association.

The Chairman exhibited Furnell's shutter, which could be used either for time or instantaneous exposures.

A brief discussion as to loss of density in fixing, introduced by Mr. Teape at the previous meeting, took place, the influence of developer stains, and the fact that the negatives are looked at while still wet, being referred to as increasing apparent density.

MR. CAREY LEA ON "DISRUPTION OF THE SILVER HALOID MOLECULE BY MECHANICAL FORCE."

MR. A. HADDON drew attention to a paper on this subject by Mr. Carey Lea, in the current number of the *Philosophical Magazine*, which, at his suggestion, was read to the meeting. Commenting on Mr. Carey Lea's claims, Mr. Haddon complained that Captain Abney, Messrs. A. L. Henderson, Cowan, and Wellington had been ignored entirely by Mr. Lea in his references to his own experiments in producing a latent image by pressure. It was a matter which should be set right, and he thought that the whole credit of the experiment should not be claimed across the Atlantic. The paper was of great interest, and he (Mr. Haddon) did not wish to detract from what Mr. Carey Lea had done, but he thought the whole paper should be read to the members.

After the paper was read by Mr. G. W. Atkins, Mr. T. BOLAS observed that he thought Mr. Carey Lea should have mentioned the experiments of those who had discovered that a latent image was produced by pressure. At the same time, it seemed to him that what Mr. Lea had claimed as new was the disruption or blackening of silver chloride by pressure.

INTENSIFICATION.

The adjourned discussion on this subject was resumed by Mr. W. E. DEBENHAM, who said he could not understand the absence of a necessity for intensification which several members spoke of at a previous meeting. His own practice was frequently to make thin negatives and intensify them. He found that iodide of mercury followed by Schlippe's salt gave a greater amount of intensity than other mercury intensifiers, and the image did not change as others did. Intensification was often condemned because the negative was not properly fixed first. By the process he preferred it was shown at once whether the negative was fixed or not, which was not the case with other processes.

Mr. J. S. TEAPE had used Mr. Debenham's process years ago, and found that he got a great deal more density than he wished for, and the intensified image could not be reduced down. He preferred the two processes he had previously referred to, because, if too much density were obtained, it could be reduced.

Mr. DEBENHAM said that the mercury image could be reduced before it was "Schlipped," or reduction could be effected by any chloride process.

The meeting terminated after some further discussion.

North London Photographic Society.—July 19, Mr. J. Brewer in the chair.—The Secretary exhibited Messrs. Beck's "Frena" hand camera for films, and Messrs. Houghton's "Shuttle" camera for quarter-plates, which had been lent by the makers for that purpose. The action of the "Frena" in releasing the films after exposure, each film coming to the front in turn, was much admired, as also the various arrangements for sighting and exposing which have been well worked out in a convenient and practicable manner. The peculiar and special action of the "Shuttle" was fully explained, the simplicity and certainty of the changing movement being of especial interest, while the arrangements for focussing and exposing were thoroughly examined and appreciated. The opinion was strongly expressed that both cameras, each for its own special work, should take very high rank among the hand cameras now before the photographic world. Messrs. Beck's "Hynoe" printing frame was also introduced, and attracted much interest. Satisfactory reports were received of the Eastman chloride paper, most successful prints being shown, and the trials of the Ilford isochromatic plates had given great satisfaction, one especially fine negative of cherries being shown by Mr. Brewer. Mr. A. E. Smith showed pictures taken with lenses arranged as in an opera-glass, giving a telescopic result, and the Secretary showed cardboard dark slides made for use with films. No meetings during August.

North Middlesex Photographic Society.—July 25, Mr. F. Cherry in the chair.—About thirty-five members and friends were present, and three candidates for election were nominated. The Chairman introduced Mr. Thomas Bedding, who addressed the meeting on *Photography by Rule*. He contrasted the somewhat rule-of-thumb methods of the early workers with the present craze for innumerable formulæ, each requiring to be weighed and measured with scrupulous nicety, and each (though compounded to effect the same purpose) differing so widely in their constituent parts that neither science nor judgment seemed to have been consulted in constructing them. He expressed the opinion that the work produced in the early days had yet to be beaten, and that the general average was higher then than now. He pleaded for a cultivation of the reasoning powers based upon the worker's experiences, whether successes or failures, and deprecated an implicit trust being put in incomplete tables of exposures and fallible actinometers. He urged upon his audience that all could and ought to acquire technical excellence, upon which those who possessed artistic feeling might base their higher attempts. In the conversation that followed, Messrs. Beadle, Wall, Matthews, Pither, Johnson, Smith, and the Chairman took part. A vote of thanks was passed to Mr. Bedding for his paper, pregnant as it was with points of interest. Views taken at Kingsbury and Burnham Beeches were then voted upon. The latter competition was well entered for, and the vote of merit was accorded to Mr. Marchant. The remainder of the evening was devoted to technical questions and answers. The next meeting will be held on August 8, Mr. Marchant in the chair, when the various methods of harmonising harsh negatives will be discussed. Visitors welcome.

Hackney Photographic Society.—July 12, Mr. Beckett in the chair.—Work done on excursion to the Zoological Gardens was shown by Messrs. Sodeau, Dean, Nunn, Roder, and the Hon. Secretary. Mr. Pollard showed some prints of Tintern Abbey. He was asked if he had permission to photograph there, but he stated he had to pay 2*s.* 6*d.* to do so. Mr. REYNOLDS asked could he use an ordinary reducing solution for Sandell plates when necessary, as he could not manage that quoted! The CHAIRMAN preferred Howard Farmer's formula. The ferricyanide would get exhausted after a time. Mr. SODEAU said, in using too much ferricyanide, there would be a loss in the shadows. Mr. GOSLING asked if any one had obtained too much density with Ilford pyro formula. The CHAIRMAN observed that if that was so, too much pyro was used. He then called upon Mr. Hill to give a demonstration of the Cresco-Fylina process. Specimens of the process were passed round. The idea was that on immersion (into the above mentioned solution) of a positive or negative, the film would leave the plate and expand into nearly twice the size (demonstrated, with result that equal enlargement took place), and was then transferred to either an opal glass or paper in case of a positive, or glass for negative. The after process was precisely as would be the case of an ordinary print or negative. Mr. HILL stated that hydroquinone was the best developer to use for producing the original negative. Alum would act as a repellant, so was not advised, though citric acid could be used in pyro solution. Mr. BARKER asked if alkali would affect the stripping. Mr. HILL advised carbonates in preference to hydrates, though ammonia would enlarge perhaps better. Mr. POULSON wanted to know if, in drying, dust was likely to affect the plate; but was informed that it would be perhaps better to wash. Mr. GOSLING then gave a demonstration on Development. He advocated the old theme of one developer, and he preferred pyro-soda. He was an "Ilford" man, he said, as he had learnt all he knew from "Scraps," and consequently the plates, &c., he used, were of that firm's manufacture. He then developed a negative and lantern plate, but used too deep a light (in the general opinion of those present), which was constructed (for the occasion) out of a biscuit tin.

JULY 19, Mr. C. F. Hodges in the chair.—Mr. Nunn showed prints taken of the animals at the Zoo, and a plaster mould he had photographed gave six seconds, with rapid plate, *f*-16 by gaslight. A discussion on stickling (when using gelatino-chloride paper) was then taken up. Mr. REYNOLDS advised the use of a glass which was first heated and then putting on wax and rubbing with flannel until very little wax was left. The CHAIRMAN had used ebonite, and, as an emergency, the *papier-mâché* trays now so commonly used. Mr. DEAN said he thought if alum were used before squeegeeing to the plate prints would not stick. Mr. POULSON used ferrotype plate. The CHAIRMAN observed that people, as a rule, were too much in a hurry, and tried to peel them off before thoroughly dry. Mr. Dean showed a print from a mayfly which he had shut in a book and then photographed. The edges were stained on negative which had been developed with ferrous oxalate. Mr. BECKETT observed that he would put the negative direct into the fixing bath. Mr HENSLER asked how to stop up holes in negatives. Mr. FOULKES-WINKS said if thin negative he would varnish and then use the pencil. Mr. BECKETT said he would match the colour of the negative with colour. The CHAIRMAN

said he once lost part of a negative through the film getting torn. Mr. FOULKES-WINKS said he would advise, under such conditions, that a print be taken in platinum, then filling in with pencil, and then a reproduction taken. A question was then asked as to a good combined toning and fixing bath for aristotype prints. The Eastman last formula was recommended. Mr. SODEAN observed that corks in these bottles of solution were not to be recommended, as these solutions would not keep so well. A question was asked on intensifying with quinol. Mr. BECKETT said he used cyanide of silver as fixing; if not thoroughly washed, stains would result. Mr. WINKS said, when printing for platinum toning it would be best to print darker than usual. Mr. HENSLER then asked how to use saturated solution of hypo. Mr. SODEAN said, Take one ounce of solution, and one ounce of water. Dr. Colquhoun was nominated for membership. Mr. B. Foulkes-Winks then gave a paper on *Dodges*. Among the hints given were how to back plates, how to reduce with an ordinary camera, flatten silver prints (by passing paper-knife over the back, to cure pinholes and transparent spots (the former with retouching medium and pencil, the latter with a tint composed of black, blue, and crimson lake), blisters (pricking at back of print), and he advised any one using silver paper to use a sixty-grain bath.

Leytonstone Camera Club.—July 23, Outing to High Barnet, which was reached shortly after three o'clock, where the company were met by Mr. Hubert Elliott of the firm of Elliott & Sons, by whose kindness they were all provided with "Barnet" plates. Under the guidance of Mr. Elliott the company were piloted round Barnet and Hadley which are full of historical subjects. The stocks on the green, the High Stone, Monken Hadley Church, the old oak commemorating the scene of the battle of the Roses, Hadley Woods and various other spots having been visited, the party were invited to Mr. Elliott's mansion to a most sumptuous repast, and were next shown over the grounds, where boating on the lake and tennis were in full swing. Permission having been given by the host, several members had some excellent shots in the grounds. The company were next shown over the house. The pictures (some of which were of great value) were specially admired. Mr. and Mrs. J. J. Elliott having been thanked for the kind manner the Club had been received, the party were next invited to inspect the Barnet Plate Works, at the entrance of which they were met by the Manager, Mr. Birt Acres, who personally, in conjunction with Mr. Hubert Elliott, showed the whole of the premises, several of the managers of departments and others being in readiness to give special information of their respective departments as they in their turn were visited. To describe all that was seen would occupy more of your valuable paper than we dare do, as there would be little difficulty in taking several pages; but the carbon enlargements, life size, of figures and animals, and the Cadett machine for coating plates, for which the machinery in all departments was at work, were specially interesting. In fact, if all amateurs had seen, as we saw, the process that a plate has to go through from the glass crate to the packet of dry plates, they would marvel how we can possess them at the price we do. When the last department had been through, of which there had been about forty, we were surprised, although we had hurried through, it had taken two hours. Upwards of 100 plates were exposed.

Putney Photographic Society.—July 23, Outing.—The members met at Molesey Bridge and proceeded to the lock and weir, where some interesting views were taken. From Molesey the river bank was followed past Hampton Court and Thames Ditton to Surbiton. Saturday being the day of the Kingston Regatta, there was a rare opportunity for obtaining hand-camera negatives of the river crowded with pleasure craft of all kinds and sizes, not forgetting the City State barge, the "Maria Wood," so well known to all frequenters of the upper reaches of the river. Before proceeding on their holiday tours, several members tested plates and films of various makes, to compare their respective qualities, and much useful and practical information was obtained. Mr. Gorin exposed three of the new "Sandell" plates on the same subject—a clump of trees and bushes surrounding a pond; working in a fair diffused light at 5 p.m., with a stop of *f*·22, he gave one plate an exposure of about one-twentieth of a second, another one second, and the third twenty seconds. The negatives were developed with pyro and ammonia, and all three came out extremely well, the snap-shot being only slightly under-exposed, the one second correctly exposed, and the twenty seconds' exposure having none of the usual signs of extreme over-exposure; in fact, with more experience in the manipulation of these plates, and particularly in judging the density when developing, there can be little doubt that the under-exposure could have been greatly modified, and that the over-exposure would have yielded a negative in no way inferior to the apparently correct exposure of one second. Mr. Zachariasen carried out some experiments on the relative merits of plain and isochromatic films, the latter with and without a yellow screen. The subject chosen for the experiment contained yellow houses with red facings, pale blue blinds, blue slates, and light and heavy foliage in the fore and background. The results obtained fully confirmed previous experience, that for some subjects the isochromatic films have decided advantages, and that this is increased by the use of the yellow screen. The screen was of a light lemon colour, increasing the exposure four times, as proved by the following experiment. A half-plate film was exposed in camera divided by stereoscopic division, one-half being exposed for five seconds through a lens fitted with the yellow screen, the other half through a plain lens for one and a quarter second; the uncut film was then developed, the two negatives appeared at the same time, and development proceeded steadily. When taken out, both were equally developed, proving the relative correctness of the two exposures. A gas lantern, fitted with a two-feet burner, and provided with a deep ruby glass, eight inches by six inches, and a ground glass placed inside, was used during the development. This gave a soft and even illumination, quite ample for judging detail and density. Care was taken to carry on development at some four feet from the lantern, approaching it only to watch progress. The edges of the films kept perfectly clear; it is therefore obvious that no fogging took place, and that the objection occasionally raised to the use of isochromatic plates and films, that they must be developed in a very feeble light, is not a serious inconvenience when the bright light is of the right quality and carefully used. The next outing of the Society will take place at Carshalton, on August 6.

South London Photographic Society.—July 18, Mr. L. H. Greaves in the chair.—Mr. J. Miller read a paper *On Photographic Dodges and Combination Printing*. After a few hints as as to the practical use of the camera, Mr. Miller advocated the use of the following developer, which he had used for a considerable period in Great Britain and South Africa, and with it had been able to develop plates of any make: A.—Sulphite of soda, 300 grains; citric acid, 20 grains; pyro, 100 grains; distilled water, rain water, or boiled water, 16 ounces. dissolve ingredients in order named, each to be dissolved before the next is added. B.—Bromide of potassium, 50 grains; water, 60 ounces. C.—Liquor ammoniæ ·880, 2 drachms; water, 16 ounces. For normal exposure take half an ounce each of A and B. In another measure take half an ounce of C, adding it to A and B immediately before development. For under-exposure use less of B and more of C; for over-exposure use less of C and more of B. In cases of great contrast reduce the quantity of A. The lecturer stated that he considered every negative, no matter how good, was capable of improvement, and proceeded to explain how this could be effected. Before anything was done he always took a rough proof from the negative. Matt varnish was useful to increase contrasts, as it could easily be scraped away from any part which it was desired to print more deeply. It could also be used to retard or keep back any part that printed too deeply, and afforded a fair surface to retouch or stump upon. Tissue paper without any grain, such as is used by draughtsmen, could be employed to effect similar results, by fastening it on the back of the negative with starch. Portions of this could be cut out with a knife and afterwards removed easily after damping. The paper could be made transparent by applying the following mixture with a brush, viz., Canada balsam dissolved in benzine, using sufficient of the former to prevent the solution spreading when used, and afterwards adding three or four drops of castor oil. Portions of negatives could be blocked out by the application of lamp-black to the paper. Mr. Miller advised the use of a piece of discoloured silver paper in the frame when making prints to prevent discolouration and contraction. Prints should be washed and toned as quickly as possible. The faces should be sponged before being placed in the toning bath, as this facilitates toning. The bath was made up as follows: Acetate of soda, 340 grains; bicarbonate of soda, 35 grains; chloride of gold, 4 grains; distilled or boiled water, 80 ounces. Keep for a day or two before using. The various methods of producing combination prints on silver paper were dealt with at length. To remove the discolouration from the edges of old plates, and for reduction, the lecturer advocated the following, viz., iodine dissolved in water, using a few crystals of bromide of potassium to bring about dissolution, and adding same to the hypo bath. The solution of iodine must not be too strong.

Brixton and Clapham Camera Club.—July 19, Dr. Reynolds (President) in the chair.—Some interesting questions were taken from the box and discussed, one of them being, "Is it necessary that the axis of the lens should be at right angles to the plate?" Upon this opinion was fairly evenly divided, but probably the majority considered that it was not absolutely necessary. Another question, which is of interest at this season of the year, was, "For sea pictures is it advisable to use a quick plate and a small stop, or a slow plate and a large stop?" and the meeting seemed to favour the latter view. A third question was, "Does any member find the Ilford 'P.O.P.' paper tone rather slowly?" This was answered in the affirmative. Subsequently the Club lantern was used to throw upon the screen some slides contributed by Mr. F. Goldby and the Hon. Secretary.

Newcastle-on-Tyne and Northern Counties' Photographic Association.—July 14, a party of sixteen members had an outdoor meeting down the Tyne. The party journeyed by the one o'clock boat from Newcastle Quayside to North Shields, several exposures being made at the shipping on the way down. On arrival at the Fish Quay, the number of cameras on the scene caused a deal of excitement amongst the fisher folk, several of them being very anxious to be photographed. After exposing a number of plates on the various groups, the party crossed the river to South Shields, when Mr. William Parry, who ably acted as leader, photographed the members. After tea Mr. Parry kindly showed them over his studios and printing rooms. A most enjoyable day was spent, and the weather was all that could be desired.

Correspondence.

LOSS OF DENSITY IN FIXING.

To the EDITOR.

SIR,—I am very glad to see your leader in the current JOURNAL on the question whether the hypo bath can really exert any solvent action on the negative image during fixation. I always dismissed the idea of it being possible, seeing how very much this seemingly innocent and dilute solution differs from any known solvent of silver.

I fear I must differ from your remark that "a wet negative shows greater apparent density than a dry one." My experience would put it just the other way, for frequently a negative which—when developed, fixed, and washed—has been considered too thin, and is consequently put aside for intensification, when thoroughly dry has been found to be of ample printing density. Possibly the monochromatic nature of the dark-room illuminant may sometimes account for this.

There is another curious point about gelatine negatives that I have never seen mentioned or noticed anywhere. This is, the difference in intensity and vigour of one intensified immediately after fixing and washing and one which has been allowed to dry first, the latter being by far the better of the two.

The actual reason of this I do not know, but it seems certain that some molecular change takes place in the film in the process of desiccation.—I am, yours, &c., A. HOWARD BENHAM, A.M.I.C.E.

4, *Albert-terrace, Albert-road, Regent's Park, N.W., July* 22, 1892.

THE STOPS OF FRONT COMBINATIONS.

To the EDITOR.

SIR,—Will you kindly tell me how to estimate the value of the stops—in other words, how to estimate the exposure when using the front lens of a rectilinear combination as a single lens, as suggested in your leading article of June 24? I tried it yesterday, using the front lens of my nine-inch Ross's universal symmetrical (the camera not having sufficient draw to use the back lens), and gave four times the exposure I should have done using the same stop with the complete lens, which I thought was theoretically what I should require. This, however, gave over-exposure, and I think three times would have been quite sufficient.

It seems to me that, if one was sure of the exposures, it might sometimes be very convenient to use the lens in this way for distant views.—I am, yours, &c. J. H.

July 19, 1892.

[We have dealt with our correspondent's communication in another part of the JOURNAL.—ED.]

SPEED OF PLATES.

To the EDITOR.

SIR,—The outcome of the two letters of Mr. Sterry and Mr. Phillips is to draw attention to the one essential definition of sensitiveness which Messrs. Hurter & Driffield have adopted in their method. It is to find the first term of a regular series of exposures in which the resulting densities increase by regular increments. Now, this method leaves entirely out of the question whether this correct scale of graduation has sufficient opacity in the highest terms of its scale to provide practical printing "density" in a negative. The practical consequence is that, when Messrs. Hurter & Driffield's method is applied to certain classes of emulsions, it indicates a sensitiveness which is not substantiated when the plate is exposed in the camera, and a practical printing opacity becomes a *sine quâ non*.

For instance, Messrs. Hurter & Driffield, in their original paper to the Society of Chemical Industries, mention that they had found the Ilford red label to be the quickest plate they had tried.

Now, it happened that when this paper came out I had been comparing in the camera different brands of plates, and found that the plate named was by no means so sensitive, from a *practical* point of view, as most of the other rapid brands of plates. It is true that it gave detail (what Messrs. Hurter & Driffield would call correct gradation) with short exposure, but to get printing opacity (density, as a photographer calls it) a considerably longer exposure had to be given.

I feel quite free in mentioning this instance, as the Britannia Works Company have lately superseded the plate in question by a *new* Ilford red label plate, which is entirely different in "density"-giving capability, and consequently is twice as rapid as the old brand.

Fortunately Mr. Sterry, in his table of examples, has provided me with a means of illustrating this point. I must first mention that, although Messrs. Hurter & Driffield are obliged to measure actual *opacities* in their instrument, these opacities are translated into physical *densities* on the scale of the instrument. This peculiarity of the system has given rise to much inconvenience and misunderstanding, and, to make the figures understood by practical photographers, I have translated Mr. Sterry's densities back into opacities.

	1	2	3	4
1½ C.M.S.	1·23	1·38	2	1·45
2½ ,, ...	2·14	2·96	3·17	2·7
5 ,, ...	4·8	7·25	5·5	5·9
10 ,, ...	11·5	18·5	10·5	13·5
20 ,, ...	28	44	16·5	29·5
40 ,, ...	58	84	21·5	60·5
80 ,, ...	159	165	27·5	94
160 ,, ...	166	170	35·5	164
Actinograph speed	23	31	52	31

In order that the reader may grasp the meaning of the above figures, I should mention that in a negative required to print a complete scale of tones from white to black on platinum paper, and in which the black is represented by clear glass, the proper opacity for white is 54. In other words, if we find the greatest amount of light to which platinum paper can be exposed, and still be white when developed, exactly 54 times this amount of light is required to print dead black on the same paper.

Now, in photographing a group of white objects with a full scale of tones down to black, it would be necessary that the highest lights in the negative should be represented by an opacity of 54.

On referring to Mr. Sterry's trials, it will be seen that in No. 1 plate an exposure of 40 seconds gave an opacity of 58 (sufficiently near for our purpose); but, taking No. 3 plate, which the actinograph method makes nearly twice as sensitive as No. 1, it will be seen that the same exposure (40 seconds) only gives an opacity of 21·5 with the same development. It therefore follows that, if No. 1 and No. 3 plates were exposed for the same time on the group of white objects, the exposure being just right to give a maximum opacity in the case of No. 1 of 58, the highest opacity in the No. 3 plate would be only 21·5, and the negative would be too thin to give a correct print, and yet Messrs. Hurter & Driffield's method would lead the photographer to suppose that No. 3 plate only requires half the exposure of No. 1.

The fact is that No. 3 plate is coated with a poor, thin emulsion of detail-giving capacity, but wofully short of density-giving power, and in ascertaining its *practical* sensitiveness a very considerable compromise would have to be made to get anything approaching printing density, and I should prefer not to use it at all for making negatives. There is very little that is absolute about the science of photography, and probably the final method of ascertaining the sensitiveness of plates may be something of a compromise between the "scale of graduation method" and the "density-giving" method.

I still hold to my original objection to Messrs. Hurter & Driffield's method, that, giving a white light scale of sensitiveness, it can not express the average camera sensitiveness of different makes of plates. My objection to the standard candle I stated to be a very minor point. Perhaps it is as reliable a standard as any other.

Would Mr. Sterry kindly say what he means by the term development factor? I find no mention of it in Messrs. Hurter & Driffield's paper.—I am, yours, &c., ALFRED WATKINS.

Hereford, July 24, 1892.

FUNGOID GROWTHS ON LANTERN SLIDES—FUGACITY OF BROMIDE PRINTS IN HUMID CLIMATES.

To the EDITOR.

SIR,—You will, no doubt, remember my sending you several specimens of lantern slides (in 1889 or 1890) to show the fungus growth on the covering glasses. I am now sending you through my brother at home two specimens of chloride plates of English manufacture which show the effect of this climate. I am sorry I cannot say what make they are, but they are specimens of what is going wrong with a large batch of chloride transparencies out here. You will notice, 1, that the film splits and leaves the glass; 2, that a fungus growth has appeared between the glass and the film. This may possibly account for the film leaving the glass. I think the glass used must be French white, which grows fungus here faster than any other kind.

I draw your attention to the above because other makes give results which stand this climate perfectly. Whatever claims the chloride plates have to priority, they are no use here.

Last year I sampled several makes of chloride plates purchased here, and every plate developed dead black all over with hardly a sign of the picture. Several others tried them with the same result and we let the plates alone. I have recently received a few boxes of rapid and slow lantern plates through my brother, and the slow plates develop dead black without exposure to white light. Others confirm my results, and I am now convinced that the plates will not stand the change in climate. I should like to know whether these plates, if kept at a temperature of say 90° F. for some time in England, give the same results. Rapid chloride stand much better, but also lose much of their proper qualities. If the above heat test causes no change, the air should be damped. Our humidity at present ranges from 10 to 95 per cent.

While on the subject of the Indian climate, did you read my article in the *Indian Journal* some months ago on the destruction of bromide prints by keeping them face to face with platinotypes? After two years my bromides have almost disappeared, while the platinotypes stand perfectly. This is undoubtedly owing to something peculiar, as the platinotype picture prints itself on the bromide by destruction. If the platinotype or bromide were imperfectly treated the destructive action would take place all over. I feel sure it is a chemical action between the platinum and silver requiring a high temperature, excessive humidity of air, and gentle pressure to secure contact.—I am, yours, &c., JOHN S. GLADSTONE.

Gillander House, Calcutta, June 21, 1892.

[We have commented upon our correspondent's interesting communication elsewhere.—ED.]

ENLARGEMENT.

To the EDITOR.

SIR,—The difficulty raised by your correspondent, Ethel Constance May, is not so great as she thinks. From the formula $\frac{D}{f+x} = \frac{D-f}{f} = \frac{1}{n}$

Where x = increment of focal length, and n = number of times linear enlargement, it is easily seen that $\frac{f+x}{f} = n+1$.

Hence, to obtain the new focal value of a stop, we multiply the denominator of its former focal value by $n+1$. Thus, if $n=3$, f-8 becomes f-32, requiring sixteen times the exposure for f-8. Of course for reduction n is fractional.—I am, yours, &c., CLIFFORD E. F. NASH.

Cheltenham, July 25, 1892.

Exchange Column.

*** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Exchange Chambers' 15×12 W. A. R., new, for good whole-plate modern camera and three backs.—F. & H. Dann, Photographers, Reading.

Will exchange 15×12 Ross' landscape lens for whole-plate wide-angle rectilinear, any good make.—Address, E. J. Lester, 7, Forest Hill-road, S.E.

Pneumatic safety bicycle, balls throughout, Dunlop tyres, new last summer, in exchange for 10×8 view camera, three dark slides, and tripod or lens.—Address, T. Wilson, 44, Swinley-lane, Wigan.

Will exchange Franks' Presto hand camera, pocket microscope and slides, pantagraph, and shorthand books, for Shew's guinea pocket camera.—Address, J. F. Teague, 44, Leighton-lane, Leeds.

Fifty-two inch cyclometer by Lége, adjustable to hub or spokes; exchange for Watkins' exposure meter or Thornton-Pickard shutter (half-plate).—Address, H. G. Perring, 6, Newington Green-road, N.

Will exchange 8×5 new Ross' Universal symmetrical lens, for Ross' No. 2 Universal lens, or Dallmeyer's 3D., or 8½×6½ Dallmeyer's patent rapid rectilinear lens.—Address, J. W. Coubi, Northgate, Hartlepool East.

Exchange background (distempered), 8 ft.×7 ft., Tylar's current producer and discharger, hand camera (carries six quarter-plates in three double slides), and quantity of photographic literature, for backgrounds (interior or exterior), or rustic accessories.—Address, Fred. C. D. Hurd, Photographer, Shepton Mallet.

Answers to Correspondents.

All matters for the text portion of this Journal, *including queries for "Answers" and "Exchanges," must be addressed to* "The Editor," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** Communications relating to Advertisements and general business affairs must be addressed to* "Henry Greenwood & Co.," *2, York-street, Covent Garden, London.*

W. Bramston.—No; there is no "assistants' union" in existence now.

Reducer.—Potassium ferrocyanide does not react with metallic silver, hence your failure.

L. R. Rice (Bridgend).—No; hypo is not poisonous. Your informant was probably thinking of potassium cyanide.

Palladium.—The new Eastman gelatino-chloride printing-out paper is amenable to the action of the burnisher just the same as albumenised paper.

R. Cameron.—The Cosmoramic stereoscope is practically the same as the original Brewster instrument, the wooden body being square instead of a pyramidal shape.

D. Fisher.—Yes; reversed negatives are sometimes taken by exposing the plate through its glass side without any appreciable loss of sharpness being found to result.

Alec (Perth).—It may be that the slowness of the fixing of the plates arises from the strength of the hyposulphite solution. Instead of using a saturated solution try the effect of slightly diluting it.

Lost says: "Could you give me the quantities of soap and alcohol for making a lubricator for burnishing silver prints?"—Two grains of Castile soap to the ounce of alcohol would form a suitable proportion.

Silendo.—Hydroquinone, or hydrokinone ($C_6H_6O_2$) is known to chemists by either of the names here given. The full chemical name of eikonogen is, we believe, Amido-B-naphthol-B-monosulphate of sodium.

Geo. Knight.—There is a work on *Collotype* by Dr. Julius Schnauss (translated by Mr. E. C. Middleton, and published by Messrs. Iliffe & Son, of St. Bride-street, E.C.), which is probably what you require.

Landscape (Brompton-road).—This correspondent asks us whether permission to photograph in the royal or public parks enables one to sell the views so obtained. We know of no regulation to the contrary. Do any of our readers?

Aretas (Stockwell).—It has, we believe, been proved that the electric spark, given off when either cut or rollable films which have adhered are separated by a little force, is sufficient to fog the sensitive layer. Yours is no uncommon experience.

A. C. W.—There are other methods of blackening an image bleached with mercuric chloride than those with ammonia, sodium sulphite, or hypo. For instance, an ordinary alkaline developer may be used to the advantage, probably, of more ultimate density than with either of the foregoing.

T. D. (Catford).—You over-estimate our capabilities in asking us to tell you "the reason why" you "cannot produce as good a negative as that which was shown at ——'s as a specimen negative on their plates." Send us one or two of your failures, and we may then be able to indicate the cause of them.

Thiosulphate.—Fix your negatives in this way: place them in the old hypo bath until they are cleared of the white bromide, which is ascertained by looking at the back; then transfer them for a few minutes to a fresh hypo bath and afterwards wash. When the first bath is exhausted pour it away for precipitation of the silver and let the second one take its place, a fresh one being made to supply its place. This will fulfil your ideas of economy.

Snap-shot.—The examples for a beginner in hand-camera work are above the average in point of merit. It is a moot point, however, whether such pictures as yours—notably that of a group of men emerging from a public-house in a highly "elevated" condition—are quite permissible. The indiscriminate use of the hand camera is to be deplored.

Helios.—Possibly small particles of wood were left in the rebates of your slides, and these may have adhered to the plates during exposure, and so have caused the transparent spots you speak of. Most beginners omit the precaution of well dusting the camera and slides before using them, an operation which is highly necessary with the cheaper forms of apparatus.

A. H. says: "Would you kindly tell me whether there any works on the preparation of dry plates, or where I could get the necessary information?"—The British Journal of Photography and its Almanac of former years contain information on the subject of dry-plate making of a highly complete and valuable character, which would certainly repay our correspondent for the trouble of searching. Abney's *Emulsions* is an excellent book on the subject, chiefly from the experimentalist's point of view. There is also a work in German by, we believe, Eder, which goes into the *minutiæ* of the process for manufacturing purposes.

Messrs. Philipp, Munson, & Phelps, of 7, Beekman-street, New York, write: "We have occasion to inquire into the history of the art of photography, particularly with reference to the use of gelatino-bromide emulsion upon paper for positives. We write to ask you if you can refer us to any full description of the use of gelatino-bromide emulsion paper for positives prior to the year 1879, or can give us any information which may possibly result in our finding such a publication. We may say that we have fully examined The British Journal of Photography, *Photographic News*, *Photographie News* Almanac, and The British Journal Photographic Almanac, and are familiar with references found in those magazines to these subjects. Any information with regard to the early history of gelatino-bromide emulsion as applied to paper will be gratefully received by us. We are in search of Dr. Monckhoven's *Treatise on Photography*, published about 1879, and also of a publication entitled the *Argentic Gelatino-Bromide Workers' Guide*, published at London about 1880 by Morgan & Co. If you happen to know where either of these works can be procured, we shall be obliged to you for the information."—We do not think that any such description or publication as our correspondents require is in existence. If they have digested what has appeared in The British Journal of Photography and its Almanac on the subject, they have secured all the information available; but, lest they may have overlooked it, we may refer them to our article in the Almanac for 1875 which deals with paper as a support for gelatino-bromide of silver, suitable, of course, for either negative or positive purposes. A further fact of possible interest in connexion with this matter, and one generally, if not entirely, overlooked nowadays, is that, in July, 1879, Mr. J. W. Swan obtained a patent (2968, July 22, 1879) for what was, and is, practically the modern process of gelatino-bromide of silver printing for developed positives. Monckhoven's *Treatise* is not now obtainable, but possibly Messrs. Morgan & Kidd, of Kew Foot-road, Richmond, London, S.W., may be able to supply our correspondents with a copy of the *Argentic Gelatino-Bromide Workers' Guide*, published in 1880.

Photographic Club.—August 3, *Outdoor Experiences*. 10, *Opal Pictures*. Bank Holiday outing, Berkhampstead; train from Euston at fifteen minutes past ten.

Herr Rudolf Mayer Nachf, of Munsterstrasse, Friburg, informs us that he has a dark room which may be used free by amateur and professional photographers visiting that town.

London and Provincial Photographic Association.—August 4, Report of the delegates to the Photographic Convention of the United Kingdom, held at Edinburgh. 11, Members' open night.

The freehold of the land and premises occupied by the Autotype Company at Ealing Dean, formerly part of the estate of the late Mr. Benyon-Winsor, was recently put up for sale by auction. The purchasers were the Autotype Company.

In our notice of the "Sandell" plates last week, we inadvertently referred to the "General" plate as the "General rapidity," thus implying that there was a difference of rapidity between it and the "Especial" plate. Both plates are, however, of equal rapidity.

Photographers often desire to take pictures of the interiors of the English cathedrals, and doubtless the terms upon which the necessary permissions may be obtained would be of general interest. Perhaps those of our readers who have had experience of this kind of work can enlighten us. In the case of Norwich Cathedral we are informed that the Dean grants permission on the following terms:—2*s.* 6*d.* per day, 5*s.* for two days, 20*s.* for a week, a fee of 1*s.* 6*d.* being charged in addition by the "sub-sacrist" for his attendance. As these figures read, it would be cheaper, as our friend remarked to us, to pay daily than weekly. The charges appear to us rather high, but they are eclipsed by the guinea per day which, we are told, is exacted by the authorities of Hereford Cathedral.

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1683. Vol. XXXIX.—AUGUST 5, 1892.

THE DECAY OF PROFESSIONAL PHOTOGRAPHY.

The apprenticeship system in modern professional photography was subjected to some destructive criticism at the hands of Mr. Farmer in the course of the paper on "Deficiencies in the Early Training of Photographers," which he contributed to the Edinburgh Convention. That paper and the discussion that followed it are of considerable utilitarian value. The author has an undoubted knowledge of his subject, gained by experience and observation as an instructor in photography, and the speakers in the course of the discussion were representative men whose views on the points raised command attention.

In condemning the apprenticeship system in professional photography, and in adducing his well-recognised reasons why that system should disappear or be modified, Mr. Farmer indicates the existence of a state of things which if not dealt with ere long must undoubtedly react to the injury of photography as a profession in the near future.

Professional photography at the present time is admittedly not in a flourishing condition, and the causes commonly assigned for the depression include, of course, bad trade, severe competition, and the influence of the once-despised but now potent amateur. We fear, however, that a photographer himself is more often the cause of his own unfortunate position than are those we have just named. No parent in his senses would dream of apprenticing a lad to an ordinary photographer nowadays, and the reason for this strikes us as being equally available as an explanation of the ordinary photographer's lamentations over the smallness of his profits. In the establishment of such a man a clever, intelligent lad of fifteen or sixteen might pick up in the course of a year or so all that was to be learnt there, and probably a little more than his principal was competent to teach him.

For what is to be learnt in ninety-nine studios out of a hundred beyond lighting, posing, exposure, and development? The retouching, as one may gather from our advertisement columns, is generally put out; the printing is more frequently executed by trade printers than not, and in cases to the contrary is chiefly confined to one, or, at most, two processes. Again, photographers who do their own enlargements are remarkably few; and, indeed, to sum up the average photographer's business, it may safely be laid down that most, if not all, the work and its numerous varieties is "put out." In such cases, which, we believe, form the majority, we submit that the apprenticeship system is bound to fail on account of the inability of the principal to impart any but a limited range of practical knowledge to the youth he is supposed to teach.

But this is not all. The mere taking of the negative is often, if not exactly "put out" at least "farmed," that is, supposing a portrait photographer to have an order for a landscape embracing a house, a piece of architecture pure and simple an interior, or an *objet d'art*, &c., to photograph, he probably prefers not to undertake it himself, but to employ another photographer, who makes a speciality of such kinds of work, to produce the negatives for him. The growth of specialism in modern photography leaves the average professional photographer much in the position of a mere commercialist, with just the necessary superficial technical knowledge that will enable him to conduct his business with more or less success.

Of course, there are exceptions to the picture we are drawing, but we do not think they are sufficiently numerous to shake the accuracy of the outline. The race of photographers who collodionised and sensitised their own plates, sensitised their own papers, retouched their own negatives, did their own printing and enlargements, and in short carried on in their own establishments most if not all the work which to-day is "given out," does not seem likely to be perpetuated among the professionals of the present time. We should have nothing to urge in disfavour of this practice of "putting out" work if we could feel assured that it did not operate adversely to a photographer by depriving him of considerable practical knowledge, and placing an obstacle in the way of his transmitting such knowledge to others. These, however, are the two unfortunate effects which the system appears to us to have.

We regret very much to reflect that, in the endeavour to impart to a youth the necessary training and practical experience in order to qualify him as a thoroughly well-grounded, and, what is called, "all-round" professional photographer, it should be essential that he should not be placed at the mercy of one who should be his natural preceptor—a professional photographer—but apparently there is no help for it. The future of professional photography depends, fortunately, not upon professionals themselves, otherwise the outlook would be inexpressibly dreary, but upon the facilities provided for enabling young fellows to practically qualify themselves on the lines laid down by Mr. Farmer. Few as those facilities are at present, we are convinced they will not be without great influence for good in the near future, and we hope to witness a considerable extension of them.

CLEARING SOLUTIONS.

In writing last week of the "Alum and Hypo Fixing Bath," we showed how it combined with its function of fixing that of clearing the film, if not also of hardening it, an economy of labour which, under some circumstances, may prove extremely useful. Comparatively few, however, employ this compound bath, the great majority, simply as a matter of practice rather than one of preference, applying the clearing and hardening solutions,

Improving Negatives.—In a paper read before one of the metropolitan Societies, the author of it said that he considered every negative, however good it might be, was capable of improvement. In this opinion he is quite correct. We well remember some years ago being present at a demonstration of the carbon process by Mr. Lambert, when some very excellent portrait negatives were handed to him, with silver prints therefrom. The first thing he did was to improve the negatives. This he did by backing them with thin transluscent paper—*papier minéral*—and then working on that with a stump lightly charged with plumbago. Although the work only occupied him a minute or two for each, the effect was truly wonderful, although, as we have just said, the negatives, at first, were considered excellent. It is a little surprising that amateurs of the present day do so little in dodging their negatives, particularly as it requires no particular skill, and, moreover, is quickly done. For small negatives, matt varnish is preferable to paper, and it has the advantage of not discolouring with age, and is not so liable to injury. The varnish should, of course, be applied to the back of the negative. Those who have never tried will be surprised with what can be effected, and the ease with which it is done. If a shadow requires strengthening, the varnish is roughly scraped away. If lights require vigour, a few touches with a pencil, or a stump and black lead, is all that is necessary. If the contrasts in the negative are too great, they may be ameliorated by removing the varnish from the lights and leaving it on the shadows, or, if necessary, stumping the deepest ones over with the plumbago.

CONVENTION JOTTINGS.—II.

The Group.—In the earliest ages of the art, when exposures were measured by minutes, and sometimes many of them, it was an easy matter for the photographer when taking a group to uncap his lens, and then rush forward and take his position previously determined upon, afterwards darting to the camera and capping the lens without any trace of the movement showing in the picture. But in these times, and with plates of exquisite sensitiveness, methods of this nature cannot be had recourse to, the photographer must stand by his camera to touch the trigger at the moment he observes becoming quiet and expression on his subjects. This accounts for the absence of some prominent men from Convention groups, men who are on the spot, yet cannot be induced to trust their cameras into the hands of assistants even for the few moments requisite. It need scarcely be said that when a large and important group, like that of the Convention, is posed, numerous photographers other than the legitimately appointed one (Mr. Alexander Ayton, jun., in this instance) are anxious to have a shot.

The New Premises of the Edinburgh Society.—We visited the new premises of the Edinburgh Photographic Society, situated in North Castle-street, directly opposite the town residence of Sir Walter Scott. As a detailed account of it appeared in this JOURNAL a few months ago, we need now only say that it speaks much for the enterprise of the Society that on such a small member's subscription it has acquired such central, commodious, and well-fitted-up premises. Here are smoking, reading, general meeting, experimental, developing, and no end of other rooms. The library was in course of being arranged when we called.

The Apparatus.—As we stated elsewhere, the display of goods exhibited on the tables at Convention headquarters was only in progress when our first parcel from there was dispatched. Among the things which were *in situ* the day following were a peculiar little hand camera by Shew & Co., the action of which was unlike anything we had previously seen. It had no baseboard, the body being distended by internal mechanism; but, by pressing the top and bottom by thumb and finger, it instantly collapsed into the smallest conceivable space.

Careless Storage of Cameras in Travelling.—Said a lady, whose watchful eye was taking stock of the debarkation on the railway platform of a large collection of handbags, portmanteau, and photographic apparatus generally at a post-Convention outing at Callander, "Which of you gentlemen have been so insane as to have entrusted your cameras to the guard's van? I always thought you considered your cameras so sacred as to treat them as tenderly as we treat babies in arms, and here are two among the packages in the van. It's incredible!" Two of the large party, composed of ladies and gentlemen in nearly equal numbers, pleaded guilty to the delicate impeachment—one of them a well-known member who hails from Chesterfield, the other being ourself. But there's something to be said in extenuation, especially when one carries two cameras, one of which, as in our case, was somewhat large, and fitted with a roll-holder capable of containing several dozens of "exposures." When, in a crowded train, ten people have to find accommodation in one compartment, it is emphatically a case of *place aux dames*, and those who travel with ladies know what this implies.

Focussing Without a Screen.—Having next day exhausted the supply of plates belonging to our stereoscopic camera, on reminiscences of the Pass and Falls of Leny, bits of Ben Ledi, Loch Lubnaig, and the rich pictorial scenes in that locality, we had to fall back on the large camera, with roll-holder, for the outing the following day, when our party, filling two large waggons, drove through the Trossachs' Pass to the beautiful Loch Katrine. Unpacking the camera for the first time since the guard's van episode, we became painfully aware that its ground glass had been smashed into a state of "smithereens." What was to be done? The day was bright and calm, and all nature was lovely, but the nearest glazier's shop was many miles away, and even there they would not be likely to keep focussing screens in stock. A fragment, the size of two fingers, was secured, and held as near as could be guessed in the plane of the rebate of the frame, and upon this the focus of the middle distance was obtained with the full aperture of the lens, the iris diaphragm being then closed as far as it would go. The location of the subjects on the plate was ascertained by squinting along the tail-board of the camera, and, singular to relate, all the negatives taken that day by this once-for-all focussing are quite sharp. A piece of geometrically flowered glass was next day fitted into the camera, and formed an extraordinary, but on the whole a serviceable, substitute for a ground glass.

A Home from Home.—The Trossach Pass has had a certain reputation extending for ages back. This reputation savours of the "stand-and-deliver!" order of language. The most recent development or evolution of the sentiments entertained by men of the Roderick Vich Alpin Dhu calibre is reported to be associated with the hostelries of the district, where "Thy name and purpose, Saxon, stand!" more recently assumed the more civilised rendering of "Here's your bill, sir," delivered on a silver salver by a white-neck-tied waiter. This, from personal experience, we affirm to be a slander, so far, at any rate, as Callander is concerned, where we domiciled in the Callander Caledonian Temperance Hotel, the most beautiful and best-appointed of all the hotels we have seen in the Highlands, where the charges for tea, bed, and breakfast are scheduled as at five shillings, with ninepence for attendance. We never like to advertise hotels, but it is due to the present and reformed character of this town, which forms the key-note to the Roderick Dhu parts of the Highlands, that we should here give a new and more pleasant rendering of the "stand-and-deliver" idea so long prevalent.

ON THE SELECTION OF VIEWS.

I.

THE season has now arrived when genial weather and all the attractions of a pleasant English summer tempt photographers, both amateur and professional, to start in search of pictures, not only in the most favoured part of this country but in the less picturesque districts; for where are not pictures to be found by those who can see?

So universal has become the practice of this beautiful art both for business and pleasure, especially the latter, that it has become rather a rule, than an exception, that some one or other of every family

will dabble more or less in it. It seems so very easy for beginners to select views and bits to photograph providing they are fortunately situated with regard to their surroundings, that any hints as to finding suitable ones may seem superfluous and unnecessary.

It is not until the negative is taken, developed, and probably printed that it is discovered, although the view was so promising, the results are disappointing and very different from what was anticipated, coming out neither artistic nor pleasing, both of which qualities seemed assured when the picture was seen on the focussing screen. Many photographers cannot realise that it rests principally with themselves to produce either things of beauty or of no value almost irrespective of the scene, for the most unpromising in clever hands will supply beautiful pictures, examples of which we have every day. A view of itself is only so much material from which a proper selection has to be made, and the value of that selection will depend entirely on the perceptions and artistic ability of the photographer himself. To photograph a landscape without due consideration, simply because it appears beautiful to the eye, is to court failure. Supposing a number of choice works of art were put together indiscriminately and photographed, they would make but a sorry picture, but if properly arranged and lighted would be individually beautiful; so it is with landscapes; an aggregation of beautiful things that require care and discrimination in selecting; without, they are represented as a mere unsatisfactory jumble, the good qualities and attractive points are lost or with difficulty distinguished, the general result being unpicturesque and unsatisfying. The fault of most beginners, and some others too who have had more experience, is to attempt too much, that is, to represent too much on each plate, hence the hankering after wide-angle lenses. The undesirableness of using instruments of this class has been insisted on times without number, but there seems to be something fascinating in the power of including a tremendously wide angle that the advice to use less inclusive lenses has to be frequently repeated.

There is no disputing that wide-angle lenses are of great use in certain cases, in fact I do not know how we could get on very well without them, but for ordinary landscapes, I may say, they are never required. My advice is to always use as small an angle lens as consistent with the requirements of the subject; by doing so, the, artistic effect will be better. If, for instance, a ten-inch lens will include all required, do not use an eight-inch one; but if the photographer has a good series of lenses, and possesses artistic ability, he will soon see which will be of the most suitable focus and give the most pleasing results. However, this is not a dissertation on lenses, but how to select the best points for them to be used upon.

It does not follow, by any means, that the most beautiful landscape to the eye is the best for photographic representation, it is frequently the very opposite. Before setting to work, the photographer should critically examine the view he intends taking, gauging its suitability, independent of its colour, which often exercises a distracting influence, its examination through a piece of neutral-coloured glass is a help in this direction, and enables him to note the effect of the light and shade in a more correct manner than he otherwise could, until by practice he can estimate its proper photographic value by his unassisted eyesight. When thoroughly master of this, a great step has been taken towards the production of good work. It will be found that, in addition to the disturbing influence of general colour, local colour will have to be taken into account: as an example, a road, with a red brick building on one side, a bright sunshine, and on the other a whitewashed cottage in the shade. The probability is the white cottage and shadow will come out lighter than the red brick in the sunshine, owing to its local colour. This is but an instance; numerous cases, with varying degrees of effect, are frequently cropping up, and it is only experience that will afford the necessary knowledge to estimate their values truly. Still, by having some idea of the influence of local colour, very glaring mistakes may be avoided. Even with old hands, local colour will sometimes upset the balance of a composition, which has to be remedied afterwards, either on negatives or prints.

With respect to foliage, perhaps none give so poor a photographic result as the yew-tree; its sombre, black green and compact foliage coming out as a dark patch, void of detail in diffused light, even in bright sunshine, if included in a landscape, is mostly too dark for a pleasant effect. The white beam-tree and elder, on the contrary, photograph somewhat lighter than they appear. There is such an infinite variety in the form and effect of foliage that it is well worth a special study, and its value as foreground material cannot be overestimated.

Trees, irrespective of their own particular forms and colours, are most useful in breaking up horizontal lines in the landscape, often the only available material for the purpose; but, like most other things, there is a right and a wrong way of treating them. If trees in the middle distance come out black and heavy, by reason of the lighting or under-exposure, they generally spoil the picture; and when in the foreground, with too strong contrasts in light and shade, so that the lights are represented by white paper on the print, however good their forms may be, they are scarcely less so. A landscape photograph cannot be called good if the foliage is deficient in half-tones. The very rapid exposures now in vogue are very apt to produce these results, and are on this score to be deprecated. Sometimes it happens that the under-exposure of dark foliage is unavoidable. I may call attention to one particular subject that occurs to me, which almost invariably shows the bushes too dark. That is the general view of Box Hill, in Surrey—a favourite spot for photographers. Here the bushes come out as so many black spots on the hill-side; the brighter the day, the more decidedly spotty they appear. A slight haze might improve the effect, but in all the photographs I have seen of it the contrast is much too violent. These abrupt contrasts of colour frequently occur in chalk and limestone districts, where the outcrop is bare of vegetation, and the light reflected from the white surfaces in sunshine is so strong that the contrast between it and the green herbage tends to make a hard picture, requiring the utmost skill in exposure and development to overcome. The larger-leaved plants often supply most valuable forms for pictorial effect, notably the docks, digitalis, hemlock, and iris. The common thistle and nettle are not to be despised in this connexion, as they both, in form and colour, lend themselves to harmonious results. It need not be said that the foreground is generally the most important part of the picture, and on this account requires special attention. A good foreground is often the making of a picture, and an unsuitable or ill-chosen one its ruin. All the same, the distance must be by no means neglected because it takes a subsidiary place. No matter how beautiful the foreground may be, a peep of distance will wonderfully enhance its interest and pictorial value.

EDWARD DUNMORE.

DISRUPTION OF THE SILVER HALOID MOLECULE BY MECHANICAL FORCE.*

[Philosophical Magazine.]

EVERY FORM OF ENERGY DISRUPTS THE SILVER MOLECULE.

It is therefore true that every form of energy is not only capable of producing an invisible image (that is, of loosening the bonds which unite the atoms), but is also capable, if applied more strongly, of totally disrupting the molecule. This law, in a general form, was proved in previous papers with but a single exception, and that one exception is removed by the observations recorded in this paper.

As far as observation has gone, silver compounds are the only ones that exhibit this universal sensitiveness. Of other substances some are decomposed by heat, some by electricity or by chemical action, and a few by light.

It has now been shown, as I believe for the first time, that mechanical force is competent, without the aid of heat, to break up a molecule that owes its existence to an exothermic reaction.

It is important to distinguish between the two treatments here described. In the case of shearing-stress, force is expended in overcoming friction, and in so doing produces heat. It may be questioned, however, whether the very small amount of heat thus generated has anything to do with the reaction. The heat is not perceptible, it is momentary; and it has been elsewhere shown that though moist silver chloride can be broken up by heat, the action is slow even at a temperature of 100° C.

In the case of simple pressure, heat certainly plays no part. The material is small in quantity, is folded up in metal, is placed between large and heavy pieces of metal, and the pressure is applied gradually by means of a screw. Even supposing a slight increase of temperature, it could not exceed one or two degrees and would be momentary. As just remarked, heat does not produce an effect except at about 100° C., and after many hours.

The powerful affinity which exists between silver and the halogens is well known. That this affinity can be counteracted and annulled by simple pressure—that the halogen can in part be forced out of the molecule by mechanical means unaided by heat—is remarkable.

It need scarcely be said that this phenomenon has nothing in common with decompositions produced by mechanical force in substances such as silver or mercury fulminate, nitrogen chloride, and similar explosives. Such substances are all formed by endothermic reactions, and their decompositions are exothermic. Heat does not

* Concluded from page 490.

need to be supplied, but only what Berthelot has named a "*travail préliminaire*," an impulse to start the reaction. But silver haloids are formed by exothermic reactions; consequently their decompositions are endothermic, and require that the energy which was disengaged in their formation should be returned to effect their decomposition. The experiments described in this paper show that mechanical force may be made to supply this energy, and so play the part of light, electricity, or heat, without previous conversion into any other form of energy.

The thermochemical reactions of the silver haloids have been studied by Berthelot, and their reductions were found to be endothermic.* There can be no doubt, therefore, that an endothermic reaction can be brought about by simple pressure.

ADVANCED PHOTOGRAPHIC WORK FOR AMATEURS.

V.

One of the advantages in using rough-surface paper is undoubtedly the ease and certainty with which such can be printed and toned to any depth. Unlike bromide or platinotype (where, to a certain extent, exposure must dovetail with development), the rough-surface paper gives no trouble in this respect, being examined in the printing frames like ordinary albumenised paper. In toning, as a rule, a much weaker bath is used, and, by a judicious alteration of the ingredients composing the salting solution, quite a range of tones are obtainable, running from ordinary purple-black, through sepia-brown, to brown-black. It must, however, be borne in mind, when altering the various chlorides which form the salting solution, that their quantity in combination must be carefully considered, and the strength of the silver-sensitising solution made to suit such. For instance, one salting formula will work better with a sixty-grain sensitising solution than would be the case were the latter reduced to the strength of forty grains of silver to the ounce. It must also be borne in mind that some samples of paper will yield much finer results with one salting solution than that composed of some other chlorides, so that, once a good formula has been hit upon for each particular paper by experimenting, it is well to keep to it. In this alone an enthusiastic worker has much to engage his thought, and there are a great many papers in commerce quite suitable for use, even the common web paper, which can be bought in rolls of great lengths, and various widths, and varying tints. I have obtained excellent results from such, the price of this class of material being very much cheaper than that of Whatman's drawing-paper.

In toning, quite a range of colour is obtainable, provided suitable negatives are being printed from. In this class of work it is imperative that such have plenty of pluck and vigour. When this is the case, results will be obtained that will surpass any other class of printing material that I know of; therefore workers should aim at the production of bold, vigorous negatives. The miserable flat productions usually seen as the result of using very rapid plates are quite unsuitable for this class of paper, and, indeed, for both platinotype and bromide work also.

With suitable negatives, a good formula for purple-black tones is—

Water	120 ounces.
Acetate soda	300 grains.
Phosphate of soda	160 „
Tube gold	15 „

The printing must be carried further than would appear necessary when using ordinary albumenised paper.

For sepia or warm brown tones the printing is not carried so far, and a weak borax bath used.

For brownish black tones, a bicarbonate of soda bath is used, freshly prepared.

The treatment of the prints, both before and after toning, being as nearly as possible the same as for ordinary albumenised paper, the fixing bath I prepare as follows:—A gallon or two of a saturated solution of hypo is always kept in stock, and when going to fix my prints—say, in winter—I take one volume of saturated solution of hypo to four volumes of warm water; in summer, cold water may be sed.

The mounting of these prints is a pleasure, there being almost an entire absence of the cockling so troublesome at times with other papers. A good flour paste, well boiled, with a few drops of oil of cloves added by stirring well after it is boiled, and, when cold, pressed through coarse muslin, makes, for these thick papers, the best mountant it is possible to use.

To those workers who have never done anything in the way of preparing their own printing paper I can promise a genuine delight in their undertaking the salting and silvering of a sheet or two after the manner I have described. It is quite a cleanly and easily executed operation, and even ladies need not for a moment hesitate to try their hand. Should the silver solution, by coming in contact with the tips of the fingers whilst being applied to the surface of the paper, cause stains, such are easily removed with the aid of a little pumice-stone; and in very aggravated cases, such as splashes through accidentally spilling some of the silvering solution, an application of some powdered chloride of lime, rubbed by means of a damp flannel over the hands, will remove all traces of the silver stain as if by magic, and any smell of the lime is easily dispelled by using the juice of a lemon on the hands afterwards.

It is not, however, in the preparation of rough-surface printing paper alone that amateurs find scope for interesting occupation of more than ordinary pleasure, and once they have tasted of the delight it will be strange indeed if they do not long to fly at somewhat higher game, such as the salting and sensitising of cloth and other fabrics.

Therefore, should any one feel disposed to try their hand at printing on fabrics as a start, they need not be deterred by any thought about the difficulty of the operation, for they can from the Platinotype Company get ready-prepared sensitised material, such as nainsook, sent them on application, the working of which is by no means difficult provided suitable negatives be employed, for in reality it all lies in this. Supposing, therefore, it be desired to make a lady friend some little present in the way of a useful article, be it a marriage gift, or a slight donation to a bazaar for some worthy object, what is more suitable than, say, a dozen or two round or oval-shaped d'oyleys? and these, when carefully printed in platinotype, and handed to a member of the fair sex, to adorn, by means of an edging of lace or crochet work, ferms a gift that is always highly prized and quite permanent. I have seen a set of two dozen mats for finger glasses adorning a dining-table that gave no end of pleasure, and which were highly prized indeed, and yet the production of such was a matter of no great difficulty; indeed, any one possessed of suitable negatives could, with the greatest of ease, produce such.

In the selection of suitable subjects for such adornments, there is alone room for the exercise of much taste and thought, and, as a rule, it will be found that copies from photographs, portraits, engravings, pictures, &c., instead of from negatives taken direct, will yield quite as charming results, for, as a rule, a negative that will print well on some classes of albumenised paper would be too soft for such work; therefore I have found it best to prepare special negatives for this class of printing. Let us just take a case in point. Say it is desired to present to a lady a mat, or some other little souvenir as a birthday present. This may take the form of presenting a copy of a well-liked photograph, say, a portrait, and having obtained an ordinary print of this, which, for example sake, we will imagine is a vignetted head and bust of, say, half-inch size, the first step to take is to produce a somewhat enlarged negative from same, say, almost double the size. This is best done by placing the print in a printing frame carrying a sheet of patent plate glass. The print is then pressed close up to the glass by means of the back and springs of the printing frame. The latter is then placed on edge on the copying board, and with the aid of a *slow* bromide plate a negative is produced which is strong in contrast. This is easily accomplished when the exposure is such as to work in harmony with a developer that is strong in pyro and bromide. These points must be carefully attended to, and, of course, it is an easy matter by arranging the distance of lens and camera from the picture to make the image somewhat larger than the original; by this means there will be no grain of the paper visible, but in this class of work such is really not a matter of much importance. The great aim is to select suitable subjects and get good plucky negatives of such. I have found Mawson's lantern plates admirably adapted for this class of copying; so also are Edwards's *slow* isochromatic plates especially useful in all cases where black-and-white or coloured objects have to be copied. A fast plate yielding a thin image will certainly end in failure. However, once a good vigorous negative is obtained, the whole thing is reduced to an operation of the greatest ease. A supply of nainsook or other fabric is obtained from the Platinotype Company, and printed and developed with the necessary care; the picture is then cut into any desired shape by means of, say, a plate or saucer, as would be the case when rounds are desired, leaving a slight margin whereby the photograph is tacked by means of needle and cotton to some other suitable fabric as a flexible support. These

* *Mécanique Chimique*, vol. ii. p. 411. The reduction of silver chloride to metal involves an absorption of cal. 29·4. That to hemichloride has not been measured, but is, according to Berthelot, also endothermic. See also Ditte, *Les Métaux*, i. pp. 232, 233.

thread markings are then overlapped, when you get your lady friend to stitch on the lace or crochet-work as the edging.

Admirably adapted for such are yachting subjects, and, when these are vignetted, their suitability is enhanced; large originals can be easily reduced, and negatives made specially for this class of printing by exactly the same method, only in this case the camera and lens are moved further away when copying.

It is not only platinotype, however, that may be employed for this class of work; very delightful pictures can be obtained by many of the other methods of printing, especially the blue process.

T. N. ARMSTRONG.

"INDIVIDUALITY IN PHOTOGRAPHY"—A REPLY TO MR. H. P. ROBINSON.

I TRUST you will be kind enough to grant me space to reply to the remarks (so far as they relate to myself) contained in the paper on "Individuality in Photography," by Mr. H. P. Robinson, and read for him at the Photographic Convention.

When one is merely ridiculed in place of being argued with it becomes somewhat difficult to defend oneself. To condescend to the same tactics and fight with the same weapons is generally an easy enough way out of the difficulty (that is, if one should be unscrupulous enough) and it would be particularly easy in this case.

As ridicule, however, is mere impertinence in any serious discussion, I do not intend to avail myself of its questionable aid. I think I am not mistaken in discovering throughout the whole of Mr. Robinson's paper an under-tone of self-assumed infallibility. Indeed, the very fact that Mr. H. P. Robinson expects the members of the Convention to believe that my ideas are preposterous without any argument at all, but merely on the strength of his word, pre-supposes this.

Let it be granted that Mr. Robinson is the author of photographic work that has not been excelled, he surely cannot presume on this to set up as an authority in philosophy. The question of whether or no photography is to be reckoned as one of the fine arts is one in the settlement of which neither artists nor photographers can be allowed to have any special authority. It is not necessary to be either an artist or a photographer to discuss the matter, and it might be argued that, both being interested parties, each is only entitled to state his own side of the question, the decision resting with those who have no interest one way or other in the matter.

Mr. Robinson is no authority whatever on the question of whether or no photography is to be reckoned as one of the fine arts, or, if he is, the evidence of it has heretofore, like all honest merit, ever loved the shade. Disposing of the rest of Mr. H. P. Robinson's paper (beyond what relates to myself) by candidly admitting that I do not in the very least know what he is driving at, and confessing to a perfect impatience of his primitive logic, I pass on to his remarks upon my own paper. As the argument in my paper is a cumulative one, I have a perfect right to object to Mr. H. P. Robinson disintegrating it, and calling in question separate fragments, but I waive this point and argue the question. He ridicules and objects to the following statement: "The picture painted by the artist is a transcript of his own emotions, but a photograph is not a reflex of human emotions at all, unless indeed accidentally so, but is a direct reproduction of nature, and only through science the offspring of man." Mr. Robinson adds, "We must be grateful to the writer for allowing us the accident."

From this remark I deduce the origin of Mr. Robinson's confusion. If Mr. Robinson had had an adequate knowledge of what I take to be his mother tongue, he would have known that "accident" and "chance" are not always one and the same thing. For Mr. Robinson's behoof, and in no spirit of retaliation, I must point out to Mr. Robinson that all *unessential* qualities or properties come under the term "accident." If it is not too fine a point for Mr. Robinson to see, let me state that fidelity to an original (even approximate) is no *essential* concomitant of the processes which culminate in a photograph. It is not surely with the *intention* of producing a likeness of anything that any one of the processes takes place, and a likeness is brought about it is not that photography implies anything more than the action of light upon substances capable of being acted on. This is the only *essential* part of photography, likeness making is *accidental*. If a photograph turns out to be a transcript of any man's emotions, no matter how much he has done to bring it about, it is there what it is, the result of natural laws working entirely independent of his emotions, and is therefore strictly *accidental*.

Mr. Robinson must be very dense if he cannot see that this is an entirely different thing from a picture painted by an artist. A photograph *happens*, we shall say, to be what a man sees; a painted picture *is* what a man sees. Fidelity or likeness to an original is an *accident* in photography; in a painted picture, on the other hand, it is *inherent* and *essential*—part of the creation. Do not mistake me. The picture of the artist may not be true to nature, as a photograph is; but herein lies its superiority. It is true to the artist's conception, which is nature plus genius, and which is just the difference between *choosing* a picture and *making* one.

In reading over Mr. Robinson's paper, one is strongly tempted to discover the absurdities as they come, line after line; but as I have only my own affair to settle with him, I take his next quotation. "The latest of the many attempts to define art is a very remarkable one," says Mr. Robinson. It is said to be "the apparent disproportion between the means employed and the end obtained."

If Mr. Robinson has read my paper carefully (which I certainly doubt), he will find that this is the definition of *art*, as distinguished from *fine art*, and must be sufficiently comprehensive to include every kind of art whatever. It is waste of time to try to determine what *fine* art is until the broader and more comprehensive term of art itself is determined. Mr. Robinson thinks that "individuality" is art. Individuality is an *accident* of art (to come back to the stumbling block of accident), but is not art itself.

If *individuality* be art, there cannot be much or little of it; whereas everybody recognises *degrees* of art. Let us take a case in point. I am shown a painting, and in it see much that suggests the hand of Turner; but there is a doubt. Again, I see another painting, and am more convinced than before that this is by Turner. A third picture is shown me, and this time I have no doubt whatever. Am I to understand that, as there was more and more of the Turner *individuality* in each successive picture, that therefore there was more and more of *art*? If my idea of art is to make the practical photographer smile, surely this will make the whole common-sense world smile. It surely does not require a genius to see that a man's individuality at one period of his life is not the individuality of another, and that, in some cases, the individuality grows at the *cost* of art, and mannerism is the result.

Not only is *individuality* not art, it is opposed to it, as a moment's consideration will show. According to Mr. Robinson, the more of the man you have in his work, the more of art. I think most of us have seen many instances where the *less* of a man we had, the more art. Apply the same test to my definition, throw overboard the individuality test of Mr. H. P. Robinson, and let us have in again the three paintings. I take the first, and note that, to get a certain effect, much work has been expended; the artist is a beginner. I take the second, and find that the same effect has been produced with half the labour; the *art* is doubled. And I take the third painting, and find that with still less labour the very same effect has been produced; here, again, I say we have still greater art. Now, a moment's consideration will show that, the end in each case being the same, the greater merit lay in the reduction of the labour to produce it; in other words, the apparent disproportion between the end obtained and the means used.

It has been well said that the highest art is to conceal art. If Mr. Robinson's idea be the correct one, and individuality be the prime factor in art, the very reverse would be the case; for *individuality* is not to conceal, but to reveal. Art (not works of art, nor works of fine art, but art in essence) is the faculty of producing the greatest effect by the simplest means; in other words, "the apparent disproportion between the means employed and the end obtained." Many people confound art with æsthetics. Art has no special connexion with beauty or taste, or, for that matter of it, with either soul or conscience, as Mr. H. P. Robinson thinks. *Fine art*, an entirely different subject, is certainly most intimately connected with the emotions, although Mr. H. P. Robinson does not seem to appreciate any distinction whatever between art and fine art, but classes in his definition of art such widely diverging arts as pugilism and painting, evidence surely of an unthinking mind.

A somewhat long quotation from my paper on the relation of photography to art (not fine art) requires a few words. I deny that art, to any great extent, enters into the photographic processes which go to produce a picture. Mr. Robinson affirms that it does. We may narrow the discussion on this point to one of exposure and development, as a very few have to do with the plate in its manufacture. And, first, as to its exposure. The photographer has in his exposure to consider three things. First, "composition or effect;" second, the allowances which he must make for the shortcomings of the photographic process; and, thirdly, the duration of exposure.

As to the first, I deny that it is *art*, and affirm that it is intuition. Artists, like poets, are born, not made.

It is in the selection of his subjects and his treatment of them that the photographer can show the stuff he is made of, and I have never denied this. So far as the selection of his subject and the treatment of it is concerned, he is on a par with the artist; but the picture is not a work of fine art for all that. It is, if I may be allowed to coin an expression, "a work of fine intuition." It is a measure of a man's emotional character, that must be admitted, but a measure made manifest chiefly through *science*, not *art*.

Under the second head the photographer must by *art* determine the alteration in his composition brought about by the shortcomings of photography. I allow art here; it is not a matter of intuition. He must learn by experience what allowances he has to make on his compositions for the shortcomings of photography and *art* is necessary to make up for them. Either he employs legitimate *photographic* art, as by modifying exposure, or development, or both, or he may employ what may be termed non-photographic art, such as retonching the negative. This latter method, not being a photographic process, requires no consideration at our hands, and, of course, it cannot affect the question of whether or no photography is one of the fine arts. To this extent, then, I admit *art*.

With regard to the *duration* of exposure, this is generally a matter of art, but need not always be. We may have no certain means now of conveniently determining the exact period of exposure, but undoubtedly it is a calculable problem, the data being already to hand.

With regard to development, every day seems to make it more certain that it is just what I contended—a chemical experiment, scientifically interesting, but devoid of art. Having, at considerable length, discussed the question of art, it is, in my estimation, not a difficult thing to determine the meaning of the expression "fine arts."

By common consent, the *fine arts* are those *arts* dedicated to the expression of the emotions. It may be the expression of beauty or ugliness, joy or sorrow, but the expression must be through *art* (the prerogative of intelligent creatures), and not through science.

I have only this more to say to Mr. Robinson. I am not a scientist, but (if anything) a practical photographer, actively and uninterruptedly engaged in the pleasant pastime now for more than twenty years.

J. K. Tulloch, M.B.

THE PREVENTION OF HALATION.

The subject of halation, though an ever-present one, does not occupy so much space in the journals as one would be inclined to expect. No doubt workers have been able to overcome much of the trouble incidental to the exposure of gelatine plates on *interiors;* also, undoubtedly, our studio and landscape examples have reached a very high point of excellence—this, it must be remembered, with the means at our present disposal. The introduction of a new plate, designed specially for the prevention of halation, would go to prove this bugbear to be lively as ever, while the following remark in a semi-editorial *critique* of a new lens of wide angle, with more than the ordinary wide aperture, to the effect that "this means shorter exposure (interiors), and consequently less danger of halation," appears to me to denote a doubtful knowledge of this trouble, not so much as to its *cause* but its *prevention*. The cause has been demonstrated frequently and fully. It is only by experience we discover a preventive.

In order to photograph interiors with a fair amount of certainty, (1) the light must be suitable, *no* sunlight preferably; dull, foggy even, provided the interior be free from fog; or rainy weather. (2) A good brand of dry plate; a plate easily worked outside, giving density, one which will bear forcing—a plate, in short, which contains a fairly thick stratum of emulsion. (3) *Backed* plates; the backing brown, dense yellow, or black paper, blacking, Japan black, or, what I invariably use, equal parts of collodion and matt varnish in which has been dissolved a good proportion of rose aniline. This liquid is poured on and off the *back* of the plate, previously cleaned; it dries quickly, with a dead matt surface, and is easily removed prior to development. (4) Plenty of exposure; where one works by tables, always give at least three times the exposure prescribed.

It is quite certain that many interiors, even those most prone to give halation, may be successfully photographed every time with ordinary plates well backed, *provided the light be right*. One interior I have in mind is a case in point. A large bank office, some thirty yards square, windows all along the front, facing the street; at the back light has access only through a conservatory, occupying one-third of the space. The windows are ordinary plate, marble columns, beautifully ornate and coloured ceiling, and fine oak carvings. The morning chosen for this order turned out even better than was hoped for; a dull, dreary morning, raining incessantly, barely enough light to focus by. The conservatory, where halation was most to be feared, was illuminated by what appeared to be practically yellow light, from the atmospheric conditions prevailing outside; and this was a bit of good fortune not anticipated. An exposure of four hours was given—ten o'clock till after dinner; and the resulting negative was a complete success, no trace whatever of halation. It must be obvious this portion of the interior would have received considerably more exposure than absolutely necessary; I am inclined to think that an alternating negative and positive process goes on in such cases. Other subjects to be successfully photographed under similar conditions of atmosphere are showrooms, structures lighted from the top and sides, workshops, conservatories, winter gardens, and the like.

A troublesome interior was the private chapel of a well-known Bishop; the place was incomplete at the time, the windows being temporarily glazed with ground glass; the east window commenced immediately above the reredos, the latter, a beautiful gilded and coloured work of art; following the rule of a dull day and prolonged exposure, a negative was secured which, with regard to the windows, was all right, but the altar-screen had suffered, and, in order to secure a satisfactory result, two negatives were taken on a subsequent occasion—one in the usual way, the second from exactly the same standpoint, but, by carrying forward a tunnel-shaped shade from the camera front, particularly at the top, much more detail was visible, and, in fact, the window could be blocked or screened out altogether. double printing was necessary, but I don't think this subject could have been secured any other way.

Some church interiors are very badly lighted. Stained-glass windows here and there; occasionally, to throw a little light into the roof, some rabbit-hutch-like windows will have been inserted up aloft. The place will be full of harsh contrasts. What is the best remedy? Simply prolonged exposures. One need not be deterred, even though sunlight be streaming through the windows; a short exposure here will be fatal—give plenty, and the result will be pleasing.

We must all welcome any improvement in dry-plate making, though many of us are inclined to ask, What is the matter with the old ones? Given a little more "body," they are as good as need be. Plates were coated more liberally before the advent of high-class machinery; the makers are "a bit too canny" with their emulsions nowadays, and there can be no doubt whatever that the film must be fairly thick to be at its best. Apart from this, plates have arrived at a very high standard, and in practised hands are capable of the most satisfactory work. In conclusion, I am pretty certain that the great majority of failures through halation are simply failures on account of (considerable) *under*-exposure.

J. Pike.

HINTS ON MOUNTING PHOTOGRAPHS.

[Anthony's Bulletin.]

In this article we have endeavoured to give a few of the most important points of manipulation in connection with mounting photographs, deeming that they might prove useful to some of the younger of our photographic brethren.

From among the various pastes and mounting preparations it is necessary to select the one best suited to our needs. For prints having a decided and seemingly irremediable tendency to curl when moistened, it is advisable to use a paste of considerable tenacity, as otherwise the tedious and unpleasant operation of "licking" down the corners and edges will have to be resorted to.

There are two golden rules in selecting a mountant that should always be remembered. First, to have the mounting medium fresh, and not in a state of partial decomposition. Want of care in this direction has materially hastened the fading of many a print. And, second, to employ such a one as will not readily take up moisture from the atmosphere after being once used. Glue and gelatine are both somewhat open to this objection, but the employment of a very thin layer partially does away with the objection in these two cases, while, for some operations, gelatine itself is well-nigh indispensable. Thus we prove our second golden rule by quoting immediately after it the exception: the first one should admit of no exception or deviation.

To prepare the glue, break it up into small pieces and half fill the glue pot with it, which should be placed in a second pot filled with boiling water. Add a little cold water to the pot containing the glue, and place both on the fire. In a short time the glue will be melted; stir it up with a stick, when it should be of a thin watery consistence and just tacky when put between the finger and thumb. If too thick, add a little more water; if too thin, a little more glue. This mountant must be used hot, and it is best to keep it immersed in its jacket of boiling water during the operation of mounting.

To make the gelatine paste, soak two ounces of soft gelatine in cold water, and then pour on sufficient boiling water to make a rather

thick solution. When solution is complete, strain through muslin nto any convenient receptacle. When using, heat by standing the vessel containing it in hot water for a short time.

Starch paste we believe to be ordinarily the best of mountants, and it is best prepared fresh as needed. A teaspoonful of the starch should be thoroughly wetted and stirred in a small saucepan with cold water, any lumps which may form being broken up until the mass resembles a cream; this is then poured into a half pint of boiling water, stirring constantly while adding. Allow to cool and strain through muslin. If it is desired to keep this for any length of time, a pinch of salicylic acid should be added to the boiling water and stirred until dissolved before adding the starch.

To prepare the prints for mounting it is necessary to first trim them. For this it is convenient to have a glass form of the desired size. These can be readily obtained of the dealers and insure square corners and uniformity among your trimmed prints. A cheap knife such as is used in the kitchen for paring potatoes, and a rough sandstone are necessary adjuncts.

Lay the print down on a sheet of heavy glass, place over it the glass form, and trim with the before-mentioned potato knife; the rough sandstone readily gives a sharp, somewhat serrated edge, admirably adapted for this purpose, and a quick movement of the knife produces a clean, sharp cut with no ragged edges. Care should be taken to hold the glass form firmly upon the paper while trimming as an additional precaution against tearing.

The prints should next be thrown into water, and thoroughly soaked, and then laid face down—one on top of the other—on a sheet of glass; much of the superfluous moisture can be removed by pressing down on the pile with the hand, and allowing the water thus squeezed out to run off by tilting up the glass.

If this is not sufficient, lay a clean towel over the back of the print just before applying the paste, and smooth it down; this will leave the surface only slightly damp, and in excellent condition to receive the paste, which should be applied with a wide flat brush, in a thin, even coating, taking care that no lumps are left on the print before applying it to the mount, and that the edges and corners are well covered. In this way no paste is distributed on the face of the print, where it otherwise has an unpleasant habit of getting, and the whole operation can easily be conducted without any of the inevitable "mess" which so often unnecessarily follows many of our photographic operations.

Having applied the paste, insert the point of the knife under one corner of the print, gently raise it, and take hold of the print by the thumb and forefinger of each hand by the diagonally opposite corners. Care should be taken to grasp the print at some distance from the edges, to avoid removing the paste from them with the fingers, and having them curl up when dry. Touching the paste brush lightly with those fingers coming in contact with the pasted side of the print, is also a good precaution to take for the same reason. In taking hold of the print, the thumb should be inserted under the picture side, when it is very easy to reverse its position, and bring it to the proper one for applying it to the mount.

By a little practice you can hold the print in this way so as to almost let the two free corners touch the mount, and the proper placing can in this way be readily judged without the use of a mounting board.

In lowering the print upon the mount, let the diagonal passing through the two free corners first touch, and then gently and gradually lower the other two corners. The print will now lie flat and even upon the mount without any air bubbles making their appearance. It is next to be squeegeed down, and any paste exuding from the corners to be at once removed with a clean towel.

In the absence of a squeegee, a towel laid upon the face of the print and carefully rubbed down with the fingers from the centre to the edges of the print will answer every purpose.

When dry the edges should be examined, and if they show any sign of curling, an ivory paper cutter should be carefully inserted and the edges of the picture slightly detached from the mount. In the opening thus formed a feather will be found very convenient to apply the paste with.

In some extreme cases it will be found necessary to dry the prints between towels under pressure of a pile of books or a letter-press, to prevent the curling up of the edges.

Too hard a pressure on the squeegee will sometimes squeeze out too much of the paste and cause the above-mentioned difficulty.

Blotters are not to be recommended for drying prints, as they are liable to leave "fluffs" over the surface, which, when dry, are difficult to remove.

Sometimes the prints are mounted face side down upon glass, and the finished picture viewed through the glass. In the case of bromide and chloride prints it is only necessary to squeegee the print, face downwards, upon a perfectly clean sheet of glass and allow it to dry. With albumen prints it is necessary to give the glass and print a coating of the warm gelatine solution mentioned in the first portion of this article. Lay it on one side to set, and subsequently clean the glass with a clean sponge dipped in hot water, but do not touch the print itself.

A picture of this kind can be backed with rough drawing-paper, which will appear as a mat, and the whole may be bound to another piece of glass, similar to the method employed in mounting lantern slides. This is an excellent way of using up spoilt negatives, and a most effective and permanent method of mounting.

Select your mounts with special reference to the subject, and give them plenty of margin, as it will greatly enhance the beauty of your picture. How many of us have seen an otherwise excellent and attractive print marred, if not totally ruined, by an inappropriate setting?

NOTES ON STAR PHOTOGRAPHY.

[Science.]

An announcement has recently appeared to the effect that the French astronomers have begun to doubt the value of negatives of stellar bodies taken on orthochromatic plates, because the stellar discs are surrounded by a strong aureola, due to the aberration of the red rays of the objective. For this reason the permanent committee on the chart of the heavens has decided to exclude orthochromatic plates for such work.

I presume every one finds some satisfaction in saying, "I told you so." The announcement leads me to publish now an article on this subject which was written in Japan between four and five years ago. It was perfectly clear to me, at that time, that colour-sensitive plates were being used in astronomical work when the very opposite kind of plates would have been much better for the purpose. Instead of extending the sensitiveness, it should have been restricted as much as possible. My article was not published because I deemed the facts too obvious to require discussion. But, since M. Léon Vidal, Editor of *Le Moniteur de la Photographie*, has taken, as I believe, an erroneous view of the matter in opposition to the practical results of the astronomers, I have looked up my old MS., and publish it herewith without change.

I would add, that the opinion then expressed as regards the future of collodion plates for all scientific work has been greatly strengthened by the results of later investigations.

The article referred to is as follows:—

The so-called isochromatic, or orthochromatic, sensitive plates have been recommended for use in astronomical photography, in order to obtain impressions of red or yellow stars along with those having more blue and violet light in their radiations. Spectroscopic observations have shown that the light of different stars differs very much in the proportion of highly refrangible rays, and this difference must be of great influence in determining their photographic action. The ordinary sensitive gelatine plates possess a maximum of sensitiveness near the Fraunhofer line H; but some action can be traced into the yellow, as the result of very long exposure, or even still further. For ordinary purposes, however, we may consider that the action does not pass the blue, particularly when photographing bright sources of light, such as the stars, because the more refrangible rays are so very much more powerful in their effect upon the plate that they exert their full action before the others can make a visible impression. To extend the time beyond that point would result in a reversal of the effect sought for, a change in the character of the negative, and serious irradiation or spreading of the light around the image, resulting in impaired definition. With ordinary sensitive plates, therefore, the images we photograph are images made with blue, violet, and ultra-violet rays, covering, indeed, a considerable range in the spectrum, but excluding a large and important portion of it.

The differences in the character of star radiations are so considerable that the blue is sometimes very strong and brilliant, even exceeding that of the sun relatively to the other parts of the spectrum, as we find it in *a* Lyræ and in Sirius; while in other stars the temperature is so low that there is scarcely any blue, and line-absorption gives place to flutings, or even to the bright lines of incandescence from comets and nebulæ. It is obvious, therefore, that one star not only differs from another in glory, as seen by the eye, but the photographic plate, which takes no account of any colours beyond its limited range of sensitiveness, tends to exaggerate the difference, and give utterly false evidence of relative brightness. For a red star may appear very bright to the eye, while its image on the plate would be very faint, or perhaps scarcely discernible.

With orthochromatic plates the result will be different, provided the telescope itself is not at fault. We will assume for the moment that the

telescope is so constructed that the "chemical" and visual foci exactly coincide, and that the plates are equally sensitive to all the colours of the spectrum. Then the negative will show exactly what is seen by the eye, and these are the only conditions under which such a result can be perfectly attained.

Doubtless such perfectly corrected telescopes, or perhaps I should say such as are so corrected within the limits of the optician's skill, are rarely available, and a very usual plan is to make certain corrections for ordinary telescopes to adapt them to photographic work. The effect of these corrections now deserves consideration.

The difference between the so-called "chemical" focus and the visual focus of a telescope may be little, or it may be half an inch. In either case the photographed image will be decidedly out of focus if allowance for this difference be not very carefully made. The usual means of doing this is to change the position of the plate-holder, and find the place of the sharpest definition by trials. By properly arranging the ground glass and the plate-holder, the plate will always be in focus for the actinic rays when the image appears sharp on the ground glass.

Having accomplished this result, we have succeeded in doing precisely what we do not wish to do, viz., instead of arranging the instrument to photograph what the eye can see, by means of the extended and uniform sensitiveness of an orthochromatic plate, we have arranged it to define only with blue or violet rays, and have restricted its range to stars that are specially characterised by highly refrangible radiations, effectually cutting off the red and yellow stars, and rendering the use of orthochromatic plates not only useless but positively objectionable.

As regards the red and yellow stars, the greater portion of their light will be brought to a focus at the point of distinct vision, not on the sensitive plate, and, the feeble radiations of higher refrangibility being too weak to act strongly on the plate, such stars will be but faintly shown in the negative. The rays not focussed on the plate will tend to blur the images, and this effect will be more pronounced and objectionable in proportion as the range of sensitiveness of the plate to the different parts of the spectrum is increased. For this reason the most perfect pictures would be produced, under the conditions described, by using plates sensitive only to the particular rays that form the image on the plate, or else by cutting off the other rays by a screen, thus working with monochromatic light.

It is possible that there may be some object in photographing stars with the different colours of the spectrum separately, in which case orthochromatic plates can be so prepared that they will select the particular light required, and such observations may be made with ordinary telescopes, correcting them for each set of rays in turn, in the manner described. But, if I correctly understand the purpose of photographic star-maps, they are intended not only to represent the distribution of stars and their relative positions, but also to show their respective brightness, or, as we usually call it, magnitudes. Now, magnitude measured by brightness is not the same as the photographic action of the stars upon a plate of restricted spectrum sensitiveness, such as all ordinary sensitive plates, and this, although a self-evident proposition, has not received in practice the attention it deserves. On the other hand, orthochromatic plates will give perfectly truthful representations of the starry heavens when used with perfectly corrected telescopes, as already explained, and that they will only do so under such conditions is, I believe, obvious.

If it is possible to make plates of uniform sensitiveness as regards tests in the sensitometer, and also as regards all the rays of the visible spectrum, and if such plates can be produced regularly in large quantities, we may consider the problem of photographing the stars to be satisfactorily solved. But much yet remains to be done before a plate that can be regarded as standard can be adopted. The composition of the emulsion, the manner of rendering it sensitive, the means of testing the plates, including the standard of light to be used in the process, and the keeping qualities of the plates, must all be thoroughly investigated before it will be safe to adopt a standard plate for universal use. Nevertheless, we are in a position now to begin practical work, and the results will be of permanent value if we act upon the proposition that with orthochromatic plates there is no distinction of chemical and visual rays, and that such plates can only be advantageously employed when all the rays from red to ultra-violet are brought to a focus in a single plane.

I do not venture upon any speculations as to the probably best method of preparing colour-sensitive plates for astronomical work, for the reason that new methods are constantly being tried. I will say, however, that I deem it not at all improbable that collodion will be found superior to gelatine as a vehicle for the emulsion, and, although the gelatine plates are at present more rapid than collodion emulsion plates, there is no obvious reason for this, further that than we do not yet know how to make extremely rapid plates with collodion. But there are some objections to gelatine, and none to collodion. Gelatine swells in water, particularly in warm climates, and, although this defect can be to some extent controlled, it is really at times a serious trouble, which no "tropical" plates can entirely overcome without a sacrifice of other good qualities.

The great point in favour of collodion is that it seems to lend itself peculiarly well to the production of colour-sensitive plates, and this, coupled with the uniformity of the material that can, by proper means, be secured, and the clearness with which it works, leads me to anticipate that it will eventually rival gelatine for fine, delicate work, and I believe it will come to be highly favoured in astronomical work and spectrographic work.

ROMYN HITCHCOCK.

LANDSCAPE PHOTOGRAPHY WITH ORTHOCHROMATIC FILMS.

[American Amateur Photographer.]

DURING the past few years, in a rather extended experience abroad, I have made extensive use of orthochromatised emulsions coated on celluloid films; a few notes, therefore, concerning the practical details connected with their use may be of value. It may be stated in advance that the deductions given in this paper are based upon some eleven hundred exposures made in Southern Germany, Switzerland, and Italy, during the summer of 1890, and in Norway during the summer of 1891. These were made under the most varying conditions of light, and embraced every variety of landscape usually attempted by the average photographer. No "snap-work" or instantaneous exposures were made on orthochromatic films.

ORTHOCHROMATISM.

It is hardly necessary at this late day for me to go into any lengthy dissertation upon the subject of othochromatism, or to attempt to explain at length what is meant by the term, for the value of plates prepared in this manner is now well recognised, and the whole theory has been repeatedly and in detail described at different times in numerous photographic publications. Suffice it to say that a plate or film coated with an orthochromatised emulsion displays certain peculiar characteristics in regard to light and to the various component coloured rays of the spectrum. An ordinary photographic emulsion is always actively affected by the blue rays of the spectrum, while it is almost equally indifferent and insensitive to the action of the yellow, orange, red, and green rays. The consequence is, that in photographing a landscape blue appears as white, while the greens, reds, and yellows, although to the eye markedly different in colour-tone or gradation, produce practically the same effect upon the photographic emulsion, and are all represented in the finished positive as blacks of about the same colour gradation. The orthochromatic emulsion, on the contrary, while less sensitive to blue as the plain emulsion, is more sensitive to the yellows, greens, and reds, and in much more correct relation to their colour intensity. Colour values are, therefore, more correctly rendered, and this rendition is made even more perfect by the interposition of a yellow screen between, before, or behind the lens combination used. This acts as a light strainer or filter, so to speak, filtering out and holding back the blue and violet rays of the spectrum, and allowing the yellows, greens, and reds, in which the luminous vibrations are slower and of less intensity, an opportunity to act fully upon the emulsion. It may also be noted that with an ordinary emulsion the colours blue and white affect it equally, so that, for example, in photographing a lady dressed in blue and white, the finished positive would represent her as in white entirely. In landscape photography this is a great drawback, for when, for instance, making an exposure upon a snow-capped mountain standing out against a blue sky, the two act so equally upon the emulsion that in the positive it is often almost impossible to note where the line of demarcation exists between the two, the whole being rendered as an unmeaning mass of white, instead of showing the brilliant and clear contrast between the two that there is in nature. With an orthochromatised emulsion, however, the result is quite different—blue appears darker than white, as, in fact, it does naturally to the eye; and this effect is brought out even more prominently by the employment of the yellow colour-screen. This holds back the action of the blue rays, and also gives the darker tints in the nearer foreground the opportunity to properly impress the plate.

WHY ORTHOCHROMATIC PLATES ARE USEFUL.

Now, with the above points clearly understood, we can appreciate why the orthochromatic plate or film should be so useful in landscape photography.

First. The different shades of green in grass and foliage, ranging often from a light yellowish green to a shade so dark as to be almost

black, all have their proper effect upon the plate, and the resulting positive shows them with their proper colour values as expressed in black and white. There is hence much brilliancy and gradation of tone obtained.

Second. As the orthochromatic emulsion differentiates between blue and white, delicate cloud effects are obtained which would be utterly lost with an ordinary emulsion. I have often been asked how I obtained the realistic cloud effects which I have shown in some of my Swiss photographs and lantern slides, and, in fact, have sometimes been asked if they were not "printed in;" but, thanks to orthochromatic films, no such procedure has been necessary, for the clouds are "right there" in the original negative.

Third. In large and extended landscapes involving considerable distances, an orthochromatic emulsion used with a colour screen is almost an absolute necessity. Otherwise the blue rays from the more distant portions of the landscape would utterly "burn out" their particular part of the plate before the foreground had been fully exposed. All sorts of devices have been suggested to overcome this difficulty—sky shades, shutters exposing from the bottom upward, &c., &c., but none have met with sufficient success to warrant their adoption. With a good orthochromatic plate of moderate rapidity, or an orthochromatic celluloid film, which is even better, owing to absence of halation, and a yellow colour screen of moderate depth of colour, all these difficulties are avoided, and a satisfactory result can nearly always be obtained. I have grown to depend upon this method of procedure so much that I think nothing of attempting a landscape where a distance of some forty of fifty miles is involved, and can usually obtain in my picture as much, if not more, than I can see with my eye. I can obtain, too, a picture with harmonious gradation, a fully exposed and satisfactory foreground, full of light and shade and plenty of detail, while the middle distance and extreme distance show both detail, atmospheric effect, and good tone gradation. Furthermore, if there are clouds, I am *sure* to get them, and, excepting there be sufficient wind to cause their outlines to be blurred by movement during a long exposure, the result leaves nothing to be desired. I have one negative, a view taken from the top of the Furca l'ass, in Switzerland, in which, while the foreground is well exposed and satisfactory, the Alps of the Monte Rosa and Mont Blanc groups are clearly visible, although nearly a hundred miles distant. It would be wholly impossible to obtain such a result with an ordinary emulsion.

Fourth. Effects of sky and water, reflections of clouds in the water, snow-capped peaks and glaciers standing out against a blue sky. Autumn changes of foliage, &c., &c., with an orthochromatic emulsion, are rendered with a fidelity impossible to obtain with the ordinary plate.

Orthochromatic Films.

I have thus far used the term plate in a general sense, meaning either glass or celluloid. While there is no doubt that for perfection of image and freedom from defect the glass support is as yet the best, there is no doubt, too, that there is a certain amount of halation accompanying the use of glass, which is often a serious objection to its use, particularly in landscape work. The celluloid film, however, owing to its thinness, is almost free from this objection, and, could it be obtained as free from defects as is the glass now in use by our best dry-plate makers, nothing better for photographic purposes could be desired, for its small weight, when compared with glass, gives it an immense advantage, especially when on a lengthened tour. Unfortunately, however, the celluloid of to-day is not yet as perfect as glass, and there is still room for considerable improvements in the methods of manufacture, although the character of the celluloid film now supplied is far superior to those of a few years back, when the large majority of negatives made on them were as full of spots as a coach dog. Although I have many very good negatives made on celluloid films, there is a considerable percentage where the defects of the celluloid are such as to preclude the negative from being used for purposes of enlargement. However, from samples which I have examined from time to time, I feel satisfied that the manufacture of celluloid sheets for photographic purposes is rapidly progressing towards perfection, and I do not think we shall have to wait very many years before it will be as cheap and as perfect as glass. Most of the coated celluloid films in cut sheets furnished within the past two years have been with a matt surface on one side and a smooth surface on the other, the emulsion being coated on one or the other side, according to the preference of the manufacturer. Those which I have used were coated on the smooth side. The matt-surface back is supposed to diminish the amount of halation, and also afforded a good and convenient ground for retouching. There is, and has been for some time past, a question in my mind, however, as to whether the matt or ground-glass surface does not to a certain extent interfere with the free transmission of light through the negative when printing, and so tend to diminish the brilliancy of the print, and therefore whether light would not pass more rapidly and actively through the clear glass of the shadows in a glass negative, and hence produce more dense and brilliant blacks. This applies more especially to plain silver and platinotype prints, where the tendency of the process is always to reduce contrast. I have heretofore used the matt-surface celluloid film exclusively. I think that with my next photographic expedition I shall make extended trial of celluloid without the matt surface, and which, being quite clear, is more of the character of a glass plate. I have made several experiments lately in comparing a smooth, clear celluloid film with one having a matt surface, the test being an exposure in an ordinary room, the lens being pointed directly at a well-lighted window, and the amount of halation resulting on each plate carefully compared. While my experiments have not been extended enough to warrant positive conclusions being drawn, the result has so far been quite sufficient to satisfy me there is no material advantage in the use of the matt-surface film, and in other respects it is not as perfect as the smooth-surface film, owing to its greater liability to show scratches.

Exposure.

And now for a few words regarding films and exposures. Up to this time I have used mainly the orthochromatic celluloid films prepared by John Carbutt, and his emulsions have always given me such satisfactory results that I can unhesitatingly recommend them. For landscape work I prefer a rather slow emulsion—not slower than twenty-three or faster than twenty-five (Carbutt sensitometer). But there is one vital principle never to be forgotten in the exposure of *all* orthochromatic emulsions. They must *always* be fully timed. An under-exposed orthochromatic plate or film is much more harsh and lacking in detail than an ordinary plate of the same speed would be when exposed under precisely similar circumstances. On the other hand, the orthochromatic plate, and even more so the film, will bear an amount of overtiming which would be simply ruinous to the ordinary plate. The matter of timing an exposure is one involving so many factors, all of which constantly vary, that it is almost impossible to lay down any positive dictum. But my own experience has been that with a film of twenty-three sensitomer (Carbutt's) and a good, rapid rectilinear lens at *f*-32, the exposure of five seconds on an ordinary sun-lighted landscape, with no special distance or deep shadows, would generally give me satisfactory results. Where a colour screen is used this exposure should be increased from five to twelve times, depending largely upon the depth of shadows in the subject.

The Colour Screen and its Preparation.

The colour screen for landscape work should be of a slight canary-yellow, and special care should be taken not to have it of too deep a tint, otherwise it will cut out too much of the blue rays, and a harsh negative, lacking in tone gradation, will result, while it will be necessary even then to make a much longer exposure than mentioned above. I have always prepared my own colour screens, using the following method. It is first necessary to procure glass perfectly flat and free from all striæ or bubbles, or, when placed before or behind the lens, its unequal density will refract the rays of light and thus distort the image. This is a *sine quâ non*. Thin plate glass that is used for the purpose of making colour cells, and animalculæ tanks, for demonstration with the gas microscope, is the best article for the purpose. After being cut in squares of the size desired, a square should be flowed on one side with a solution of a yellow aniline dye in celluloid varnish, using from five to eight grains of the dye to the fluid ounce of varnish, according to the depth of colour desired. I am in the habit of using a dye called "golden yellow," which is freely soluble in alcohol. The celluloid varnish is known in trade by a number of different fictitious names, such as "enameline," &c., &c. It is simply a solution of celluloid in mixtures of amyl acetate, petroleum benzine, alcohol and ether, mixed in varying proportions. It can be easily prepared on a small scale by cleaning off the emulsion from a spoiled celluloid film, cutting the film up in small strips, and dissolving these in a bottle in a mixture of one part (by measure) of amyl acetate, one part petroleum benzine, three parts alcohol and three parts of ether. The celluloid swells up and dissolves rather slowly, hence the bottle containing the mixture should be well shaken at intervals for several days. When the celluloid is all dissolved the liquid should be filtered through a little absorbent cotton to remove any loose flecks of dirt. This varnish gives a tough film, clear and free from transverse striæ, and is an excellent material for varnishing glass negatives or positives, being perfectly waterproof. To resume: The glass square, after having been flowed with the coloured varnish, in the same manner as when coating a plate with collodion, is allowed to "set" for a few moments, and then placed aside on a flat

surface until the varnish is perfectly hard and dry. Care must be taken to keep it covered while drying, so as to avoid dirt and dust settling on it. The coated plate is now placed on a level surface, film upward, and sufficient pure Canada balsam (white and free from dirt) poured on the plate to make a pool in the middle of the plate about one-fourth of its area. A fresh, clean glass square of the same size is next taken and gently lowered on the balsam and plate in the same manner that a cover glass is placed over a microscopic object, and then a gentle and even pressure exerted until all air is forced out, and the two glass surfaces are cemented together with the balsam and are in uniform contact. The cemented plates are now laid aside on a level surface and allowed to remain several weeks undisturbed until the balsam has thoroughly hardened. Then the edges are cleaned off, the exuded balsam being removed with a little benzine or benzole, and the edges bound with some strips of lantern-slide paper. This colour screen can be placed either before or behind the lens. If before, a special hood must be made to hold it. I therefore prefer to use it behind the lens, on the inside of the lens board, where it can be placed or removed in a few seconds. This can easily be arranged by having two small brass or wooden cleats made of this shape.

The edge is fastened down on the inside face of the lens board by means of a few small screws, and the colour screen will then slide easily up and down between the cleats.

A small sprig nail placed at the bottom acts as a stop, and prevents the colour screen from slipping down and out.

Orthochromatic Plates in Dull Weather.

One more point may be noted in regard to exposure. The *data* previously given were all based upon a clear, bright, sunshiny day being taken. But suppose the day to be overcast and cloudy. Under such circumstances the exposure on orthochromatic plates must be greatly lengthened, much more so than for ordinary plates under the same circumstances. For instance, if I gave twice or three times as much exposure on an overcast day (using an ordinary plate) as I would on a clear day, for an orthochromatic plate I should give from four to eight times as long, and if I did not do so I should have an undertimed plate. Most of my failures with orthochromatic films have been from this cause—undertiming on cloudy days. There seems, under these circumstances, to be an absence of certain light rays which affect quickly the orthochromatic emulsion. A very much longer exposure must be made to secure good results. I have frequently, after I discovered this, after making an exposure, made a duplicate in which I doubled the exposure, and almost invariably the longer-timed negative came out the best.

And now a few words in conclusion regarding development. Pyro, eikonogen, hydroquinone all give good results, depending upon the predilection and skill of the operator. I am inclined to favour the mixed developer of hydroquinone and eikonogen. With it I can secure fine detail and get also plenty of density when desired, and I think the combination particularly suited to orthochromatic emulsions.

Charles L. Mitchell, M.D.

Our Editorial Table.

The Amateur Photographer's Annual for 1892.

Hazell, Watson, & Viney, Limited.

To say that this volume is in every way an advance upon that of the previous year would be saying but little, for there is really no comparison between them. It does not bear any name as that of editor, although we may guess who he is. He has given an excellent summary of "Progress in Photographic Science in 1891," culled from various sources, all of which are acknowledged. In addition to this, we have two exhaustive essays, respectively, on "Architectural Photography," by Rev. T. Perkins, M.A., and "The Form and Composition of Landscape Photography," by Rev. F. C. Lambert, M.A., both of which are illustrated from negatives by their authors. It also contains a "Holiday Guide for Photographers," with a list of the dark rooms and dealers, where any, in the places mentioned, a feature that will prove attractive to many. The article on "Apparatus" is obviously a reproduction of the price-lists of certain dealers. The illustrations are numerous, and embrace one bromide print, one silver print, five collotypes, and several from process blocks. It is well got up. Price 2*s*.

Photographic Lenses and Sundries.

By Taylor, Taylor, & Hobson, Leicester.

This elegant booklet is something more than a mere catalogue of the firm's productions, for it also contains useful information relating to the principles of a lens's action, the standards of the Photographic Society of Great Britain for screw fittings and the preservation of lenses. We need scarcely add that it contains a full account of the lenses and other articles manufactured by the firm.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
August 8	Darlington	Trevelyan Hotel, Darlington.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

July 28,—Mr. H. Snowden Ward in the chair.

Mr. G. Ruthven was elected a member.

It was announced that Miss Catharine Weed Barnes and Dr. Charles L. Mitchell had promised to read papers before the Association.

Questions.

A question from the box asked, "What is the meaning of 'cutting the shadows' in a plate?" It appeared that the question referred to an editorial notice of the Barnet plates by a contemporary, in the course of which pyro soda was said to "cut the shadows."

Another question was: "In making gelatine emulsion, what is the best method of adding silver nitrate in order to secure uniformity of the precipitated particles?"

Mr. W. E. Debenham would have gelatine in both solutions.

Mr. G. W. Atkins asked if the silver nitrate would not injure the gelatine?

Mr. Debenham replied that emulsions made that way were very good—Captain Abney recommended it.

Reducing Prints.

Question No. 3: "Please state the best formula for reducing silver prints, both albumen and gelatino-chloride."

Mr. Debenham suggested fresh hypo for albumen prints.

Mr. F. A. Bridge stated that Mr. Dunmore recommended mercury bichloride.

Mr. R. P. Drage mentioned that he had had gelatino-chloride prints dry a rusty black, and that he found a weak solution of mercury bichloride converted them into a mauvish tint. The prints had kept nine months without alteration.

Mr. T. Bolas suggested the use of a weak solution of iodine and hypo.

Mr. Debenham had tried cyanide, and got graininess and a nasty colour.

Mr. E. W. Parfitt had reduced silver chloride prints with Farmer's solution. It had a tendency to attack the half-tones first.

Mr. Drage found that ferridcyanide and hypo would not injure any kind of print.

Flashlight Portrait of Miss Barnes.

The Chairman exhibited a flashlight portrait of Miss Catharine Weed Barnes taken by Mr. Robert Slingsby, of Lincoln. The exposure, with eight lamps, would be about one and a half seconds. All the lamps were placed at the same distance from the sitter, and had reflectors.

Mr. B. Foulkes-Winks exhibited a patent album for holding unmounted prints, which appeared to resemble an ordinary portrait album.

The meeting subsequently adjourned.

Amateur Photographic Association.—A Council Meeting to award the prizes was held on Wednesday, July 27, at 58, Pall Mall, His Highness the Duke of Teck in the chair. The following members were elected:—The Viscount Maitland, Mrs. E. G. Wrigley, Messrs. T. K. Mellor, E. F. Scougal, M.D., A. H. D. Steele,—Craigie, E. Kennard, W. J. Harrison, and Miss E. A. Sykes. Mr. Melhuish, the Hon. Secretary, then laid before the meeting the pictures for the current year, which had been arranged and classified by Mr. Glaisher. There are 152 pictures in Class I, being more "first class" pictures than had been contributed in any previous year. They are as follows:—C. Stephens, 6; Lord de Ros, 2; R. Murray, 9; F. E. Currey, 2; W. S. Hobson, 18; Major Board, 1; General Sladen, 1; R. O. Milne, 18; R. Leventhorpe, 12; M. de Dêchy, 6; W. Gaddum, 3; J. C. Cohen, 6; Colonel Foster, 3; F. G. Smart, 7; the Vicomte de Condeixa, 9; H. O. Hutchinson, 5; F.

Wrigley, 2; Miss Mahon, 3; A. R. Dresser, 9; H. Emmons, 3; E. F. Scougal, M.D., 1; the Viscount Maitland, 8; and W. Jerome Harrison, 18. The rest of the pictures were comprised in Classes 2, 3, and 4. The following prizes were awarded:—First prize to the Vicomte de Condeixa, a large silver goblet, for Nos. 2, 3, 5, 10, and 13; R. O. Milne, a silver goblet, for Nos. 7, 15, 25, 26, and 31; C. Stephens, an album, handsomely bound, for Nos. 67, 69, and 70; M. de Déchy, a large silver medal, for Nos. 1, 3, 5, and 6; A. R. Dresser, an album, handsomely bound, for Nos. 1, 5, 33, and 79; the Viscount Maitland, a medal, for Nos. 2, 8, and 10; W. S. Hobson, a silver goblet, for Nos. 372, 371, and 378; R. Leventhorpe, a picture in frame, for Nos. 223, 224, and 228; W. J. Harrison, a large silver medal, for Nos. 15, 31, 39, 43, and 44; F. G. Smart, an album, handsomely bound, for Nos. 38, 39, and 45; Colonel Foster, a picture in frame, for No. 3; J. C. Cohen, a medal, for Nos. 5, 7, and 8; H. O. Hotchinson, an album, handsomely bound, for Nos. 2 and 5; W. Gaddum, a medal, for No. 178; H. Emmons, a medal, for Nos. 3 and 4; R. Murray, a medal, for Nos. 276 and 284. A vote of thanks was passed to Mr. Glaisher for the time and care he had bestowed on the arrangement and classification of the pictures. The pictures are now on view at the offices of the Society, 53, Pall Mall, opposite Marlborough House.

Liverpool Amateur Photographic Association.—What may be termed the private view of the newly acquired premises of this Association in Eberle-street took place on July 26. The old quarters of the Association in Lord-street, although pleasant enough when reached, were far too small for the growing needs of the Association, and it was decided some time ago to cast about for more convenient rooms. Percy-buildings, Eberle-street, were eventually fixed upon, and the building is now practically divided between the Artists' Club and the Photographic Association. The Association is to be most heartily congratulated alike upon the extent, the comfort, and the artistic beauty of their new abode. The rooms, in which special accommodation has been provided for lady members, are approached from two entrances, and have been decorated throughout with the utmost taste and delicacy. Upon the walls, and crowding every square inch of space, are to be seen some of the finest specimens of the photographic art ever printed. Downstairs, everything has been done to please the eye; upstairs nothing has been left undone to give the members of the Association every opportunity to approach perfection in the developing, the printing, the finishing, and the hundred other practical details which go to make the modern photograph so beautiful a work of art. The visitors to the Association were received by the President, Mr. W. Tomkinson, Mr. Paul Lange, Mr. Woolfall (who has done yeoman service in the fitting up and decoration of the new premises), and other prominent members of the executive. It may be safely said that, with the exception of the Camera Club, in London, no photographic body in the United Kingdom has such commodious and such artistic surroundings as the Liverpool Photographic Association. At the monthly meeting on Thursday, July 28, Mr. B. J. Sayce presided, and there was a large attendance of members. Mr. B. J. Sayce gave a report of the excursion to Emral and Erbistock, which took place on July 24, at which thirty-six members and friends were present. About 120 exposures were made, some of the work, which was very beautiful, being shown during the evening. Mr. P. Bebbington, of 12, Cornbrook Park-road, Chester-road, Manchester, attended, and explained his novel "Trafford" camera. Mr. Paul Lange showed his new American 5×4 camera, and Mr. Sanders, of Mount Pleasant, exhibited his novel and ingenious opera-glass camera, capable of making twenty-four exposures, as well as being useful as a telescope. The Eastman Company's new printing-out paper sample packet, and the Paget Prize Plate Company's sample packet of plates were distributed among the members. Mr. Lange gave a practical and enjoyable demonstration of the Platinotype Company's new cold-bath process, with the use of glycerine and brush manipulation. At the close, the Chairman spoke of the arduous work done by Mr. J. Woolfall in arranging the new premises, which would prove of incalculable value to the members. The membership is now 300, and is increasing every month. Mr. John H. Welch, in the absence of Mr. Illingworth, the secretary, conducted the proceedings, which were highly enjoyed.

Foochow Camera Club.—May 18, the President (Mr. G. Siemssen) in the chair.—The minutes of the last meeting were read by the Hon. Secretary, Mr. Mencarini, and confirmed. Mr. Rentzsch read a paper on *The Art of Grouping*, and said: "In a place like Foochow, where we have so few amateur photographers, it is somewhat difficult to find a subject which shall be interesting to all the members of the Club. In hunting round to find something suitable, Mr. Mencarini and myself thought that perhaps a few words on the posing of groups might be interesting, for, although it is to be regretted there are so few actual amateur photographers in the place, still we all at times find ourselves members of a group, and of professional help as regards the posing there is none. The poor Jap is silent in his one language, and it is difficult to see, unless he lifted the members of a group about like a lot of tailors' dummies, how he possibly could pose it, and as for the Chinese photographers, all art instinct is usually as absent from the Chinese character as the idea of honesty and truth; so, there being no professional help for us, the best thing we can do is to endeavour to help ourselves, and try and fix in our minds the few fundamental rules, by no means difficult to remember, as to how a group should be arranged. After a few words on this subject, I will, with your permission, arrange you as a group as badly as possible, and afterwards correctly, as well as I can, and Mr. Mencarini will take a flashlight picture of both, which he will proceed to develop with the very last of seven-syllabled developers. The first thing to consider is the background. Trees, as far as possible, should be avoided; the light falling on the leaves causes white spots in the picture, producing a very disagreeable effect. A light-coloured wall is as good as anything, or, better still, the front of a house, only then the group should be placed well in front of it, so that the building may be slightly out of focus, and not by its detail detract from the figures, which, be it remembered, should be portraits. The members of the group should be cautioned on no account to look higher than the top of the camera, and those on the right and left should look at it not with the eyes only, but by slightly turning the head. As far as it can possibly be avoided, do not have two heads next to one another on the same level, and do not have two ladies in light-coloured dress one beside the other—separate them by some one in the dark clothes. Arrange the group so that tall persons are in the middle, and short persons at each end, and in the case of ladies wearing white dresses, or colours which are white to the photographic eye, place them in the front row. The professional photographer frequently says, 'Please put on the beginning of a smile;' but as this usually results in a complete grin, and, in some cases, even a grimace, it seems to me far better to tell people to lightly close the lips, for nothing looks worse than to see a lot of people with their mouths half open in a semi-slobbering condition. It is impossible in a short paper like the present to enter into the deeper portion of the subject regarding the balance of the picture, and so on; but, if the foregoing rules are remembered, there may be some hope that the average group taken in Foochow will be somewhat improved. The preceding rules may be summarised as follows:—No trees in the background. No looking higher than the top of the camera. No two adjoining heads on the same level. And no mouths open."

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 13,857.—"Improvements in Springs for Use in Photographic Changing Boxes." A. S. Newman and J. Guardia.—*Dated July* 30, 1892.

PATENTS COMPLETED.

Improvements in Photographic Lenses or Objectives and in Apparatus connected therewith.

No. 10,748. Andrew John Stuart, Bretlands, Rusthall, Tunbridge Wells. *July* 9, 1892.

This invention consists in obstructing or cutting off the light by any means whatever from the central portion of the surface of photographic lenses or objectives, single or compound.

In obstructing by any means whatever the rays of light which fall on the central portion of the surface of such photographic lenses or objectives, so that the image will be formed by the rays which fall upon that portion of the lens which is outside the part so obstructed or covered up. The shape of such obstruction may be circular or oval, or of any other form.

Such obstruction may be caused by any mechanical means whatever; for instance, by a disc of metal or of any other substance in front of the lens, or by a disc of tinfoil, or a disc or spot of paint or of any other substance adhering to the lens, or by cutting the lens in such a manner as to obstruct the rays.

In the case of compound lenses or objectives, such obstruction may be applied to any or all the lenses of which the compound lens is constructed, or to the whole as a compound lens.

Patent protection is sought for the above-mentioned, as well as for all other possible ways of causing the obstruction described above.

The means of obstruction may be of such construction as to admit of the area obstructed being varied at pleasure by the use of the principle of the "iris diaphragm," or by a rotating carrier bearing discs of different sizes. Protection is sought for the application of these or of any other mechanical means for enlarging or reducing the area obstructed at pleasure.

The means by which such obstruction of light is obtained may, for the sake of convenience, be called "a central diaphragm," and will hereinafter be referred to by that phrase.

Such "central diaphragm," in whatever manner constructed, may be combined with the ordinary diaphragm as now in general use, so as to enlarge or contract the area of the lens surface exposed, and by which the picture is formed, so also as to limit the rays falling upon the outer portions of the plate to those coming from one portion only of the lens, or of so much of it as is exposed.

It is the combination of this use of the ordinary diaphragm, which is a part of the ordinary construction of photographic lenses, with the obstruction in the centre of the aperture by the "central diaphragm," which is the most important and novel feature in the present improvement.

It is believed that by this invention a better illumination will be obtained, especially in the outer parts of the field or plate, a more even illumination resulting in more even development, and in more equal density in the picture when finished, better definition, in the outer portions of the field especially, more rapidity in the lens, with less distortion and more flatness of field.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—1. Protection for the use of the "central diaphragm" as above described in the construction or use of photographic lenses or combinations of lenses or objectives as such are now constructed or used. 2. For the use of the said "central diaphragm" either by itself or in combination with diaphragms of the ordinary kind now in use, in the manufacture or use of photographic lenses or objectives, whether single or compound. 3. The application of the principle of the iris diaphragm, or of a rotating carrier bearing discs of different sizes, or of any other mechanical contrivance for varying at pleasure the area obstructed by the "central diaphragm."

[If the patentee will call at our office by appointment, we will show him several articles, in this and other journals, some of them written considerably over a quarter of a century since, in which the use of the "central diaphragm" is advocated and its construction described.—Ed.]

Correspondence.

THIO-CARBAMIDE REVERSALS—YELLOW SCREENS.

To the EDITOR.

SIR,—With reference to the note on page 374 of THE BRITISH JOURNAL OF PHOTOGRAPHY for June 10th, regarding Mons. Fourtier's failure to work the reversed process with thio-sinamine, I very much regret that I am unable to give him any further information than that given in THE BRITISH JOURNAL OF PHOTOGRAPHY for September, 1890, pages 602 and 613, and in 1891, page 261; also in last year's ALMANAC, as well as in other journals, English and French.

I should, however, advise him to try with Professor Emerson Reynolds' compound salt of thio-carbamide and ammonium bromide, referred to in THE BRITISH JOURNAL OF PHOTOGRAPHY, 1890, page 673, which has consistently given me better results than any other of the thio-carbamides tried. It can be obtained from Messrs. Hopkin & Williams, and is conveniently soluble in the proportion of 1 to 100 in alcohol. A few drops of this solution may be added to a developer made of—

Eikonogen	1 part.
Lithia Carbonate	1 ,,
Soda sulphite	1 ,,
Water	100 parts.

Each kind of dry plate and subject requires its own special treatment, and as a rule some preliminary oxidation of the film is necessary, but I have no further definite information to give.

I hoped to have resumed this work on my return here, in order to find out a reliable and certain method of using the thio-carbamides for reversals, but have hitherto been unable to do so. Trials made with collodio-bromide emulsion have given prospect of success, and I shall probably turn my attention in this direction in connexion with other work with collodio-bromide emulsions. In the meantime, if I can render Mons. Fourtier any assistance in the matter I shall be very glad to do so if he will communicate with me, and let me know his special difficulties.

I observe in the same number of THE BRITISH JOURNAL OF PHOTOGRAPHY an article on "Yellow Screens for Orthochromatic Work," in which compound screens of gelatine and collodion are described. I have not a very large experience in this question, but what I have leads me strongly to recommend good glass screens in preference to any film, though film screens may be useful for obtaining special tints that could be obtained in no other way. I find that with collodion or gelatine screens there is always more or less loss of definition. The best screens of this kind I have used were made of clear thin talc or mica coated with a *cold drying* crystal varnish made of benzole and sandarac or dammar coloured with annatto, turmeric, or other colouring matters soluble in benzole, which, unfortunately, most of the yellow "coal tar" dyes are not. A good spirit varnish or lacquer would probably answer as well, but all spirit varnishes are difficult to use in the moist Bengal climate. Varnish is far more structureless than collodion. The formula used for the varnish was—

Turmeric varnish	2 parts.
Annatto	1 part.
Kamala	1 ,,

The turmeric varnish has a greenish tinge, the annatto a reddish tinge, and the kamala (made from a powder obtained from *Rottleria tinctoria*) a neutral yellow. By varying the proportions different tints can be obtained. Other yellow dye stuffs soluble in benzole could also be used. This varnish applied to worked glass gave very good results for copying work, when placed behind the lens. The coated linen can be used in double diaphragms.

Suitable yellow glasses are now so easily obtained, and are so effective and uniform in use that I would certainly recommend them in preference to any varnished screen, which, even if it does not damage the definition of the image, is always liable to injury, and to change of colour by fading of the dyes.—I am, yours, &c., J. WATERHOUSE.

Survey of India Office, Calcutta, July 12, 1892.

[In the current number of the *Photo-Gazette* (Paris), M. Fourtier details some successful reversal experiments with a different sample of thio-sinamine to that which he employed on the former occasion.—ED.]

THE FOCUSSING SCREEN THE BEST ACTINOGRAPH.

To the EDITOR.

SIR,—Permit me through the medium of your valuable paper to endorse the opinions of Mr. Bedding in his paper to the North Middlesex Photographic Society, on the above subject.

I commenced photography some seven or eight years ago, and all my friends and acquaintances knew about as much of the subject as I did myself, which was absolutely nothing at all. My knowledge therefore had to be gained chiefly by the greatest of all teachers—experience. I certainly gained a certain amount of information from the manuals published on photography, but my knowledge of "exposure" was all got by practical experience. I quite agree with Mr. Bedding when he says, "that a man who takes up photography will surmount the difficulties of exposure by the aid of his own brains, or not at all." I have never used an actinograph, or anything of the kind, and never mean to, as I place more reliance on my own judgment of what exposure is necessary by the appearance of the picture as presented to me on the focussing screen of my camera. During my comparatively short experience I have come across many amateurs who always, when making an exposure, use one or other of these "so-called aids," and who, for the life of them could not correctly expose a plate without it, and in many cases when they have used it, find their negatives improperly exposed. Exposure-meters always put me in mind of "ready reckoners" in a counting house, which the clerks invariably fly to if there is a small calculation to make instead of using their own brains.

My advice to all brother amateurs is, use your own brains, cultivate your memory of pictures you have taken before, compare mentally the aspect of the one with the other, and form your own judgment of what exposure should be given, and the experience thus gained will stand you in better stead than all the actinometers put together.

In conclusion, I should like to contribute my small mead of praise for the able manner in which Mr. Bedding treated the subject, and have no doubt but that the paper will be read with great pleasure, both by professionals and amateurs alike.—I am, yours, &c., W. A. COLE.

Berlin House, Moseley, Birmingham, July 30, 1892.

LOSS OF DENSITY IN FIXING.

To the EDITOR.

SIR,—Your apology for putting *account* instead of *atone* has been noted by the *whole* French press, and war, with all of its modern improvements, has once more been averted.

Your notice in regard to losing of intensity in negatives in the fixing bath may be correct; yet, call it as you like, the fact remains that seemingly or not some makers' dry plates have to be pushed much further than others, and this fact ought to be recorded on the package, I think. Light in the dark room may be taken as an excuse with some, but probably with very few. If a candle is used, it is pretty much always the same, and, when a lamp or gas flame, this is pretty much always regulated at the same height by any half careful operator, and made to suit his lantern; and, as to this last one, I do not think that the red glasses are replaced more than when absolutely necessary, and that is usually (here in France) when broken. I use gaslight, and that is even enough.

But where you are wrong altogether is when you say that a wet negative appears denser than a dry one. The reverse is an absolute fact with us at least, and I do not think that I am an exception. This can, however, be very easily understood and explained. In a wet negative the gelatine is largely swollen, the particles of reduced silver very much apart, and light passes very freely, so much so that in shadows some details will not show at all when wet, while when dry they will be most apparent. I do not think I will be contradicted on that point.—I am, yours, &c., A. LEVY.

Asnières, July 23, 1892.

To the EDITOR.

SIR,—Having noticed that an old acid fixing bath dissolved the whole of the silver from a plate in the course of a few days, the following trials were made to ascertain to what extent reduction would be likely to take place during the short time required for fixing negatives. Pieces of a plate having upon it the following densities: 1·46, 1·00, and ·58, were placed in new and old acid fixing baths. After sixty hours in the new bath the densities were reduced to 1·35, ·9, and ·49, and after forty-eight hours in the old bath to ·54, ·30, and ·16. Evidently the loss of density in half an hour must be very slight indeed.—I am, yours, &c.,

Red Hill, August 1, 1892. JOHN STERRY.

SPEED OF PLATES.

To the EDITOR.

SIR,—At the end of his letter in your last issue, Mr. Watkins asks, "What is the meaning of development factor?"

On page 10 of Messrs. Hurter & Driffield's paper, second column, line ten, it is described as a "constant depending upon the time of development," and it is afterwards represented by γ in the various formulæ. The necessity for its consideration and its value are found on pages 11 and 13, and its most important practical bearing is mentioned on the last page.

Perhaps Mr. Watkins will understand its meaning best by my stating that the development factor includes that which he asserts Messrs. Hurter & Driffield have omitted, where he says, "This method leaves entirely out of the question, whether this correct scale of gradation has sufficient opacity in the highest terms of its scale to provide practical

printing density in a negative." It is, in fact, for practical purposes, the measure of the printing value of a negative at any particular stage of development; or, in other words, it indicates the difference in result which is obtained with different plates, developed for the same time, or, if desired, the same plate for different times.

The object of my letter (July 8) was to show that Mr. Watkins' proposed method of developing for a definite time would fail to give the desired results, because equal densities would not necessarily be obtained with plates of equal speed, as shown by plates 2 and 4, the latter requiring a longer time of development to obtain equal densities.

With regard to plate 3, had Mr. Watkins understood the meaning of the development factor, and had also noticed the following upon page 13 of Messrs. Hurter & Driffield's paper, "Experiments which we have made indicate that for the production of artistic effects on ordinary silver chloride paper, it is necessary to prolong the development, γ is greater than 1, and nearly reaches the value 2," he would have seen that none of the plates 1 to 4 had received sufficient development to be suitable for either silver or platinum paper printing, and he would not have so hastily condemned plate 3.

The longest development of that plate of which I have any record gives results as under, and, though by no means the highest densities, which could easily be obtained, it shows the density 1·73 (opacity 54) nearly reached within the correct period of the plate.

C. M. S.	2½	5	10	20	40
Density	·81	1·23	1·62	1·96	2·3
Opacity	6·45	16·6	41·7	91·2	199

Inertia, ·65. Actinograph speed, 52. Development factor, 1·4.

The opacities are added because Mr. Watkins seems to think most can be learnt from them. If so, it is necessary to point out that in the table he gives all the densities over 2·0 have been incorrectly translated.

"Certain classes of emulsions," Mr. Watkins says, when tested by Messrs. Hurter & Driffield's method, show a "sensitiveness not substantiated when the plate is exposed in the camera." None such have come under my notice during twelve months' trials; and, as to the old red-label Ilford plates he mentions, Messrs. Hurter & Driffield said, "we found it very *difficult* to ascertain their true speed in the camera on account of the difficulty in securing adequate density," from which it is evident that they overcame the difficulties which Mr. Watkins found insuperable.

I cannot agree with the statement that "there is very little that is absolute about the science of photography," for already much has been proved.—I am, yours, &c.,

JOHN STZABY.

Red Hill, August 1, 1892.

CONCERNING PETITIONS PERTAINING TO THE PHOTOGRAPHIC PRIVILEGES AT THE WORLD'S COLUMBIAN EXPOSITION.

To the EDITOR.

SIR,—It is very gratifying to those engaged in the endeavour to secure the general right of photographing at the Chicago Exposition to note the unanimous action of the Photographic Convention of the United Kingdom in protesting against the restriction of the privilege, as has been proposed by the Ways and Means Committee. This vote, together with the many petitions which are being received from other English societies, will have a beneficial influence on our cause. Since this agitation was begun there are indications that the wishes of the thousands of photographers will be respected.

Having learned, through an oversight on the part of my clerk, that many of the petitions were mailed short of postage to the English societies, I would ask for a short space in your valuable JOURNAL to say to any who were obliged to pay double rates that the same will be refunded to them by Miss C. W. Barnes, if addressed to care of the JOURNAL.

The more foreign societies we can hear from, the greater will be the weight of the petition.

There is a principle involved that has never been thought of before, and in urging greater freedom in the exercise of the photographic privilege at public places we shall undoubtedly, should we succeed, benefit not only the amateurs, but all photographers and manufacturers. Any photographers may send me their names to be affixed to the petition, whether or not they belong to a club or society. All are welcome to participate in aiding this movement.—I am, yours, &c.,

F. C. BEACH.

239, *Fifth-avenue, New York, July* 26, 1892.

PERMANENCY OF GELATINO-CHLORIDE PRINTS.

To the EDITOR.

SIR,—The enclosed print is a proof that Ilford P.O.P. is likely to be permanent under ordinary conditions. The print was made last December, and placed, with one half covered up, in a south window; it has been taken down several times, soaked in water, and replaced wet.

The print is a poor one, from a thin negative; just the kind of print one might expect to fade and turn yellow. You will see there is no visible change between the half that has been kept covered and the other, and the whites are as pure as when first made. The print was toned in a borax bath, which in my hands gives good results with this paper.—I am, yours, &c.,

H. G. M. CONYBEARE.

The Hut, Ingatestone, July 31, 1892.

EASTMAN PELLICLE.

To the EDITOR.

SIR,—You noticed, not long ago, some negatives of Eastman pellicle on a film two years in the roll holder and three years in stock; and I send you to-day some made on the old American negative paper, coated in April, 1885. I exposed four films, and send you the whole.—I am, yours, &c.,

W. J. STILLMAN.

Rome, July 29, 1892.

[The quality of the negatives is excellent, and decidedly attests the remarkable keeping properties of the Eastman negative paper.—ED.]

THE COLLECTION OF RESIDUES.

To the EDITOR.

SIR,—Referring to your leader in the last issue of THE BRITISH JOURNAL OF PHOTOGRAPHY about collecting photographic residues, it will be found that gelatine exercises considerable influence in delaying the precipitation of dilute solutions of silver chloride, whether the precipitant has been salt or hydrochloric acid. It is a most difficult matter to precipitate thoroughly, to say nothing of rapidly, any very dilute solution of silver salt in the presence of undecomposed gelatine. Gelatine may be introduced by washings of vessels used in the preparation of emulsions or in other manners. The waste solutions of photographic laboratories are generally of a very miscellaneous character, and it will save trouble to bear in mind that any containing gelatine should have that colloid thoroughly decomposed before adding it to the bulk of waste, as when diffused in a large quantity of water it is not so easily decomposed as when it is in a more concentrated form.

I am unprepared to say if the addition of lead acetate would get over the difficulty, not having tried it; but, as the action is purely physical, it is merely a question will the extra weight and coarseness of the precipitate overcome the viscosity of the gelatine. I merely mention this, as gelatine *has* to be reckoned for in the collection of residues in ordinary procedure.—I am, yours, &c.,

EDWARD DUNMORE.

August 2, 1892.

ESTIMATION OF SILVER NITRATE.

To the EDITOR.

SIR,—Thinking that perhaps the results of an estimation by *weight* of a sample of cheap silver nitrate in the market might be of interest, I venture to send the numerical details of one undertaken by myself some months ago in consequence of an account of the then market value of silver, as contained in an article, I think, in your valuable JOURNAL.

The price paid for this particular sample was 2*s.* 5½*d.* or 2*s.* 6*d.* for the *single ounce*, and was labelled as pure recrystallised nitrate of silver, and, as the results obtained in actual practice, when used as a sensitising bath for wet plates, are in the highest degree satisfactory, argues, I think, further proof of the results of the estimation being fairly accurate.

ESTIMATION OF Ag IN $AgNO_3$.

Weighing bottle + $AgNO_3$ = 8·394 grammes,
" " 7·142 "
Weight of $AgNO_3$ taken ∴ = 1·252 "

Weight after precipitating as chloride, washing, drying, and fusing:—
Weight of porcelain crucible + Ag Cl = 13·654 grammes,
" " " = 12·599 "
1·055
Less ash of filter paper ·00866 "
Weight of Ag Cl found 1·05134 "

∴ Ag Cl Ag Cl Ag
143·5 : 1·05134 :: 108 : x = ·7912 of silver.
∴ 1·252 : 100 :: ·7912 : x % of silver in the weight of silver nitrate taken = 63·19 % of silver.

Silver calculated theoretically 63·53 grammes,
" found experimentally 63·19 "
Difference ·34

If you should consider this of any value, please note that it is only the result of *one*, although very carefully made, estimation.—I am, yours, &c.,

E. SENIOR,
Honours Medallist, and late Student Polytechnic School of Photography.

**** Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PROFESSOR E. STEBBING.—Many thanks.

A. CAMPBELL.—Make the sulphite solution decidedly acid.

A. L. W.—A solution of "ordinary sulphite of soda" should be neutral to test paper.

S. ANDREWS.—In using matt varnish, the plate should not be warmed, either before or after its application.

HARRY VINCENT.—Precipitate the silver in the solution with potassium sulphide. You will then obtain the silver as sulphide.

FERRO.—No; iron development is by no means extinct. It is extensively employed on the Continent for both negative and positive work.

S. A. B.—If the instrument is in good condition, it is very cheap at the price asked. Have an undertaking that it is by the maker whose name it bears.

H. T.—Possibly the lead is the primary cause of the fugitiveness of your prints. We should recommend you to revert to the use of porcelain dishes.

SIMPLEX (Penshurst).—An over-printed silver print may be sensibly reduced by treating it with a weak solution of bichloride of mercury. Fixation is unnecessary.

J. W. says: "Can you give me the address of a manufacturer of dry ferrotype plates?"—Mr. L. Nievsky supplies such plates. Address him, care of Mr. Fallowfield, Charing Cross-road, W.C.

C. J. T.—We should think that the print with the blue spots had been exposed to light during toning, and that the toning solution had not been kept in motion. Both prints appear to be over-toned.

E. E. H. asks if the patent for stannotype process has expired, or whether it is still in force.—We have an idea that it lapsed a year or so ago, but we are not sure. The information can be obtained at the Patent Office.

H. COLEBROOK.—Coloured screens for orthochromatic work may be obtained of Mr. J. R. Gotz, 19, Buckingham-street, Strand, W.C. We believe they are to be had in various tints. They are comparatively inexpensive.

H. A. C.—If the colour on the mount comes off as soon as it is damped, the boards are not suitable for photographs. Better obtain mounts made for the purpose. They may cost a little more, but will prove cheaper in the end.

TOURIST.—There are no means, when purchasing views of local scenery, of knowing if they will fade quickly or not. Of course, if they are produced by a mechanical process, such as collotype, as some are, there is no fear of their fading.

HADJE.—The best advice we can give you is to procure a manual of photography that treats practically of the wet collodion process. It is elementary instruction you require. An early edition of Jabez Hughes, or any other manual, will answer your requirements.

W. MCARTHUR. The staining of the negatives does not arise from any defect in the plates, but is caused by the manipulations; *i.e.*, the fault is yours. The negatives were insufficiently washed between the different operations. Greater care in future will avoid the stains.

J. A. (York).—The fixing solution from dry plates is certainly worth saving, even in a not very large business, and it involves little or no extra trouble. All that is necessary is to pour the old solution into that used for fixing prints. One receptacle will then do for both solutions.

ARTIST.—Bromide, carbon, and platinotype pictures are finished with ordinary water colours; no special medium is required beyond occasionally a little gum water. As you fail to get the effect you desire, why not take a few lessons from a professional?—it might possibly save you much trouble.

R. BIDGOOD says: "I have an old document on parchment to copy, which is very yellow, and I cannot get a brillian negative. Do you think that a better result could be got by using plates orthochromatised as described on p. 774 of the ALMANAC?"—Yes; we have no doubt on the subject.

P. YOUNG.—1. In using a portrait lens for enlarging from small negatives the back combination should be next the negative. 2. If the lens is what is known as a cabinet lens, no stops ought to be required when enlarging from a *carte*-size negative. 3. The suggested arrangement will do quite well.

ALPHA.—There is no novelty in a studio that can be revolved on a centre. A patent for a revolving studio would not be valid. It is quite possible that a patent might be good for any special method of mounting it or means of rotating it. If an invention be old, although it can be patented, the patent will not be valid.

DUBIOUS.—Gelatino-chloride prints, toned with the combined toning and fixing bath (which differs materially from the combined bath formerly employed with albumen prints) appear to us to have as reasonable a chance of permanency as other prints. The old combined bath was superseded by alkaline gold toning.

INQUIRER.—Without a chemical investigation—which we have not time to make; indeed, we do not undertake such work—it is impossible to say whether the mount contains deleterious matters or not. Your best way will be to send some of the suspected mounts to an analytical chemist, and get him to report upon them.

PRINTER.—You are probably correct in stating that Mr. J. W. Swan was the first to employ a gelatino-bromide emulsion for developable prints, but you are wrong in concluding that he was the first to use gelatine as a vehicle for any printing process whatever. In 1865 a patent was obtained by Messrs. Smith & Co. for the application of printing-out gelatino-chloride emulsion to paper, wood, and other supports.

STAFFORD.—The best method of cleaning the films of spoilt negatives off th glass is to soak them for a day or so in cold water, and then to immerse them in hot. The gelatine will then be dissolved. This treatment will also answer with negatives that have been varnished. We strongly suspect however, that you will have all your trouble for nothing, as we doubt very much if any plate-maker will allow you anything for the glass.

R. C. E. says: "I have frequently seen permanganate of potash recommended for intensifying carbon transparencies, would it not answer also for the intensification of lantern slides made on the ordinary plates?"—It would not answer. With the permanganate it is the gelatine that is acted upon, and that is a uniform film on a bromide plate. In a carbon picture it is of varying thickness. In the highest lights there is no gelatine at all.

W. W. says: "The toning bath I made up the other day has become quite brown, although it was made in the same way as usual. The only difference was that it was a fresh lot of distilled water obtained from a local druggist. Can you suggest any reason for its behaviour except the water?"—Supposing the vessel in which the bath was prepared was clean, there is small doubt the water was at fault. A local druggist's is not the most reliable place to obtain pure distilled water.

J. P. MILNES writes: "Can you kindly inform me as to the best method for placing another person in a group? I took a group the other day, and, to complete the picture, the party wish a photograph of a brother now in Australia put in the picture. Can you inform me as to the best and neatest way to proceed? I have left a small space behind just to get his head and shoulders in."—In reply: Take a negative of the portrait to the scale of the others in the picture, and of the same density. When finished, immerse in water containing a few drops of hydrofluoric acid per ounce. In a few minutes the film will leave the glass and may be floated on a sheet of hard paper face downward. When dry it can be cut, paper and all, to fit a place scraped out of the negative to receive it. A little gum will serve to attach it, when the paper must be removed.

WEST LONDON PHOTOGRAPHIC SOCIETY.—August 6, West Drayton, to meet the Ealing Photographic Society.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—August 11, *Development of Instantaneous Exposures.* 18, *Stereoscopic Photography, with Specimens.*

PHOTOGRAPHIC CLUB.—August 10, *Opal Pictures.* 17, *Photographing Interiors.* Outing, Saturday, August 6, High Barnet; train from Broad-street, eight minutes past two; Finsbury Park, twenty-five minutes past two.

THE DEVELOPAN is a portable dish for the development of negatives in an ordinary apartment. The apparatus consists of a tray and cover. Each tray is provided with a pane of non-actinic glass, the whole forming a transparent box, which, being held up before the flame of a candle or lamp, enables the operator to perceive the progress of development. The negative having been transferred to the "Developan," the developing solution is poured into it by means of the nozzle, a perforated screen inside preventing the passage of any light. The "Developan" is neatly constructed, and should prove effective. It is patented by M. A. Desbontin, and sold by the Developan Manufacturing Company, of 130, Charing Cross-road, W.C.

HAND CAMERA PICTURES AT THE CONVENTION.—Mr. W. D. Welford informs us that he is desirous of arranging a meeting in London, on or about the 10th inst., of those who had hand cameras at the Convention. He proposes that they should attend a non-formal gathering, and those who cannot should send their prints. All the hand-camera men at the Convention, and any others interested, are invited to send a postcard to Mr. Welford (47, Hagley-road, Birmingham), and he will, in return, state the exact date, place, and time of the meeting. A portfolio or album of all the shots secured by hand cameras at the Convention would prove of interest, as they are so completely different to ordinary camera work, and the variety of subject much greater. Mr. Welford will make a suggestion on this point.

**** With the* JOURNAL *of Friday next will be presented a collotype reproduction of the group of the members of the Photographic Convention of the United Kingdom assembled at Edinburgh on July* 15. *The picture was taken by Mr. Alexander Ayton, jun., and comprises about* 130 *members, probably the largest number ever included in a Convention group.*

JOURNAL OF PHOTOGRAPHY.

No. 1684. Vol. XXXIX.—AUGUST 12, 1892.

EQUALISING THE ILLUMINATION OF NEGATIVES.

It is never but with the greatest reluctance that we append to the patent specification of a worthy invention any remark as to its being lacking in novelty, and consequently being invalid.

This we felt compelled to do last week when publishing the details of the invention, by Mr. Andrew John Stuart, of what he designates a "Central Diaphragm" for a photographic lens. The leading feature in the invention of this gentleman consists in obstructing or cutting off the light from the central portion of the lens, so that the image shall be formed by the rays which fall upon that portion of the lens outside the part so obstructed or covered up.

Although the patentee does not describe or explain by what means such an opaque diaphragm conduces to the production of a photograph more evenly lighted than can be secured without such an expedient, yet we hope here to supply the hiatus, although in doing so it will, we fear, only stamp in more enduring form the brand of weakness of Mr. Stuart's invention as a valid patent.

By way of introducing the matter generally, we may observe that, theoretically, the centre of a picture is always better illuminated than its sides, although, when only a narrow angle of view is included and a stop is used, the difference as regards equality of illumination is so slight as not to be observed. It is when very wide angles are pourtrayed that the falling off towards the margins becomes apparent. This is an invariable concomitant of the employment of a wide-angle lens when used to produce a picture of wide angle.

No lens has yet been made, or can be made, which, with an ordinary camera, can give illumination at the margin of the same intensity as at the centre; and this, for two reasons. First, the aperture of the stop, greatest when the light passes through it when placed parallel to the plate or at a right angle to the axis of the lens, is seen to become more and more oval, or lessened in its area, in proportion to the obliquity it presents to the sides of the plate; in short, less light is transmitted obliquely than centrally. And further, the sides of a plate being at a greater distance from the lens than the centre of the plate, this smaller and more attenuated beam has also farther to travel than the axial one ere it reaches its focal plane. Hence the diminution of the lighting.

This was well recognised in former times, and various schemes were suggested for equalising the lighting all over the plate. So long ago as 1863 an eminent writer on optics, the late Mr. Thos. Grubb, of the Bank of Ireland, suggested a means of doing so by the employment of an opaque diaphragm, so placed in relation to the stop of the lens as to allow full transmission of light to the margins while cutting much of it off from the centre of the picture, which is precisely what is sought to be done by the new patent. No one need to be told that, if an opaque circle be placed either outside or inside of the stop, and at a suitable distance from it, the effect will be to suppress much of the central or axial rays, while allowing free transmission to the more marginal ones. This supplies the condition for ensuring equality of illumination all over the plate.

In 1866, three years after the date previously given, this subject was brought prominently before the notice of the Edinburgh Photographic Society by Mr. George Slight, a skilful mechanical engineer, who found that all the requirements for ensuring equal horizontal lighting over the plate could be provided for by a vertical bar "at such a distance from the ordinary round stop that about one-half to two-thirds of the opening is uncovered for illuminating the extreme end of the plate, and of such a breadth as to cover from one-half to two-thirds of the opening for the centre, illuminating the centre by two equal segments of the circle, while the intermediate portions are illuminated by two varying segments, the sum of which gradually increases with the angle of inclination, until, at a point near the extremity, only one segment is employed." This subject also formed the theme for elaborate calculations by Messrs. R. H. Bow, M. Carey Lea, and others.

A method analogous to that described was published eleven years ago in the *Photographic Times* of New York, and subsequently in a treatise on the optics of photography. It consists of a small V-shaped bit of metal mounted at a short distance in front or behind the stop. As we have used this for over fifteen years, we can attest its efficiency.

We cannot imagine that the patentee of the system alluded to could have been aware of all that has been published and freely given to the public so many years since, else would he have hesitated before placing himself in an invidious position by taking a patent for it—a patent which, in the light of what we have here written, will, doubtless, not be attempted to be maintained.

THE FERROUS OXALATE DEVELOPER.

I

We are constantly in receipt of inquiries as to the best means of restoring the action of spent ferrous oxalate developing solution as well as of recovering the valuable constituents, if any, of the solution, which, though it may have ceased to be practically useful, is still far from being exhausted of its active constituents. Although the question of renovation and recovery of residues has been dealt with in our columns, it is some years ago, and since that time not only have many new recruits joined the ranks of photography, but the vast spread of enlarging and other applications of gelatino-bromide paper has caused the ferrous oxalate developer to be employed by

many more, both amateur and professional, who had not previously adopted it for negative work. There is, consequently, a large class of modern photographers to whom the repetition and extension of the information previously given may prove useful.

The ferrous oxalate developer is without doubt a comparatively expensive one unless employed under the most favourable conditions, and unfortunately those conditions are not such as prevail in the majority of cases whether amateur or professional. We assume that in this country, at least, this developer is now but little employed for negative work; hence it only comes into use when enlarging, or contact bromide prints are being worked, and this probably does not occur every day in a very large number of professional laboratories, while, so far as the amateur is concerned, the task is very likely only taken up at wide and irregular intervals.

Now, it is well known that, though the unused solution will keep fairly well, and retain its developing action if carefully stored, yet, after once using, be it only for a single development, it rapidly loses its energy, in spite of all the care that may be exercised in avoiding oxidation. This is, of course, a very annoying circumstance in cases where the work is of a fitful nature even when only small contact prints are concerned, for it practically limits the extent to which the employment over and over again can be carried, and may mean that a fresh quantity of solution has to be used for each print. If enlargements of considerable dimensions are in question, say 24 × 18, or perhaps larger, the amateur at any rate, even though he work such sizes, cannot be constantly at it, nor is it likely that the ordinary professional who does his own enlarging can be much more favourably placed; then, indeed, the costliness of this developer makes itself heavily felt, and then, if it be possible, a method of renovation, or even of recovery, of the potassic oxalate will be found valuable.

As regards renovation, we are afraid there is no really trustworthy method to be recommended, although several have been put forward, but unfortunately they are none of them to be invariably depended on. In the case of a solution that has been but little used, perhaps only for a print or two, the oldest and most theoretically correct plan in principle, heating with a little clean iron wire, will be found to answer fairly well; or the addition of a little precipitated oxalate of iron, as proposed by some, may prove of benefit, but we have not found it of much practical use. Another plan differs from these in principle, since it aims at restoring the altered or oxidised constituents of the developer instead of, as in the other cases, replenishing the active matter that has been removed. This consists in adding to the developer a solution of sulphite of soda, or, better still, of potash, which, by reducing any ferric oxalate that may have been formed by oxidation to the ferrous state, will often give a fillip to a solution that has partially or wholly lost its power. Perhaps in a combination of the two systems—replenishing as well as restoring—will be found the best result to be obtained by the process of renovation.

But these methods, or this process, unfortunately overlooks the important fact that other changes occur besides the exhaustion and the oxidation of the active developing salt, the ferrous oxalate. They have for result in the first-named methods the replacement of the iron converted into oxide by the action of development, though this is done in a more perfect manner by the iron-wire treatment than by the other. In the first the oxalic acid set free, which goes to form a double salt that will be mentioned later, attacks the metal and forms ferrous oxalate, which in turn is taken up by the oxalate of potash that has been relieved of its duty by the previous precipitation, and, so far at least as the oxalic acid and iron are concerned, matters are restored to much their original state. But the direct addition of oxalate of iron, while it restores the original activity, leaves the oxalic acid free to act as a restrainer. The treatment with a sulphite acts by removing the restraining action of the ferric salt, by reducing it to the lower state of oxidation, in which condition it again becomes active; but it does nothing to replenish the active iron actually used. From this explanation it will be seen why we urge the combination of the two systems.

But where this plan altogether fails is in overlooking the other substances that are introduced into the solution by the action of development, notably the hydrobromic acid liberated from the reduced silver in the film. The powerful restraining action of this acid, or, we should more correctly say, its *destructive* action on the image, is sufficient to account for the practical impossibility of restoring the energy of much-used solutions, since they then contain in themselves sufficient material to destroy the image formed, and so render development impossible.

Similar in its action to free hydrobromic acid, ferric oxalate behaves in a precisely like manner, destroying the image and arresting development. Hence an old developer, that has not been much used but has been allowed to become oxidised, will be found as inoperative as one that has been much used. But in this case it may be found possible to, at least partially, restore it by deoxidation. It is important to recognise the two different states of uselessness. One developer is *worked* out; the other may truly be said to have *rusted* out.

In considering the recovery of the more valuable constituents of the spent developer, we shall have to study first its chemical composition, both before and after use; but we may say a preliminary word on the advisability of this course, or rather on the question as to whether it is worth while. We may state at once our opinion that, though it may be a pretty operation on an experimental scale, it will certainly not prove a remunerative one, and that, even on a very considerable scale, it will remain to be decided whether the "game is really worth the candle." Our view is, that only by the exercise of the greatest care and the most perfect system will any pecuniary benefit be found to accrue. We shall leave our readers to judge from a perusal of the following plan, which we have found the most perfect in an experimental way.

The ferrous oxalate developer prepared in the way just recommended by Mr. M. Carey Lea and Mr. W. Willis, by dissolving precipitated ferrous oxalate in a hot saturated solution of potassic oxalate, may be looked upon practically as a solution of potassio ferrous oxalalate, a double salt represented by the formula $K_2\,Fe\,(C_2\,O_4)^2$. It may be precipitated from the solution in conjunction with two atoms of water by the addition of alcohol, forming first a deep red oily liquid, which subsequently forms into minute granular crystals of the same colour. This compound salt we may call the active developer, since, though ferrous oxalate is the actual reducer, it is *per se* insoluble, and therefore inert.

The developer, as ordinarily employed nowadays, is, however, made by mixing solutions of ferrous sulphate and potassic oxalate, the latter being in excess; this, by double decomposition, forms ferrous oxalate and potassic sulphate, the former being held in solution by the excess of potassic oxalate. This solution differs from the other by the presence of the potassic

sulphate, which acts as a restrainer. In our succeeding remarks we shall deal simply with the pure solution.

The deep red solution of potassio-ferrous oxalate is very unstable, and easily passes to a higher state of oxidation, a fact to which it mainly owes its developing power. The final change that occurs in the solution, whether by exhaustion in development or mere oxidation by keeping, is the same, except that in the former case there is the contamination of hydrobromic acid derived from the sensitive film. On this difference we shall have to remark presently. The actual change that occurs results in the precipitation of oxide of iron and the formation of another double salt, the potassio-ferric oxalate, as shown in the following equation—

$$\underset{\text{3 atoms.}}{3\,K_2\,Fe\,(C_2\,O_4)^2} + \underset{\text{1 atom.}}{O} = \underset{\text{2 atoms.}}{2\,K_2\,Fe\,(C_2\,O_4)^3} + \underset{\text{1 atom.}}{Fe\,O.}$$

Potassio-ferrous oxalate + Oxygen = Potassio-ferric oxalate + Ferrous oxide.

The oxide of iron, of course, assumes the form of hydrate and very rapidly passes to the stage of ferric oxide. The latter forms the rusty brown-red precipitate always seen more or less in old iron-developing solutions, but especially in those that have, as we described it, "rusted" out in contradistinction to being worked out by development. Probably the presence of the hydrobromic acid, derived from the sensitive film in the course of development, is the cause of the smaller precipitate of oxide in that case.

The potassio-ferric oxalate differs very considerably from the salt of lower oxidation, having the form of handsome flat crystals of a brilliant emerald green colour, and of a much lower degree of solubility than the ferrous salt, in consequence of which they crystallise out of the old developers, and form the well-known green crystals that form, with the oxide of iron, the deposit in such solutions. Of these crystals we shall have more to say, in dealing with the process of recovery, in another article.

PHOTOGRAVURE.

The paper on the above subject that was read at a meeting of the Photographic Society of Great Britain a short time back has now been published, and will be found on page 523. At the meeting at which it was read disappointment was felt by some that the author, who is a practical photographic engraver, did not give any working details of the different processes to which reference was made. However, the paper is one that will be perused with interest by many of our readers who are interested in the subject. At the conclusion of the paper, however, upon the suggestion of the chairman, allusion was made, in outline, to some of the methods in daily use.

Photogravure may be classed under two heads: One, the etching method, by which the intaglio image is obtained by biting into the metal, usually copper, with an agent that is capable of dissolving that metal; the other, by forming the plate by depositing copper, by electrolysis, on an image in relief in gelatine. Both systems are capable of producing excellent results, and neither of them is complex in its manipulations. It is to remarks on the latter method that we shall here confine ourselves.

If a piece of carbon tissue be exposed behind an ordinary negative, and is then developed on a rigid support, such as a glass or a metal plate, we obtain a gelatine image in relief. The relief will be highest in the deepest shadows, and lowest in the high lights. With the proper exposure and development there will be no gelatine at all on the extreme high lights, and the gradation between them and the deepest shadows will be perfect. Now, if an electrotype be made of this relief, we get an intaglio image in copper; but, if we attempt to print from it, after the manner of copper-plate printing, we shall fail, as the ink will wipe out during the operation, owing to the smooth surface of the image having no ink-holding properties. A good printing plate, it may at once be explained, must not only have the image in intaglio, but it must also possess granularity, and the sharper that is the better will be the plate. Not only must the image be grained, but it must possess a stronger and a more pronounced grain in the deepest shadows than it does in the middle tints, while the extreme high lights must be represented by perfectly smooth metal, with no grain whatever. In fact, the finished photogravure plate may be considered as analogous to a mezzotint plate.

It may be well to explain here, for the benefit of those who are not familiar with the work, what a mezzotint plate is. Mezzotint engraving is done as follows: A plain plate of copper has its surface evenly roughened all over, except the margins, by working over in every direction with a steel tool having a sharp serrated surface called a "rocker" or "rocking tool." This treatment not only indents the surface of the copper, but at the same time raises a "burr." If the plate, at this stage, be inked in and printed from, as is done in copper-plate printing, it will yield an impression of intense blackness, and, if the work has been skilfully performed, perfectly uniform all over. On this rough surface the engraver forms his picture by scraping and burnishing away more or less of the burr and granularity from certain portions and leaving it on others. In the finished mezzotint plate the deepest shadows are represented by the work as left by the rocker, while the half-tones and lights are modifications by the scraper and burnisher. The closer a photogravure plate can be made to resemble a mezzotint one, the better will be the prints it will yield.

There are two systems by which a grain may be imparted to the gelatine relief. They may practically be classed as the chemical method and the mechanical method. The former, of which the Pretsch process may be taken as a type, consists in producing a reticulation of the gelatine film similar to that in the collotype process. By this means a discriminating grain is obtained which is coarsest in the shadows, is finer in the middle tones, and is absent, or nearly so, in the lights. The working of this process is, to a great extent, dependent upon the character of the gelatine used and the temperature at which the film is prepared. Some years ago Colonel Waterhouse published a method of producing a reticulated grain similar to that of Pretsch, but by an after-treatment. A carbon print, after it had been developed on a copper plate, was treated with an alcoholic solution of tannin. But here temperature, as well as the gelatine used for the carbon tissue, were in practice, found to be important factors in the process. Although the grain obtained by reticulation is a discriminating one, it is scarcely such an ink-holding one as is desirable, inasmuch as its edges are somewhat rounded and quite unlike the sharp grain or burr of a mezzotint.

Mechanical grain may be obtained in several ways. Goupil's method is asserted to be by using a "carbon" tissue containing a gritty matter. This gritty matter is said by some to be soluble, by others insoluble. But the details of their process, whatever it may be, like many others that are worked commercially, are preserved as a secret; therefore this statement may well be received with doubt. Printing through a grained

screen has been adopted; but it is seldom used for intaglio work, though it is largely so for relief.

Perhaps one of the best methods of producing a mechanical grain that has yet been published is that of Colonel Waterhouse. It is what is generally known as the Waterhouse process. This grain has the advantage of being a discriminating one, inasmuch as it is deepest in the deepest shadows, more or less shallow in the lighter tones, and absent in the highest light. The process also possesses the advantage of being simple in its manipulations, as the following brief description will show: A carbon print from a negative, after it has been developed on a copper plate, while still wet, is dusted over with fine sand or powdered glass. This sinks into the tender "jellied" film in proportion to its thickness, and, as the film dries and contracts, it seems to draw the sand still deeper into the film, and thus makes the grain sharper and more pronounced. When dry, the sand is brushed out or otherwise removed. Of course, if ordinary sand were used, it would adhere permanently to the film. But, in order to avoid this, Colonel Waterhouse adopted the happy expedient of previously treating the sand with stearine or wax; it could then be removed with comparative ease.

A modified method of working the Waterhouse process was introduced by Mr. E. W. Foxlee. Instead of using waxed sand or glass, powdered resins are substituted. Then, instead of removing the particles by mechanical means, they are simply dissolved out by a solvent of the particular resin employed. The advantage claimed for this modification is that, as the granulating substance is removed by solution, there is no danger of injuring the grain by friction, which is liable to be the case if the sand has been but slightly waxed. Again, when the sand has been sufficiently waxed to permit of its easy removal, the sharpness of its facets is in a measure destroyed. It can readily be conceived that by this method a crisper and better ink-holding grain may be obtained than with the waxed sand.

When once a gelatine relief with a discriminating grain of the right character is obtained, the production of a printing-plate from it becomes an easy matter by the electrotype process.

Tele-photography.—We are informed that the firm of Carl Zeiss, of Jena, are about to construct a simple combination to use along with their anastigmatic lenses for tele-photographic purposes, and they expect to furnish them in a few weeks.

The New Honorary Secretary of the Photographers' Benevolent Association. — We learn that Mr. H. Snowden Ward has undertaken the office of Honorary Secretary to the Benevolent Association. The fact of Mr. Ward being in constant touch with all classes of those connected with photography should be of great value to the Association.

Colour Sensitisers.—Those of our readers who would wish to possess such a knowledge of the various coal-tar colours manufactured in the past and the present as will enable them to master the intricacies of the eosine question, and become acquainted with the names of all the dyes that might be used in connexion with processes for making colour-sensitive plates, will find a mine of information in a new work recently published in Germany, *Tabellarische Uebersicht der Künstlichen Organischen Farbstoffe*, by Von Gustav Schultz and Paul Julius, writers well known to fame in this particular department. The work is, in effect, a tabulated catalogue of all past and present coal-tar colours, with complete references to existing literature on the subject.

Hand Cameras.—A correspondent inquires if we can give him any idea of the cause appearing to operate in reducing the number of detective cameras to be seen this year at seaside resorts. As to the fact that this decadence of the use of the instruments really exists, he states that he entertains no doubt. We can only say that it can scarcely be possible for us to give an explanation, if even the state of the case be correctly reported; but it is quite possible his may be simply a particular experience, conditioned by locality, weather, or chance coincidence. But, at the same time, we may be permitted to say that the sooner the name "detective camera" is given up the better for the status of photography. Numberless workers, who are gentlemen and ladies in the true sense of the term, use the instrument for pictorial purposes alone, but no terms can well be too strong to characterise the conduct of those whose aim is mainly not the production of pictorial records or pretty spontaneous grouping of figures with outdoor accessories and surroundings, but simply to minister to a low form of curiosity and to intrude upon privacy in a manner which is properly characterised as impertinent. We have heard of more than one case where the offending "cameraist" has met with his deserts with an argument straight from the shoulder of an indignant friend, while the offending instrument has been put ruthlessly out of court in a manner as effectual as violent.

Action of Water upon Glass.—Messrs. F. Mylius and F. Foerster have recently been making some researches into the action of water upon glass, from which they have drawn the following propositions, which they consider proved by their own observations and those of other experimentalists:—The solution of glass in water depends on a decomposition in which, in the first place, free alkali appears. The silica of the glass is secondarily dissolved by the free alkali. The constituents of the solution vary according to the conditions of digestion. The quantity of alkali which passes into solution from a given surface under given conditions is a measure for the attackability of the glass under these conditions. The attackability of surfaces of glass by cold water decreases at first very rapidly with the duration of digestion, and subsequently approach constant values. Different sorts of glass display a different persistence of the solution. The attackability of glass increases very rapidly with a rising temperature. The relation of the attackabilities of different kinds of glass depends on temperature. From glasses of equal attackability unequal weights may pass into solution. The attackability of good glass is decidedly decreased by a previous treatment with water. The worse a glass, the less its attackability is diminished by treatment with water. The attackability of glass surfaces is modified by "weathering." After treatment with water, surfaces of glass have the property of taking up alkali from the solutions which have been formed, and of giving it up again on renewed treatment with water. Potash glasses are much more soluble than soda glasses, but the differences disappear in proportion as the glass is richer in lime. In the substance of glass vessels, which are not readily attacked by cold and hot water, the lime, alkalies, and silica must bear a certain proportion to each other. Among the best known glasses plumbiferous flint glass is least soluble in water, but it is corroded at its surface and easily decomposed by acids.

The British Association.—The great event in the world of popular science at present is, as scarcely need be said, the meeting of the British Association, who meet in the same city that so hospitably entertained photographers in conference a short time before. In the address to the Chemical Section by its President, Professor Herbert McLeod, there occurs a portion which, in its possible application to the elucidation of photographic questions, may well be here quoted. Speaking of so-called catalysis, instances of which are so rapidly being explained away that he thinks the time may not be far distant when the term will be banished, he writes upon the influence of a small quantity of one substance upon interactions of large quantities of other substances, in which its action is explained as being catalytic, and says: "We have now many instances of the influence which small quantities of substances have upon chemical reactions. These influences may be more common than is generally supposed. The presence of a third body is frequently help-

ful in the combination of the elements with one another: thus, dry chlorine will not attack melted sodium or finely divided copper; an electric spark will not cause a dry mixture of carbonic oxide and oxygen to explode; carbon, phosphorus, and sulphur will not unite with dry oxygen; and, as chemical science progresses, we may find that many well-known actions are conditioned by the presence of minute traces of other matter which have hitherto escaped detection. We all know the profound alterations in the property of substances by minute traces of impurities: less than one-tenth per cent. of phosphorus will render steel unfit for certain purposes. The sapphire and ruby only differ from colourless alumina by the presence of traces of impurities hardly recognisable by chemical analysis. During this meeting we hope to have a contribution to the section on the influence of what may be called impurities in the properties of different substances and their influence on chemical manufacture." Now, we do not hesitate to say that photographic processes and the production of photographic materials, as all old wet-plate workers can better than any expound, offer examples far more critical, and involving quantities of far minuter proportions, than those indicated in the portion of Professor McLeod's address we have just quoted, and it is possible that light thrown upon this dark place of science may also illuminate equally obscure places in our particular branch of science.

Lightning Photographs.—In the current number of *Knowledge* there is a reproduction of a photograph of lightning, taken by Mr. F. H. Glew, of Clapham, by which the latter gentleman claims to have measured the duration of the flash. Mr. Glew has favoured us with a print from the negative, which delineates the ribbons of the main flash with remarkable distinctness. Mr. Glew supplies our contemporary with the following interesting details:—"The photograph was taken about 9.50 p.m., on Tuesday, June 28, 1892. The camera was pointed S.E. from the door, at 156 Clapham-road. The lens was secured to the hammer of an electric bell, giving nine complete vibrations per second, the amplitude being about ½ of an inch. It is evident that the main flash and its side forks all took place in less than the half of one vibration, and the motion of the lens separated the three component flashes, which to the eye would have appeared to be superposed. I compute from measurements that the whole discharge occupied about the one-twentieth part of a second, and the interval between the components about one-fortieth of a second. It will be seen that the right-hand side of each spark is fainter than the left, showing that the duration of each component was considerable, and not of the same intensity throughout its existence. The original negative shows this a little clearer than the print. Thomas's 'Sandell' plates were used, which, being thickly coated, in separate layers, prevented halation defects. Some of the shadows of chimney-pots are due to sheet lightning previous to the grand flash. The vibrations of the lens were in the same plane as the plate, and in the direction of its length. It will be seen that one portion of the flash is converted into chain lightning, this being due to the motion of the lens being almost in the direction of the length of this part of the flash, and in consequence of this the different curves have been more or less superposed in direction of length, in the form of a chain. I think this throws some light on the so-called chain lightning as seen by the eye, for, if the duration of a compound spark is so much as one-twentieth of a second, it is possible for the eye (corresponding to the lens of the camera) to move through a certain distance, and, if this movement of the eye opens to be in the direction of the length of the compound spark, then its components will be drawn out into a chain-like structure or complex ripple. Perhaps the duration may be even greater than one-twentieth of a second in some cases, and the eye may be set in motion by the first component of the flash. As the tendency of the eye would be to move in order to bring the object into the best position for distinct vision, so I think the effect of chain lightning might be formed in this way, or by accidental motion of the eye of the observer during the display."

AMIDOL—A NEW DEVELOPER.

Three months since we directed attention to the announcement of the discovery of a new substance—amidol—which was said to possess the remarkable property, when simply dissolved in aqueous sodium sulphite, of acting as a developer of the latent photographic image without the addition of an alkali. Messrs. Fuerst Bros., of 17, Philpot-lane, the London agents, have now placed at our disposal for trial a sample of the new reagent, which has been favourably reported on by Eder, Vogel, Stolze, Just, and other able experimentalists.

Chemically regarded, amidol is expressed by the formula

$$C^6H^3\begin{cases} O\,H \\ N\,H^2 \end{cases}2.$$

In appearance it is a grey, finely powdered body, not unlike powdered magnesium, freely soluble in water, and apparently unaltered by two or three hours' exposure to the air. The following are the recommended proportions of the stock solution which we made up:—

Amidol	20 parts.
Sodium sulphite	200 „
Water	1000 „

This forms a solution at a convenient degree of concentration, and, moreover, one that is colourless. In using the developer we diluted one part with five times its volume of water; but so rapid was its action, even with the addition of a grain of potassium bromide to the ounce, that we were compelled to still further dilute it down to 1:8. It is evidently a most energetic developer, particularly, as we practically observed, in cases of under-exposure, and yields negatives having all the necessary density and detail in a surprisingly short time. A further point in its favour is that it works cleanly, develops several plates successively with apparently undiminished rapidity of action, and does not appreciably change colour while in use. Its freedom from staining points to its utility for glass and paper positive work.

Amidol is decidedly a novelty in developers, and we hope to take a further opportunity of experimentally examining its properties and of stating them to our readers.

CONVENTION JOTTINGS.—III.

At Newhaven.—To lengthen the days that were all too short, some of us went down to the quaint old fishing village, Newhaven, in the mornings, where many picturesque studies were to be found, and not the least enjoyable feature of the visit, the fish breakfast supplied at the hotel, which is famed for its service in this way, some seven or eight courses of fish being served, and all most delicious and appetising, a most enjoyable finish to our morning's work. The Newhaven fishwife was rather a puzzler to some of our southern friends. One of them, wishing to have some fun with one of these sturdy maidens of the sea in the midst of his chaff, did not get the best of it, when, with a broad laugh, the fishwife exclaimed, 'Wha cau'd ye partin face, my lamb?' and, in answer to some other pleasantry of the youth's, she said, "Na, na, my man! y'er no gaun tai get a groat haddie for fourpence here!" Our friend gave it up in despair, he thought the woman was speaking in a foreign tongue. One of our party, who was going round with his camera catching up little bits here and there, was advised by an old fisherman not to be blowing up the harbour with his infernal machine.

The Land of Scott.—Unable, as we said, to form one of the Melrose excursion party, and enquiring of a friend who attended that excursion, he says:—"The day at Melrose was very dull, and, after taking one or two pictures, we thought we would like to go over and see Abbotsford, which did not happen to be in the day's programme. So we drove over, only to find that we were not allowed to photograph there; and, to get a picture of the house, with the river in front, we would have to travel round some five miles. We, however got a pitch outside the grounds which gave us a fair view of the house, and we managed to get a negative. On the way we took up two American ladies who were out touring. They told us confidentially that they had struck up a wrong day for Melrose, as they really could not see anything for photographers—swarming in every corner all over the place with their cameras—and that they had left the Abbey in disgust. At Melrose many of our company stuck close to the conductor, Mr. Hippolyte Blanc, who covered the ground, staying at interesting points, learnedly discoursing on the

architecture and history of Melrose and Dryburgh Abbeys; so that many who did not find the weather bright enough to continue taking pictures on plates found pleasure in listening to his sermons from stones."

Roslin.—We thought it rather strange when the announcement was made regarding the Roslin Chapel trip, to be informed, "But you are not to be allowed to photograph in the chapel." It seemed slightly out of place for the Convention to make a trip to a place where they were debarred from photographing the chief point of interest, but it seems the right has been sold to some large photographer, hence the reason. But, at such a time and for such a purpose, we think the right might have been waived for one day.

There must be a Mistake somewhere.—We overheard the following conversation: "Oh, Mr. Cembrano, you might sing us a song." "Oh, dear no, I never sing." "That's not so, you know. When at St. Andrews I heard you singing to yourself." "At St. Andrews," the youth replied, thoughtfully, "Surely never, I was not so bad as that! Oh, no, it couldn't be! that was the day I was drinking water." "Drinking water! what do you mean?" "Well, you see, Warnerke was telling me that he could photograph for a whole day and drink nothing stronger than water. I wanted to show him I could do it also. So I drank nothing that day but water. I could not sing on water, you know; there must be a mistake somewhere."

Does the Cap Fit?—When at St. Andrews we overheard a conversation that led us to consider that our worthy president posed as an impressionist of the first water. He was telling how, in the hurry, he had left part of his apparatus at home, and so was unable to photograph. We were wondering what part of his kit it could be that had been forgotten that rendered the impossibility to make pictures; but, seeing that the only part of his set that he had brought was the cap of the lens, we quite understood why he could not take even a pinhole picture. But the impression he left upon us was, that under the circumstances he looked himself a very pleasant picture.

By Road and Rail.—We were rather astonished to see one of our members (Anckorn) careering through the streets of St. Andrews on a bicycle, and more astonished when he told us that he had come all the way from Edinburgh on it, and further, that he was going right on to Arbroath (we think he said) that night. He was quite fresh and lively, and looked as if he enjoyed it. The train was good enough for the rest of us.

They didn't see the Point.—"What's the use of telling you a good thing?" said a humourist, at a post-Convention meeting, after giving a story that fell flat. "You never see the point!" "Never see the point!" exclaimed Mr. Bothamley, "and here have I been leading off the laugh at everything you've said to-day; you are ungrateful, sir. I must go work for other chestnuts."

On the "Columba."—It seemed as if many of the members of the Convention had found Scotland a pleasant country, as we found them in detachments for days after wandering up and down all over the place. Some days after Convention we found a contingent of them on board the *Columba*, and it would have done Mr. Hastings' heart good just to have got one good snap-shot at Mr. Kidd and Mr. Cembrano as they stood at the stern of the vessel, inducing the sea gulls to hover near by filling the foaming main with broken biscuits. We wonder how these bird pictures turned out. Mr. Seaman was on board the same day, and, getting on the right side of the captain, he was allowed on the bridge to photograph; he was so excited over his success in this matter, that he made, he said, four exposures without drawing his shutter once. Of course, that was a waste of time more than a waste of plates.

The Cramond Trip.—We got rather mixed at the Cramond excursion, although it turned out one of the most enjoyable of days. We undertook rather too much for one day, and the party got broken up, which did not help things. Some were taken to the village of Cramond, and some to the bridge; and by the time they met each other and had lunch the day was too far gone to get to Dalmeny and the Forth Bridge. We came quietly home, but a few of the party voted for the Forth Bridge and others for Dalmeny, which feat they accomplished; but it pressed them rather hard to be back in time for the Convention dinner. The open-air lunch at *this* outing was very enjoyable.

Snap-shots.—We have always been of opinion that snap-shot pictures, to be successful, require some little education, and that pressing the button is not a guarantee for a picture in all cases. We have had word from one or two of our friends, who promised to send us on pictures (if right) in which we took some interest, and in most cases failures from short exposures, too much stopped down, &c., &c., proving to us that the matter in hand has not had study enough. One of the best hand-camera workers we know was saying at the Convention that at the beginning of each season he works out his distances, say, six, eight, ten, or twelve feet, and practises on them till he is quite sure that he can judge correctly, and then he feels right for the season; and we feel that, if this is necessary for distance, so is it necessary for "time" and "stop" before the operator can fire away successfully.

REPORT OF THE DELEGATES OF THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION TO THE EDINBURGH CONVENTION OF 1892.

"Big Ben" was booming twelve when the tender conveying one of your delegates left the Westminster pier *en route* to the good ship *Seamew*, picking up on the way delegates from other societies. Your other delegate was found already on the *Seamew*, completing various arrangements made for the comfort of our party, which numbered ten, ladies and gentlemen. Off Greenwich we discerned friend Haddon quietly taking a shot at our passing vessel. We gave him a hearty cheer, regretting at the same time that he was not with us.

Time on shipboard passed pleasantly; what with deck quoits, cards, and discussions as to developers, especially the new one, "Rodinal," the spirited representative of which popular combination was one of our party. Indeed, so deeply were its merits discussed, that the very engines we fancied, seemed to say "Rod-i-nal, Rod-i-nal, Rod-i-nal," in their revolutions.

Many groups on board were taken; the captain himself, seeming to be rather fond of the operation, was posed several times. He also kindly "slowed down" when passing the "Bass Rock," and sounded the steam whistle, causing the gulls in thousands to fly off the rock, making a very fine picture.

At all times a gay and beautiful city, Edinburgh was certainly looking its best as your delegates approached its ancient port, and continued to do so, without a break, during the continuance of their stay.

At seven o'clock on Monday evening we assembled in large numbers to be welcomed by the Lord Provost, who, in the course of his remarks to us, referred in a most able manner to the great strides photography has made in recent years. He was followed by Mr. C. H. Bothamley, who, in the absence through illness of our retiring President, Mr. W. Bedford, introduced our new President, Mr. Georgs Davison, whose exhaustive address, coupled with his genial manner, was much appreciated by every one present.

Our first excursion, which was to Melrose and Dryburgh on Tuesday, under the leadership of Mr. Blanc, was most successful, particularly for the stand cameras, subjects being mostly of an architectural nature, and the light not being particularly good, it was not so favourable for the large contingent of hand-camera men, and so (and here let a mild protest be put in) they accordingly amused themselves by taking shots at unoffending groups of their fellow-pilgrims.

The drive from Melrose to Dryburgh, through the charming Lowland scenery, was most enjoyable, and a thing to be remembered. Our leader, Mr. Blanc, was most assiduous in pointing out the various beauties of the architecture, and coaching us well up as to the historical associations of both Melrose and Dryburgh. The post-Convention meetings on Monday and Tuesday evening were held in a large room in the Royal Hotel, kindly placed at our disposal by your popular member, Mr. H. M. Smith. Here toast and song, interspersed with anecdote, prevailed till the small hours, then came changing plates, and many and amusing experiences

could be related, particularly about the member who always backed his plates in his bedroom, in a very dim light, and found in the morning, on waking, that his night shirt, face and neck, to say nothing of the sheets and pillow-cases, had all been liberally treated with the same excellent mixture. "Whisky" was suggested as a possible cause, but the effect was not generally admired. After two or three performances of that nature, added to which, in some instances (when very bad), was the labour of washing the stains out, before leaving the bedroom, that member omitted to back any more plates.

On Wednesday morning a large party of hand-camera men, headed by "Poor little Mr. Brown," started off very early for Newhaven, to take "Fish Wives," and partake of "Fish Breakfasts;" both objects were satisfactorily attained, one gentleman owning to having exposed 24 plates within an hour on the former characteristic subjects; indeed, in such a pursuit, it is surprising what early risers photographic enthusiasts can be, notwithstanding the special licence granted by the Lord Provost and magistrates for the prolongation of our post-Convention conviviality at Daish's, and doubtless many characteristic pictures of Scottish fisher folk have enriched the collections of the number of hand-camera men who were "up in the morning early."

At the annual meeting at ten, it was decided to hold the next Convention at Plymouth, in 1893. The Council was duly elected, and then all adjourned to Princes Gardens, where Mr. Alexander Ayton had selected a splendid background of the Castle Rocks; with the assistance in grouping of our member, Mr. F. A. Bridge, a very fine picture resulted. A large battery of other cameras was also directed at the group, and we may hope to see results of all those other exposures in due time.

In the afternoon, a paper by Mr. H. P. Robinson, entitled "Individuality in Photography," was read by Mr. Hepworth. Another paper on "Photography in Relation to Painting," by Mr. Arthur Burchett, was read by Mr. C. H. Bothamley, in discussion on which Dr. Mitchell, of Philadelphia, alluded to quick exposures representing objects as the eye did not see them, the image on the retina never being shorter than one-tenth of a second, in proof of which he cited Professor Muybridge's pictures, as being so unlike what the eye really catches.

The President referred to Mr. Burchett's use of coloured glass with the camera when making exposures.

Miss Catharine Weed Barnes then read her paper on "Amateur Photography in America;" she alluded to the fact that far too many workers there, as here, begin and end with detective cameras, they procure one expecting that it will do every kind of work, and very naturally soon get disgusted; no one could appreciate photography at its full value till they had realised all the possibilities of time exposures. Miss Barnes also alluded to American workers not giving enough consideration in choosing a subject and to the poverty of her country in historical objects; she did not consider the clear atmosphere of America was so well adapted for general landscape work as the always blamed English sample, and claimed that American-made cameras were far more suitable than those of English make for use in her country; they were lighter, had more improvements, the plate-holders also were more compact and lighter. American sizes in both negative and lantern plates were the best. She also alluded to a violet-coloured lens for the truer rendering of half-tones to be used in place of the back combination of a rapid rectilinear lens, giving, with portraits especially, a remarkably improved effect.

In the discussion which followed, Mr. H. Sturmey said no doubt America was far ahead of England in the use of photography in certain studies, and for book illustrations, but he could not agree with Miss Barnes as to the superiority of American cameras, and the American slides might be lighter, but they were quite as bulky.

Mr. Howard Farmer's paper on the "Deficiencies in the Training of Photographers" was read by Mr. Cembrano. It treated the subject very cleverly from nearly every standpoint, and caused a large amount of discussion.

Mr. George Mason stated that, as to the limited supply of good assistants, the matter rested with the assistants themselves; so few tried to make themselves all-round men, contenting themselves with perhaps one branch, and even the use of one maker's lenses.

Mr. Bothamley then, by desire, opened a discussion on development. He stated that he had not found much difference in results between pyro and hydroquinone, and had not yet been able to find out any great superiority of pyro and soda over pyro and ammonia, or *vice versâ*. He questioned whether the greater softness in negatives claimed by the users of ammonia would not be due to general fog. He could not agree altogether with Messrs. Hurter & Driffield's theories, as he thought that the experiences of distinguished workers should be taken into account; if Messrs. Hurter & Driffield were right, then nearly everybody else was wrong.

On Thursday evening, Dr. Mitchell, of Philadelphia, gave us a most interesting paper on the "Colour Screen in Landscape Photography," which he considered indispensable for its power of materially lessening the difficulty of obtaining even and harmonious exposures; for both foreground and extreme distance he described a very simple way in which he prepared his own screens, and spoke highly of the great comfort in using celluloid films when on a tour, also remarked on the necessity of giving full exposures when using "ortho" films, stating that they would bear an amount of over-exposure which would be ruinous to ordinary plates.

In the discussion that followed Mr. Bothamley stated that he agreed with Dr. Mitchell that if was possible to overdo the yellow screen, and so yet a worse result than an ordinary plate would show; but he did not agree as to the necessity for such lengthened exposures. He had used "ortho" plates for shutter work with great success, using from *f*-8 to *f*-16.

Mr. Weir Brown said that pictures taken late in the day with ortho plates showed great advantages over ordinary plates. He found that, using them then, without the screen, they were one-half quicker than ordinary plates.

The President wondered why they were not more used than they were, for it was a fact that they were, comparatively speaking, very little used. He accounted for it, to some extent, by the different conditions under which they had to be worked, both in the field and dark room.

On Thursday morning the greater number of us went to St. Andrew's, and an enormous number of plates were exposed on the cathedral ruins, the old castle, and the beach and harbour, and the fine golf links. We were blessed with splendid weather, and it was acknowledged that the Edinburgh Committee, in selecting such interesting places for the outings, deserved the most unqualified praise. Some complained of the long distances that had to be traversed by rail; but the heated political discussion that generally arose, owing to the great victories the Gladstonians were gaining every day, seemed to make the train journeys less irksome, if sometimes they were rather noisy.

On Friday your delegates went to Cramond Bridge, securing some fine views there and along the river Almond, and in the evening the annual dinner was held at the Waterloo Hotel. It was attended by a very large number, the presence of ladies, for the first time, giving the banquet a most enjoyable appearance. Many were the toasts, and deep was the regret expressed that some of our most popular members had been unable to attend the Edinburgh meeting. The musical arrangements were under the management of Mr. George Mason, who eclipsed himself, and induced a number of ladies and gentlemen to entertain us by song and recitation.

On Saturday morning, at ten, the Council Meeting was held. Mr. George Mason, of Glasgow, was elected President of the next Convention, to be held at Plymouth; the accounts were passed, showing a balance to the good; and so ended the most pleasant and successful Convention meeting up to date.

It was very gratifying to your delegates to observe that at all the outings, and meetings, and dinner there were more members of the London and Provincial present than of any other Society, not even excepting the local (Edinburgh) Society), whom we must take this opportunity of thanking for the great trouble they had been put to in arranging all the excursions, luncheons, &c. To Mr. Blanc, the President, and Mr. Barclay, the Hon. Secretary, great praise is due, and also to many other Edinburgh gentlemen, who laid themselves out to amuse and entertain us; indeed, nothing was wanting on the part of the Local Committee to make the meeting what it has been—"a thorough success."

"Auld Reekie" has seldom been seen to better advantage, and the Clerk of the Weather was decidedly on his good behaviour.

On Saturday morning we all dispersed, many going north, amongst others your delegates, who went, *viâ* Callender, to spend a pleasant time at the Trossachs, then through Loch Katrine and Loch Lomond to Helensburgh, on the Clyde, and sailing down the estuary of the Clyde to the Isle of Arran, where more plates were exposed, and your delegates parted, one coming home by the west coast, and making a pleasant little jaunt into Tipperary, thence home *viâ* Southampton and Dover, having had a very enjoyable time on the water; the other delegate returning shortly after by the east-coast steamer.

R. P. Dradge.
J. Weir Brown.

JOTTINGS.

If Mr. Timothy Healy, M.P., and his friends have their way in the Parliament just opened, it may be necessary for the Photographic Convention of the United Kingdom to somewhat modify its title before

the Dublin meeting of 1894, since, in the event of the passage of a Home Rule Bill, the Kingdom will no longer be "United." Writing of the Convention, I am glad the Editor is to give us a reproduction of Mr. Ayton's group. If the print is up to the quality of last year's, everybody will be satisfied. In a picture of the group which one of your contemporaries gave its readers a few weeks ago, "Cosmos" comes out so badly that neither he nor his wife can trace any resemblance to himself in the figure which is meant for him. Please therefore, Mr. Editor, let that part of the picture in which I have a place be nicely printed, so that the partner of my joys and sorrows will be able to recognise me, and thus have to withdraw her furtive hints as to my having gone to Paris instead of to Edinburgh!

Although the term "detective camera" as applied to what is now generally called the hand camera, has fallen into almost complete desuetude, there was a degree of fitness and applicability about the original title which, in my opinion, so forcibly indicated the uses, or rather the abuses, to which it is too frequently put, that on the grounds of correctness of description I am sorry for the change. An unchartered private detective, such as Divorce Court and other cases limn for the public gaze, is a low, despicable being, and I have no higher opinion of the photographer who employs his "detective" or "hand" camera for a parallel purpose—that is, for securing records of the doings of persons in strange, unusual, and, perhaps, apparently compromising situations. I am glad to perceive that the editor rebukes a hand-camera correspondent for having photographed a group of men in a condition of semi-inebriety. Such a proceeding is, to say the least of it, uncharitable and impertinent. It is because I frequently see hand-camera pictures, which are undoubted outrages upon the privacy and freedom of movement of the individual, that I venture to protest against the impudent, thoughtless, and indiscriminate purposes for which the hand camera is so often employed. As a matter of strict right, I consider one person absolutely disentitled to photograph another without the latter's permission; but, when it comes to "snap-shotting" him under ludicrous, uncommon, or equivocal conditions, the hand camera is simply converted into an instrument of backbiting and scandal-mongering proclivities. So order, gentlemen, please!

What a lot of prizes that mysterious body the Amateur Photographic Association gives for competition among its members! I think I shall join it—for, to judge by the report published in your last number nearly, if not every, competing member secures a prize. I observe that Mr. W. Jerome Harrison was elected a member on July 27, and awarded a prize the same evening. How nice! I wonder what "Talbot Archer" will have to say of the Amateur Photographic Association, presided over by his Serene Highness of Teck, in the next number of *Anthony?* Something pretty, I'll be bound.

That negatives actually, as well as apparently, lose density in fixing is a contention both unsound in theory and not borne out in practice. The eyes of individuals are, doubtless, occasionally deceived over the matter, and so the conclusion is come to that some makers' plates "lose" more in the fixing than others (*vide* Mr. Albert Levy). Possibly; but to generalise that loss of density in fixing is therefore a common phenomenon is a fallacy. Mr. John Sterry's proposed method of ascertaining to what extent reduction would be likely to take place during the short time required for fixing negatives, by immersing plates of known densities in hypo for a given time, and then measuring the densities after immersion, is an admirable one; but why did Mr. Sterry keep his plates in the baths sixty and forty-eight hours respectively, and from the results conclude that the loss of density in half an hour must be slight; why not try the experiment for the average length of time fixation occupies, say a quarter of an hour? Nobody in his senses leaves a negative for sixty or forty-eight hours in hypo.

I see that, at a meeting of the Brixton and Camera Club the other night, the following question was asked: "For sea pictures, is it advisable to use a quick plate and a small stop, or a slow plate and a large stop?" and that "the meeting 'seemed' to favour the latter view." I should like to know on what grounds, and why the comparison was confined to sea pictures. Those gentlemen who preferred the slow plate and the large stop must have forgotten to bear in mind that, if the rapidity in both cases were equalised by the enlargement of the lens aperture employed with the slow plate, a quite different kind of image as regards definition would be obtained. I assume *f*-11·3 and *f*-45·2 as being the large and small stops respectively, which would mean that the rapid plate would require to be sixteen times quicker than the slow plate. COSMOS.

THE INACCURACY OF DESCRIPTION OF PHOTOGRAPHIC OBJECTIVES BY MANUFACTURERS AND EDITORS.

[American Journal of Photography.]

BARRING the last two words, the above is the title of a paper by Mr. W. A. Cheyney that particularly attracted my notice in your issue for April. The paper is to the point, and is on a subject that ought to be thoroughly ventilated.

OPTICIANS AT FAULT.

Put briefly, the matter is this. A number of opticians make lenses especially for photographic use. Many of these lenses are, considering the conflicting requirements of a photographic lens, so good that they are a standing wonder. The opticians charge a pretty stiff price for them, but of that we, the buying public, do not complain. We ask, however, if it is not unreasonable to demand, that the descriptions of these lenses, in catalogues and advertisements, be at least fairly accurate, that they be not disfigured by a lack of intelligence that would bring ridicule on the advertisement of a tailor or shoemaker.

It is probable that the catalogues and advertisements of most manufacturers of photographic lenses are a relic of the time when the greater number of photographers were ignorant of the most rudimentary facts, not only of optics, but even of the properties of the lenses they used; when anything about the ratio of aperture to focal length was a mystery profound, when it was commonly supposed that there was some fetish in a "portrait lens," apart from the angular aperture, making it particularly suitable for portraiture; when, particularly, there were wonderful delusions about depth of focus, when, in fact, it would have been useless to afford the information now so generally demanded.

There are exceptions to every rule, and there are some (English, at any rate) opticians who issue catalogues giving all the information wanted. I think of one in particular who sends out a large sheet giving the equivalent focus and the maximum working apertures of all the different sizes of the different classes of lenses that he makes. I know, too, that with this optician the actual equivalent focus is always very nearly that stated in the sheet, that the apertures are actually those stated, and I believe that, if a lens of precisely the focus mentioned is wanted, the fact has only to be stated.

How different it is with many opticians was forcibly brought to my attention a little time ago. My advice was asked about buying lenses for a particular kind of work. I soon decided on the class of lens wanted, but it was necessary to determine from whom the lenses should be ordered, and hence a great rummaging through catalogues. It was quite essential to know the equivalent focus and also the maximum working aperture before ordering the lenses. Now, in the catalogues of three English opticians of high repute, there were found the following anomalies. One gave, throughout, the equivalent focus of the lenses, but nowhere stated the working aperture. Another gave the equivalent focus of the lenses and their diameters, accompanied by diagrams showing that the working aperture was in most cases much less than the diameters of the actual combinations. In the catalogue of still a third optician, there were given, for some lenses, both the equivalent and the back focus (almost a work of supererogation), for others the equivalent focus only (just what was wanted), for still others, merely the focus. In this last case, it was only actual experience of the lenses that enabled me to know that it was the back focus that was stated. It is some slight consolation to think that these opticians lost all chance of at least one order, simply from the idiotic way in which their catalogues were put together.

There are other offences committed by manufacturers of lenses. Why, for example, should the intelligence of the photographic public be insulted by advertisements of wide-angle lenses headed, "These lenses include an angle of more than 100°," whilst below there is a table of the sizes of plates that the lenses will cover with "large, medium, and small stop," which table shows that the lenses will not include an angle approaching 100° even with the small stop, and taking the diagonal of the plate into consideration?

As for lenses not having the apertures advertised, I think that perhaps English opticians are a little more conscientious in this

matter than Americans, although I can be by no means sure. Very often, where "aperture" is mentioned, or is inferred by stating that the angular aperture is so-and-so, and giving the equivalent focus of the lens, it is found that the diameter is actually that of the glasses of the lens, and that the cell cuts it down very appreciably, or that a fixed stop contracts the working aperture. In judging of the latter matter, however, it should always be borne in mind that, in the case of double combination lenses, the fixed aperture may be a little less in diameter than the front combination without cutting off any light, because this light is somewhat concentrated by the front lens before it reaches the stop.

There has been a great improvement amongst English opticians within the last few years in the matter of the accuracy of cutting stops. It is not so long ago that they were cut at pure random. Even for some time after certain opticians professed to have adopted the Universal Standard, the stops were seldom even approximately in accordance with it.

"Editors and Lenses."

Now for the editors and others who write in the periodical press about lenses. To the like of myself, living thousands of miles from the nearest place where photographic lenses are made, it is of the first importance that the descriptions of new lenses given in the photographic periodicals should be intelligible. Sometimes they are; but, alas, how often they are not! By the same mail that brought the issue of the *American Journal of Photography* above mentioned, there was brought a copy of an American contemporary—a journal that I value much, because it is edited by two people of talent, and the reading matter is generally excellent.

Under the head of "Editorial Comment," I came on a paragraph beginning, "An improved lens." This at once attracted my attention, the more particularly as, after a few preliminary remarks on the "wonderful discoveries made in optics and chemistry," it was stated that the lens is made of the new Jena glass. Now, I particularly want to know something definite about the results of the use of the new Jena glass for photographic lenses. The next statement, however, is, to say the least of it, confusing. It read that "it is made . . . . single, rapid, rectilinear, and wide-angle, and does, as the makers claim, work with full aperture, sharp to the edges of the plate." This remarkable statement wants a deal of consideration. Is there actually one lens that combines all the qualities here mentioned—that is, at the same time, "single, rapid, rectilinear, and wide-angle?" Although there is nothing in the "Comment" to clearly indicate it, I am forced to suppose that there are three different kinds of lenses, because, for one thing, I imagine it is impossible, even with the Jena glass, to make a lens having all the qualities indicated above. What on earth use it is to know that "it . . . . does . . . . work, with full aperture, sharp to the edges of the plate," without any statement of focal length, maximum aperture, or size of plate, is a thing that I leave to your readers.

A little lower we learn that "those of long focus are something like the new lens of Dallmeyer, which is making such a sensation abroad." One is inclined to interpolate, "Something like a whale."

But at this stage comes the most interesting part of the whole description. We learn that "the great value of the lens lies . . . . in an attachment which can be put in place of the rear combination, and produces actinically modified rays of light, thus reducing harsh contrasts, and obviating in portrait work the necessity of retouching. The results as described are remarkable, and give much the same effect as orthochromatic plates." Remarkable! I should think so, with a vengeance! A lens obviating the necessity of retouching, and giving the same effect as orthochromatic plates!

Leaving on one side the extraordinary property of a "rear combination" that can "produce" rays of light—whether in the vulgar sense of originating, or in the geometrical of extending in the same straight line—what in the world can this attachment be? At first it seemed to me that it might be a diffusion of focus arrangement, although it is difficult to see how that could give "the same effect as orthochromatic plates," and I hailed the information with pleasure, for a landscape lens with a diffusion-of-focus arrangement is still a *desideratum*. What comes farther on seems, however, to contradict this idea.

It presently transpires that "we have only tried the ordinary rapid rectilinear, but have ordered the violet light attachment." Angels and ministers of grace defend us! What does this mean? I thought that all the lenses, if there were really three of them, were not ordinary, but extraordinary, particularly considering that "those of long focus are something like the new lens of Dallmeyer." Then, if only "the ordinary rapid rectilinear" was tried, how about the implied evidence that it, this three-in-one lens, in all its forms was found to work with full aperture to the edges of the plate "as its makers claim?" But the "violet light attachment" beats all.

For the nearest approach to definite information that we have in the "Comment" is that "Miss Barnes will probably use the lens in her European tour the coming summer."

Surely we may demand with reason that the manufacturers of lenses shall describe their goods a little more intelligently than they do, and that commenting editors, unless they can tell us something more definite about lenses that they have tested than do these referred to, should hold their peace.

Over the editors we have no control. Over the opticians we have to a certain extent, and I suggest that all photographers should do what they can, by promptly returning lenses that are not in accordance with catalogue description, demanding either a return of their money or a lens that is in accordance with the description. Farther, that, where other things are equal, they give their custom to those opticians who issue intelligible catalogues, and whose goods are found to be in accordance with their advertisements.

W. K. Burton.

ADVANCED PHOTOGRAPHIC WORK FOR AMATEURS.

VI.

In a former article I referred to platinotype printing on cloth, materials for which are readily procurable from the Platinotype Company, and no sooner will an enthusiastic worker have entered fully into and enjoyed the satisfaction of what may justly be termed an uncommon phase of photography than most probably he will fly at higher game and long to produce his own printing material. In so far, however, as the production of sensitised nainsook, or other similar material, in platinotype is concerned, I fear there is but little prospect for any one not thoroughly conversant with the intricacies of the process ever being able to successfully prepare this in an amateur manner.

There are, however, other methods of printing on textile fabrics which an enthusiast may with ease undertake in the knowledge that perfect results can be obtained. These are sensitising the fabric by silver, or practising what is termed the blue process. Most exquisite results can be obtained with the latter, and the entire operation may be conducted without any great outlay or acquisition of any special apparatus. As I have said previously, the first necessity is a suitable negative, without such no success can possibly attend any attempts at printing on cloth. Having, therefore, a bold, vigorous negative which possesses clear glass in the shadows and strong density for the high lights, an amateur may, however, set about the work with the utmost confidence. In selecting a suitable fabric, there are quite a number of materials at hand in any lady or gentleman's wardrobe with which a start may be made, to wit, a good linen pocket-handkerchief; let it, however, be a good thick one. This is first washed, and all soap and other matters carefully rinsed out; it is then well ironed without being folded. The next operation is the preparing of the surface of the handkerchief with a partially insoluble solution of gelatine, whereby the sensitising solution, which is afterwards to be applied, is so held *in situ* as to yield a good print when exposed in the ordinary manner in a printing frame. This gelatine solution is prepared by dissolving fifty grains of gelatine in twenty ounces of hot water; when dissolved take into the dark room and add to it thirty grains of bichromate of ammonium dissolved in an ounce of water, stirring vigorously. Keep this in a stone bottle.

Let it now be supposed that it is desired to print a portrait on the corner, centre, or any other portion of the handkerchief. Whatever part be chosen is carefully marked off with the aid of a soft lead pencil (let us suppose it to be the centre). The handkerchief, previous to the application of the gelatine solution, is carefully laid down on a clean sheet of glass or other suitable support, and then, by means of an oval, round dome, or any other suitable shape, the exact spot is marked with the pencil (a very convenient round shape may be had by using a saucer or wine-glass). The handkerchief, after being pencil-marked, is stretched drum-tight over a common school slate (if you are not a good hand with the needle yourself, get a lady friend to do it for you); now, with a tuft of cotton-wool or clean flannel, in the dark room, swab well the part marked with the pencil with the gelatine solution, and set aside to dry in the dark. Now get a large sheet of black needle-paper, or, what is better still, stiff, blue sample paper (the latter cuts better, not being so fibrous), place the same flat on a sheet of glass, and with a narrow-pointed penknife, using the same round shape, cut out in the centre (or wherever it is required) a nice, clean-edged mask; try and get the edges free from jags (the blue sample paper, being nice and hard and crisp, will permit of this being done, provided a very sharp knife is used). This cut-out centre, with its large margin (the entire sheet of paper), is

pasted carefully on a 15×12 sheet of glass, or sometimes smaller sizes may be employed, but a large frame is more convenient.

When the handkerchief which has been swabbed with the gelatine solution is perfectly dry it is folded so as to be capable of being placed in a 15×12 printing frame; the circular pencil mark will now correspond with the cut-out portion of the mask, which is a fixture on the glass of the printing frame, and in a room lighted by ordinary gaslight the prepared portion of the handkerchief is so adjusted that the pencil lines correspond with the edges of the mask. The back of the printing frame is then placed over the handkerchief, the springs tightened, and the handkerchief exposed to sunlight for several minutes, say about five. The next step is the preparation of the blue sensitising solution.

Get two stone gingerbeer or stout bottles, and in 8 ounces of water dissolve 830 grains citrate of iron and ammonia. (Label, No. I.)

In 8 ounces water dissolve 600 grains ferridcyanide of potassium. (Label, No. 2.)

These solutions are not to be mixed until immediately before sensitising. The handkerchief and the solution must be kept from the light.

The operation of coating the linen fabric had better be delayed till nightfall. The handkerchief is then stretched out flat by any convenient method, and the portion marked with the pencil is then well swabbed over, using a piece of flannel, with the sensitising solution mixed in equal parts of No. 1 and No. 2.

The handkerchief is then set aside to dry in a dark room. This is conveniently done in a warm kitchen just before going to bed, but care must be exercised that it is removed before daylight.

The handkerchief is now ready to be printed. Let us suppose it is a suitable half-plate negative that is about to be used. I have always found in practice that when such large articles as handkerchiefs, or in cases where the sensitised portion of the fabric has not been cut off in suitable sizes to fit small-sized negatives, that it is advisable to use as large a frame as possible for the purpose of printing, therefore a 15×12 size at least ought to be employed. I have known a pupil of mine bring into requisition an oak picture frame having a good thick glass set in it, but a good printing frame is the correct thing to employ. The 15×12 sheet of glass upon which has been pasted a cut-out black mask, of the same shape, but slightly smaller than the negative, is inserted, and then the negative is carefully laid over the cut-out portion, and fixed in position by binding the edges to the glass with strips of gummed paper. Pieces of cardboard of the same thickness as the glass of the negative are then placed on the large sheet of glass so as to pack the negative as it were. This is done to prevent any liability of the glass to break when the springs of the printing frame are tightened up.

As a rule, this class of printing is best done with the aid of suitable masks laid over the face of the negative, but such can be vignetted if desired. When amateurs are merely printing small-sized negatives, say not over whole-plate in size, any photographic dealer will supply cut-out masks from lantern up to 8½ × 6½ sizes, and these in all shapes, including ovals, domes, squares, &c., &c. When the negative has been fixed on the printing glass a suitable cut-out mask is placed over the face of it, and fixed by means of slight application of gum to the corners. All is then ready for the printing operation, and the handkerchief is then placed so that the sensitised part occupies its correct place on the negative. As a rule, very full printing is desirable, and now will be seen the need of using only such negatives as are bold and strong in contrast. When fully printed, the handkerchief is taken and washed in clear *cold* water; this will remove the unaffected gelatine, and develop out the picture. Don't be afraid to wash well if you have properly prepared the gelatine solution and exposed same to sunlight, the image will stand good washing, and be all the brighter and cleaner for it.

In reality, there is no difficulty in this class of work, and I have known ladies and gentlemen who have derived more genuine pleasure from producing one good print on linen than fifty on paper.

T. N. Armstrong.

MARINE PHOTOGRAPHY.

Too little attention is, we think, says *Anthony's Bulletin*, given to marine photography. True, we have seen many dismal failures—black hulls sailing on a mingled sky and ocean of such dazzling brightness that sails, masts, and ropes were but theoretical and paltry accessories, faintly suggested by certain dim and ghost-like outlines. On the other hand, views of such entrancing beauty and clearness have been submitted to us, showing the results of proper care in composition and lighting as to make it a matter of wonder how such dismal failures as those first referred to could have been produced when all necessary materials for such perfect pictures were at hand. It is with the view of giving some fundamental principles necessary to success in this direction that this article has been written.

A hand camera is, of course, well-nigh indispensable for this sort of work, both for the sake of portability and by reason of the fact that instantaneous exposures are here the almost invariable rule. As to lens, nothing, to our mind, can exceed an ordinary single-view lens, focussed for a distance of, say, fifty feet. In this way an extended sea view, even while including a generous foreground, will not be lost in mistiness on the horizon, and an effect similar to the indistinctness of a portrait background will be avoided.

For yacht views pure and simple, a wide-angle lens is preferred by many, depth of focus being in this case secondary to crispness of definition in the centre of the field. A rather large stop, with excessive speed of shutter, will be found to give, perhaps, the best results, as, in a brisk breeze running free, the velocity attained by one of the crack yachts is by no means something to be despised or overlooked. Couple this with the fact that, in many cases, the standpoint of the operator—often a naphtha launch—is violently pitching, as well as moving ahead at the rate of ten miles an hour, and it will readily be seen that quickness of exposure is everything.

By all means use a shutter with a pneumatic release. It is almost always necessary to make the exposure on the instant, or the chance is lost. A quick, sudden pressure on the button is almost certain to seriously jar the camera, while a vigorous and impulsive squeeze on the bulb is free from any disastrous effect. Brace yourself securely against the gunwale of the boat (if it is high enough), and you will often avoid an ignominious tumble, broken camera, and a magnificent expanse of cloudless sky on the plate, where you vainly hoped to see bulging canvas, straining ropes, and prow half buried in foam from that big billow which was the cause of your own downfall.

The objection may be made, that an enthusiast is needed for this kind of work, together with a camera endowed with qualities nearly approaching those of mackintosh. Even granting this, we say that such a combination is easily to be found, and, when working in unison, it will produce a collection of views in which gracefulness and vigour of action are combined in a manner impossible with any other class of subject.

The lens should, if possible, be shielded completely by the shutter; this will prevent the spray from injuring, for the time being, its picture-making qualities. Avoid bright metal-work on your camera, lens, or shutter. Have all blackened, and as little of it as possible, to avoid the corrosive action of the sea water. A hard-rubber shutter is best, as it is less liable to stick when wet than any other kind. Of course, we have chiefly depicted a rough-weather experience, knowing that the trouble and wetting will be amply compensated for by the results, these, to our mind, being far in advance of any mirror effects, so far as yachts are concerned. Not that we wish to be understood as decrying the merits of the beautiful reflection work so often seen; but something full of vigour and snap, showing Neptune in his wilder moods, is preferable to a tranquillity, which, while beautiful and suggestive of the fabled lands of the lotos-eaters, is more suitable to a landscape than a sea view. A roll of film is preferable to anything else in this case. Often you will pass a yacht and then another in quick succession, too quick to change your plate-holders, which perhaps are wet, and the slides stick. Or you want two views—one approaching, and the other receding. With plate-holders you can, of course, get the first, but by the time you are ready for the second it is just tantalisingly out of reach. Besides, the illumination is almost always intense, and many a fogged plate will result from a hurried and careless withdrawal or replacement of the slide.

The lighting in a marine view is all-important. Remember that the sky in your picture will be a dazzling white background, unless filled with clouds, and a white sunlit sail will not show up against it with anything like the distinctness apparent in looking at it in nature. Again, the water is a powerful reflector, and, though apparently dark in colour, will, under a noontide glare, come up in a developed negative almost, if not quite, as dense as the sky above it. Have your camera so pointed that the sun is to your right or left at an angle of about 45°. By so doing, ropes, sails, and hull will be thrown in partial shadow, and ensure a contrast in your finished print which would otherwise be woefully lacking in this respect. Make your exposures in the morning or afternoon rather than at noontime.

Never take a beam view of a vessel with her sails trimmed flat as boards; there will be neither life nor action in it, and the mass of white, if brightly illuminated, will be scarcely distinguishable against the high lights of the sky and water background. Even with a cloudy sky, and but little direct sunlight, there will be enough reflection for a quick exposure, and a full light on sails and hull will then

give both contrast and detail. Under any other conditions, it is better to have the sails in shadow, or, at most, but partly lighted.

Almost any good developer will serve for marine exposures, but it should not be used full strength, as with snap-shots on land; otherwise plenty of detail, but insufficient density, will result. Develop slowly, and with rather dilute solution to start with. Hydroquinone is especially adapted for use here, as the image comes up slowly, and with plenty of density.

Beware of over rather than under-exposure, as it is hardly possible to fully realise the immense amount of added light, due to reflection, in a seascape. It is usually possible to make a satisfactory instantaneous exposure, even on an overcast day, on the water, and many prefer for development the iron and oxalate solutions so largely used on the continent of Europe.

Pretty moonlight effects can be obtained by having the light shining directly in the camera, making a short exposure, and developing for density. In this case a film is again preferable to a plate, owing to the freedom from halation in the negative produced.

We have made no mention of surf or combined shore and sea photography up to the present, but, properly handled, these subjects are capable of producing grand results. Bold masses of rock in the foreground, over which huge swells are breaking, can be made most effective use of. Have the rocks, if possible, in shadow, and the sun at a right angle or rather more to the direction in which the camera points. The crest of the waves will then reflect the light, while the reflection from the main body of the water will be avoided, and the true effect of the dark billow breaking into white foam along its crest will be obtained.

The extreme dampness and corrosive properties of the atmosphere at the seashore must be taken into careful consideration. The metal parts of the camera will rust and stick if not carefully watched. If plates are used, unusual care must be taken not to touch the sensitive surface, as finger marks will surely result. This applies to films as well.

Have hard-rubber slides to your plate-holders, if you would avoid sticking and jamming, and the consequent loss of many a picture. Your woodwork is liable to stick, and tight fits become impossible ones when exposed to long-continued dampness.

But, with all this appalling list of drawbacks, the enjoyment of one good yacht race, and the collection of negatives that care to the details of lighting and exposure will give you, will far more than make up for the incidental wettings and mishaps that may fall to your share.

PHOTOGRAVURE.

Photographic Society of Great Britain.]

This subject presents itself to the mind in a changing aspect as time goes on. Indeed, most things do. The early stage has a different air from that of progress or maturity. A romance and a feeling of expectancy gradually changes into a critical and judicial attitude.

That which most induces this thought is the immense thing that photography itself has become. In nothing has the expectant aim and that anticipatory joy of the mind in the future achievements of our sciences been so marked as in photography and its artistic aims. It is too great a diversion to even name the leading branches of the art-science and their relation to our aims and desires. But it is worth while to give a definition of the aim of all photographic art as "that which can autographically place on record all that can be seen with the eye, or that might be seen if we had powers as great as our methods or chemicals," as these go so far beyond the optical power of the visual organs. When a photograph not larger than a halfpenny shows 50,000 stars, one, of course, is bound to wonder greatly at the result: fifty years ago it would never have been dreamed of. The bare idea that we should ever be blessed with such an all-potent thing would simply beggar the mind of any one living one hundred years ago.

This it is which puts each of the branches of photographic art into line. Photogravure is only one of the very many and growing methods of making a photographic picture. And the operator of one method—such as collotype, for instance—is as far removed from the one who takes a portrait as possible. The many details that belong to each and every branch quite separate them, and so separating cause the whole to spread out in one enormous field of work that few of us ever consider as a whole. It seems to me impossible for one man to grasp all the multitudinous details of every branch of the photographic art. Those details constantly expand; from year to year new details are introduced and discovered, and it is quite impossible for one mind to master all of them.

Of general remarks I will only name one more; it is that concerning progress. One can never try, or learn, or practise too many details and methods in the particular branch that you study. The steady working of a formula is very well, but the vast accumulation of trials and failures recorded in the mind, or in some more tangible form, go steadily to make progress, because one or another *long-disused method*, combined with *new materials* and in a *new way*, produces a new discovery of great value. The very wrecks of the past are sorted over, and morsels picked out to find out an important place in some grand new method. I apologise for this long introduction, but a great respect for the workers of the past, and also of the present, compels this form of acknowledgment. To how many workers living and dead is the photogravure operator a debtor; and how many apparently insufficient things are brought forward to produce better results now. This is the leading idea which I would emphasise, for it is the golden thread of future victories in this and every branch. We appreciate, of course, the charm of an old ruin—there is nothing like it. An old ruined abbey adds a quite peculiar grace to an English landscape; but it could never have existed had there not been a most expensive building to ruin, and the charm would never have been there had there not been an enormous expenditure of time and labour in producing the delicate tracery. You must view the work of those men before us very much in that light. Dr. Hunt, of Redruth, Cornwall, was such a worker. His knowledge and patient care in studying the physical phenomena of light met with but little reward, you might say, in his time; but he lived long enough to see a great many results, and he was one of the noblest workers of his time. Our results at the present time largely follow from the work of men who have been a good deal less fortunate in seeing those results than Dr. Hunt was.

The "Main Aspects" of Photogravure.

Photogravure presents itself to my own mind in three main aspects:—

1. Its economic aspect as regards "cost," "outfit," "speed," and their bearing on the different classes of published matter.
2. Practical aspect, methods of production and relation to the class of work in hand, together with all technical details.
3. Suggestions for the future, and particularly as to new openings.

The economic or the practical aspect would, either of them, furnish enough points for a long essay; but I will run quickly through the principal ones in each case. In the paper which I had the honour to read before the Society of Arts some years ago the economic aspect was only touched upon. This time we will look into it more fully.

The first and most important item on the economic side is that of printing cost. The limitations of printing cost are almost as well fixed as those of getting coals, or any such service that you can think of. For printing we employ a class that we find ready to our hands: the copper-plate printer of many years' standing is our printer, and thus we are in front of a standard cost in production which cannot vary very much; and the chief point that one ever notices is the greater or less ease with which one or another plate can be printed, thus getting more prints in a day from an easy-printing plate than a difficult one. One plate must cost sometimes twice as much to print as another, and yet to the public and the customer is apparently no different, and they say, "Oh, why should you charge twice as much for this as for the other?" But, if you do not, you will lose; you cannot help it. Mezzotint engraving is very slow to print, and photogravure, if it is of that full nature, is also slower to print; but a slight, sketchy effect, however catching, is quicker to print. The mezzotint is the slowest of all methods to print. The little impressions in the old mezzotint are something like V. Big and little, big and little, all of a certain shape. Now, a V-shaped impression does not hold so much ink as U, the cavity is not so capacious; if the points go off a very little bit, the cavity has still less capacity. Yet there is one charm of the old mezzotint which we never can get; when it is scraped away to produce a light tint, you retain those little punctures. Now, processing, in so far as I have seen, is unable to produce that detached puncture for the light tint. That little puncture, producing comparatively widely separated dots, gives a large area of perfectly clean paper; thus the lights of a mezzotint are more beautiful than the lights of our process plate. The process plate has a tendency to be like ~~~~~~~~~~~~~~~~ in the light—it does not matter by what method the plate is made—and the consequence is there is not much clean paper between them. The colour is easily got out by the press, but it is not clean work. Then, if you scrape it out with the scraper, it is a very clean white; but with the former it goes in a sweet way, leaving a little bit almost to the last. The necessity with regard to the mezzotint plate is that V, not holding so much ink as U, requires very stiff ink. The man has to grind that ink till it is as stiff as putty; and, when ink is as stiff as putty, it takes a good deal of patience to clean it off, leaving a nice layer all through the plate so that it may print full and nicely, because, if it is not stiff, it comes

out of the cavities and will not print a dark tint. Now, we have good deep cavities, and with a comparatively thin ink we can leave enough to print a dark tint. Consequently, the photogravure print is economical to make. You have to remember that the old plate is more expensive to print than any chemical plate that we can make, so that on that ground you can talk to the old printers and say, "Yes, they are expensive; but they are not so dear as mezzotint plates." Having now shown the mezzotint plate to be a hard plate to print, we go off to another point. The cost of printing and paper seldom gets much below one penny per impression for ordinary sizes. (We pay 8*s.* for the portfolio size, which is about *Art Journal* size, ten inches long. That costs a penny per impression for labour only in printing. You have to remember that engravings would cost five or six times as much; they must print 7000 to 10,000 to make it down to a penny per impression, to pay for the plate—in fact, I could have shown you a plate which cost 100*l.* to make. I suppose there would be 3000 or 4000 printed from it; but, of course, that does not pay 100*l.*, except at several pence. When you go piling on the pence, then comes the difficulty with the public; they do not see it.) And when for a penny paid out you have, according to the modern economic situation of the bookseller, to charge the public twopence, it is easily seen what a charge this becomes. This is the greatest drawback, economically, to photogravure. Many a job is done by the collotype method because it has a low cost for the first print made, while photogravure is high; but, for a record, collotype depends on its negative, which is more frail than the costly copperplate, and therefore unsuited to a standard edition of a book. Of course, you could with collotype go back to one impression and say, "That is a record." But I dare say you all know how "process on process" degrades the result. You take a photograph from a photograph—it is so much—behind it. It is better if you can go back to a standard that you can depend upon.

Methods of Economising.

For a book of small or moderate size the old method of grouping four subjects on one plate is good; for one pull of the press, and just a little more time at inking, produces a lot more prints, and the printing cost can be brought down to, say, half of the former figures. The cost of making the plate with four pictures on it is, however, no less per subject—probably more.

Another method is by printing several subjects quite close together on thin China or Japan paper, and then cutting up the sheet by hand and inserting where required. This, though not economical to the extent one would wish, opens up methods of accommodation of great value. Thus prints may be made long before the book is ready, and they can be used for any purpose or book by simply pasting them down. You can put the prints by for years, and when the list is complete you can print the book. The book is printed with the blanks, and that work is cheap; but, if you try to print in these blanks from the press, you would find it extremely expensive. We have tried it for a Scotch publisher; but it was no use, it could not be done. The best way is to print on very thin paper—China paper preferably—and then paste them in. You cannot put a thin paper through the press and expect it to print. You have to put a piece of thick paper at the back, and then it will take the ink.

The printer has to use a backing of thick paper to get a proper impression on the thin, so that economy is not apparent unless five or six are on a plate; and, if they are neatly brought together, they can be cut up for a trifle. Then comes inserting or mounting, for which no great skill is required, so that you can get very cheap labour—girls, for instance—for it. Drying the sheets flat is yet another expense, and it seems either to want redamping to do this, or to have them already damp when the pictures are inserted. This all costs something, yet with a willing staff and a good shop it is inexpensive and certain.

The large work by W. J. Linton, a copy of which is here, is got up in this manner, the subjects being grouped on the plates and then printed on thin China paper, and so cut up and mounted. The same method may be used for the many little elegancies which are now so much in vogue—memorandum cards, birthday cards, &c., subjects being stocked in a cut state ready for mounting on cards or leaflets, of any size, or shape, or kind. Collotype, of course, gives some idea of copper-plate work: but, unless it can be printed on the thin paper and without any gloss, it cannot have the rich, velvety character of an intaglio print.

The great point is that, however thin the paper, you can get the rich effect of the print upon it; there is no inferiority. (The pictures in the *Life of Samuel Palmer* were quoted as an instance.)

I have dwelt rather long on this branch, because of its true importance, it being charged in every phase with questions of economy and the balancing element of quality, how much quality to how much money? That is the question for to-day in every business.

Speaking before photographers, I may record my surprise that photogravure portraits are not more commonly made use of as presentations where a large firm employing numbers of persons desire to remember an honoured employer by executing a plate of his portrait, and using the copies as the presentation. Many similar purposes suggest themselves, the favourite secretary or chairman of some association, not to speak of ladies of similar eminence, head masters and principals of schools and colleges, officers, captains of ships, &c. At present we have heard of Members of Parliament doing something of this kind, but it might go further with great advantage.

Art Aspects.

The failure of so much of the old copper and steel-plate engraving follows rather from the business demand than from the artistic, or, at least, it is equally divided. Cheapness was called for, and photogravure plates of a fair quality can be made cheaply, but they cannot be printed cheaper because the process is identical. Line engravings in steel are printed very cheaply, because a clean surface is all that is desired and steel easily yields it, but steel engravings are slow and hard to produce. Copper etchings are not so hard to produce, but even when steel-faced they generally give trouble through being finished with very fine work. Mezzotint costs a deal to print, but here is the closest rival of photogravure, and it costs, say, twice as much to print as the photographic rival. The artist's own particular feeling is far different, and merits chief attention, because, sooner or later, it is what the artist feels that the public will also feel, and it is right that the creative mind should lead the receptive mind. This being granted, it follows that the artist's idea of a perfect rendering in printing ink should be consulted. When we cannot consult it, it will be needful, on our own responsibility, to render it not with a mean and niggard neatness, nor with a rough, blundering ruggedness. If I might define the ideal photogravure, I would say that the touch should be clearly perceived, but so also should the transparency or opacity of the original be rendered. This is a hard thing, but let it be remembered that the old mezzotint engraver would, in his best work, give two or more distinct tints, one fine, another coarse on top of it, and the result was increased transparency.

When they rock a plate there is one tint all of one size—that is, when they first prepare a plate. When they scrape that, it is converted into a gradation of one degree. They find it does not hold ink enough. They now take a bigger rocker and go over all that work, and the peculiarity of it is—the rocker that they pass over it having a larger arc—that it goes lightly on the hollows, and the hollows are the lights. In the mezzotint method *these* (hollows) are the lights, having the little digs in them; *these* (hills) are the darks, having the deep digs in them. So that, when the rocker goes over it, it opens the hollows a good deal, so that re-rocking does not destroy detail to the extent that one would think; and a very light scraping over all these parts is easily done, and the result is that you have two tints, a bigger tint and a smaller tint. Now, if you go over the road to that institution (British Museum), you can see in the Print Room all sorts of mezzotint engravings, and you will find that the best are those which are twice rocked; some are even three times rocked, and three times scraped out, and sometimes they rock and scrape out portions only. The consequence is that the old plates were extremely rich—I cannot see my way to do that in processing.

Thus I do not like a hard equal tint in photogravure if it is to render the best result. Rather let one granulation cover another, and one procedure be seen through another. I am very particular about this, because now we approach a very big subject—half-tone in relief. Let one texture be seen through another texture. It is a better thing than graduating the texture according to the colour. That is very good, I will allow; but every part of the plate should have more than one texture upon it, and then you get transparency. Then, I find the great difficulty in meeting art requirements lies in the narrowness of the photographic scale as compared with that of the painter. Our modern dry plates certainly, when well handled, give a nice range of tone, but the negative is not the end of the work, and in all the *physical work* which follows I have found the scale much cramped at both ends. I have to make my lights and also my darks to a large extent artificially. We cannot help it. Bichromate, to satisfy an artist, ought to bite into the blacks deeper and deeper as it goes, but it does not—it stops. Where the gradation of light is in a steady ratio, the gradation of printing starts with a fair effort, and then it gradually gets more flat; and where we want the tones to grow and grow they do not grow, the reason being generally that it is full of pigment. It is only when there is no pigment in it that you get a really good scale. I steadily refuse to see in work turned straight off at one operation any good result if from a full-toned subject.

A. Dawson.

(To be concluded.)

RAYMENT'S IMPROVED CAMERA.

In the early part of the year this instrument came under our notice for review, when we had to record several very important improvements which had then been applied to it. Now a still more elaborately perfect instrument is presented to our attention. Throughout the camera and dark slides are bound with aluminium.

A roller-blind shutter is now enclosed within the very thin front or lens board of the camera. The lens projects inwards towards the focussing screen—both the shutter and lens are entirely hidden from view, and neither requires to be altered when the camera is set up for exposures, as the same space and position is occupied by them whether the instrument be opened or closed—thereby saving considerable time over the old mode where the tedious necessity exists for the lens to be first screwed to the front of the camera, and then the shutter to be connected with the lens. The "Optimus" lens flange is now employed, so that, should a number of lenses be carried, one can be instantaneously substituted for another. A further handy arrangement now exists which, when short-focus lenses are used, enables the operator to rack the telescopic portion of the base-board backwards towards the focussing screen. The screen being made to slide towards the front or lens board makes it convenient for lenses of the shortest-known focus to be used.

Coupling these conveniences with those already enumerated in our earlier notice, we have no hesitation in ranking this as one of the most comprehensive and perfect cameras which have yet come under our observation, while the superiority of workmanship and general taste displayed in the get-up of the whole apparatus are probably unsurpassed.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
August 15	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 15	Hastings and St. Leonards	
,, 15	Leeds (Technical)	Mechanics' Institute, Leeds.
,, 15	South London	Hanover Hall, Hanover-park, S.E.
,, 16	Oxford Photo. Society	Society's Rooms, 136, High-street.
,, 16	Southport	Shaftesbury-buildings, Eastbank-st.
,, 17	Bury	Temperance Hall, Bury.
,, 17	Manchester Camera Club	Victoria Hotel, Manchester.
,, 17	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 17	Portsmouth	Y.M.C.A.-buildings, Landport.
,, 17	Southsea	
,, 17	West Surrey	St. Mark's Schools, Battersea-rise.
,, 18	Brixton and Clapham	Gresham Hall, Brixton.
,, 18	London and Provincial	Champion Hotel, 15, Aldersgate-st.
,, 18	Oldham	The Lyceum, Union-st., Oldham.
,, 19	Cardiff	
,, 19	Holborn	
,, 19	Leamington	Trinity Church Room, Morton-st.
,, 19	Maidstone	"The Palace," Maidstone.
,, 19	Richmond	Greyhound Hotel, Richmond.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

August 4.—Mr. G. W. Atkins in the chair.

The following gentlemen were elected members of the Association. Messrs. A. Black, E. A. Leblanc, J. F. Shew, J. Guardia, and W. D. Welford.

It was decided to accept the invitation of the Photographic Society of Great Britain to contribute a collection of lantern slides for display during the evening exhibition.

Mr. R. P. Drage read the report of the Association's delegates (himself and Mr. J. Weir Browne) to the Edinburgh Meeting of the Photographic Convention of the United Kingdom [see p. 518]. A vote of thanks was passed to the delegates for their report.

Portraiture Without a Studio.

Mr. W. E. Debenham gave a brief discourse on this subject, remarking that, though studio portraiture gave the most agreeable effects, on account of the lights and shadows falling in different directions, which brought out the features in relief, photography without a studio could be made to approximate to studio conditions. If the person to be photographed were placed on an open heath, they would have the light in all directions, but get a flat representation, the effect on the whole being weak, the top light predominating. With a house on the heath, and the sitter in front of it, the house would keep a great deal of light from the face, but the top light would be excessive. Matters would be reversed, however, by placing the sitter near the house, the light being cut off by the house behind, while a wall at the side would fulfil studio requirements, and they could thus get portraits scarcely distinguishable from studio work. He had taken successful portraits in this manner in collodion days which would have been almost impracticable to get indoors, and showed several examples. As regards portraits indoors, lighting by reflection made one independent of windows. Rembrandt effects could be obtained by placing the sitter near a window, and lighting the shadow side by reflection, using a large surface. The reflector, however, should not be placed at a great angle.

Mr. A. C[illegible]an had taken portraits out of doors of the Khedive of Egypt, in the manner suggested by Mr. Debenham, and it had been impossible to tell whether they were studio pictures or not.

Mr. Debenham remarked that portraiture out of doors was practised before studio portraiture.

Mr. Beckett said out-of-door portraiture was easier for amateurs than studio work.

Mr. Debenham said the side reflections should not be carried too far back. In regard to the use of magnesium and daylight, he thought the flash would cause a second high light in the eye. He did not think a silvered mirror as good as a sheet, as the latter had a larger surface.

Mr. J. S. Teape had used a small flash on the dark side, and found it a great improvement. He had not found the two lights in the eyes. The daylight overpowered the small flash.

After a vote of thanks to Mr. Debenham, the meeting adjourned.

North Middlesex Photographic Society.—August 8, the President, Mr. J. W. Marchant, in the chair.—Thirty members were present, and four new members were elected. The Secretary was called upon to open a discussion upon the various methods of obtaining harmonious prints from harsh negatives. During the evening Messrs. Pither, Cherry, Cox, Forbes, Gill, and the Chairman spoke on the subject. The method of harmonising harsh negatives by rehalogenisation and redevelopment was chiefly dealt with, and prints from negatives before and after treatment by this method were shown, and a demonstration of the process was given. Prints from negatives taken at the outings to West Drayton and Boxmoor were entered for competition. The vote of merit was accorded to Mr. Wall for West Drayton, and to Mr. Cherry for Boxmoor. A vote of thanks to the chairman concluded the business. The next meeting will be held on August 22nd, when Mr. Wall will take the chair, and Mr. Debenham will address the Society upon "Carbon Transparencies." Visitors welcome.

Hackney Photographic Society.—August 2, Mr. W. P. Dando in the chair.—Members' work was shown by Messrs. Capel, Nunn, & Reynolds. Mr. Dando showed a series of views taken whilst with the Convention. Question asked: Why does the P. O. P. print sometimes purple and sometimes red; and which gives the best toning? Reply; when fresh, it gives the purple tint. With absorption of moisture the paper prints the red tone, which is preferable, as it tones to a richer shade. On Bank Holiday the Society had a whole-day excursion to Dorking and Gomshall.

Harlesden and Willesden Photographic Society.—August 7.—Mr. Clapton gave a lecture upon the subject of lenses. The Secretary, Mr. Woodbury, of 23 Fairlight-avenue, Harlesden, is particularly desirous that the existence of this Society be made known to the numerous amateur photographers residing in this and neighbouring districts, and will be happy to give all information to those likely to join.

South London Photographic Society.—August 4, the President, Mr. F. W. Edwards, in the chair.—The evening was devoted to the explanation and demonstration of various "printing processes." Mr. G. H. Moss described at length the method of preparing and coating of paper by the collodio-chloride printing-out process, and showed specimens of work on paper of his own preparation. The Fry Manufacturing Company exhibited some pictures printed on their Soltype paper. The manipulation of this paper appeared to be very simple, and the tones of the finished prints were much admired by the members present. The Honorary Secretary suggested, as an aid to focussing, the fixing of microscopic cover glasses to the focussing screen with Canada balsam, which enabled a focussing eyepiece to be used with great facility. It was announced that the President offered a prize for the best picture produced on the sample Paget plates, a large number of which were distributed at the meeting; the result to be judged on the 5th September, 1892.

Bath Photographic Society.—July 29, excursion to Castle Combe and district.—The party, including several ladies, left the city by brake, and, proceeding through Box, Corsham, and Pickwick, reached Castle Combe about two o'clock. Here they were received by Dr. Sudlow, who drove with them to Grittleton House, some two miles distant, the seat of Sir Algernon Neeld, Bart. The house is of very beautiful proportions and design, with richly ornamental grounds. Having viewed these outside attractions and photographed them, the doctor, armed with the necessary permission, conducted the Society through the two spacious picture galleries, filled with very valuable paintings and statuary. Returning again to Castle Combe, and after a brief rest, the doctor piloted the Society through Mr. Lowndes's beautiful park, where more photographs of the Manor House and adjacent attractions were obtained. At seven o'clock the party returned to the Dower House, Dr. Sudlow's residence, where tea was awaiting them, and two hours later the departure from this delightful valley was taken. During the return journey a hearty vote of thanks was passed to Dr. and Mrs. Sudlow for the arrangements and their hospitality.

Rotherham Photographic Society.—August 2, Dr. Baldwin (President) in the chair.—Petition against proposed restrictions on photographers at the World's Chicago Columbian Exposition, was agreed to. Hon. Secs. exhibited a series of ordinary silver prints, made twenty-eight years ago by a local worker. Although mounted, and no special pains had been taken with regard to them, they had undergone very little, if any, change. Prints on Eastman's gelatino-chloride paper were also shown, and were very favourably criticised. It was agreed that the third excursion of the season should take place on Saturday, August 13. The place chosen was the Ilsevlin Valley, near Sheffield. Mr. A. T. Cocking, mining surveyor, and one of the staff of the Frith College, Sheffield, then gave an address on photographic chemistry, confining his attention principally to change which salts of silver undergo in printing, and after-processes. His remarks were illustrated by several experiments. On Friday, the 5th inst., the council of the society made arrangements for the annual members' competition. There will be five classes, viz., A, six untouched negatives; B, three untouched negatives and prints therefrom (1892 excursion

work); C, four negatives and prints, open only to those who have not hitherto gained an award; D, six prints; and E, six lantern slides. At an Art and Industrial Exhibition, held in connexion with the Rotherham School of Science and Art, on July 28, 29, 30, and August 1, several of the Society's members sent specimens of work done. Certificates of merit were awarded to Mr. Rackstraw and Mr. Hemmingway.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 13,926.—"Improvements in Photographic Cameras, and in Films for use therein." J. F. PARSONS.—*Dated August* 2, 1892.

No. 13,977.—"Improvements in or relating to Photographic Processes." N. B. KENEALY.—*Dated August* 2, 1892.

PATENT COMPLETED.

IMPROVEMENTS IN PHOTOGRAPHIC DARK SLIDES.

No. 3598. WILLIAM MIDDLEMISS, Alice-street, Bradford.—*July* 9, 1892.

MY invention relates more especially to solid slides, and is intended to take the place of the small buttons or other fasteners usually used to keep the sensitive plates in position. At one end of the slide, on one or both sides, I fix a plate of brass or other metal. This plate is pivoted at one end, and the other end is made to move about a quarter of an inch. When it is required to fill the slide with the sensitive plates, this brass plate is moved back, and the plates dropped in; then the brass plate (having a spring behind it) moves forward, and projects slightly over the sensitive plate, and keeps it in its place.

One end of this plate is made to project through the side of the slide, so that it may easily be moved from the outside.

Correspondence.

ORTHOCHROMATIC PHOTOGRAPHY.

To the EDITOR.

SIR,—Returning from travelling, I find Mr. Edwards's letter in your issue of July 15. If Mr. Edwards is still of opinion that he *successfully* opposed my patent, I must leave him to the enjoyment of that view, in face of the *facts* put before him and your readers by Messrs. Allison.

I can duly appreciate counsels' opinion, but, as pointed out before, it rests on "*the evidence adduced*," and, that evidence being biassed beforehand, such "opinion" must necessarily be one-sided.

Let us, on the other hand, bring it against the uncontestable facts of scientific evidence, such as we have in this case—evidence attested by the highest authorities in such matters, and based upon *facts known*, and about which there can be little doubt of its correctness.

Such evidence, both English and Continental, we have, showing that, for instance, eosids of silver *does not form* when eosine is introduced with "ammonia as a vehicle" into the emulsion. Hence we have a right to conclude, with Dr. Acworth and others, that it is Mr. Edwards who uses Dr. Vogel's process, and not Dr. Vogel who infringes on the Tailfer patent.

I have sufficiently dealt with the question of keeping qualities, and if plates by my process do not keep, why should Mr. Edwards go out of his way to use it, as he evidently does. Have his plates never gone wrong? We know for a fact that they have.—I am, yours, &c.,

Berlin, August 3, 1892. DR. H. W. VOGEL.

THE NEW EASTMAN GELATINO-CHLORIDE PAPER.

To the EDITOR.

SIR,—I am a busy photographer, and am seriously inconvenienced by the slowness of the printing paper I have hitherto used. In my despair I turned to Eastman's gelatino-chloride, as it certainly seemed to have some advantages over the best albumenised paper, but I am rather disappointed with it. It certainly prints quickly, but, as far as I have gone, the advantages seem, in my hands, to end there. The prints tone unevenly, while the film is so delicate in manipulation that, if you mount the prints in the usual way, they stick together, and it is impossible to get them apart; as for burnishing after you have mounted them separately (a great waste of time), your work is all undone. Are there no means of easily working this paper, in order to get good and uniform results?—I am, yours, &c., C. D. V.

London, S.W., August 8, 1892.

[In our experience of the new Eastman paper, we have not met with the difficulties detailed by our correspondent; but having placed his communication before a professional photographer who, we are aware, is extensively and successfully working the new paper, we have received the following reply, which may assist "C. D. V." and others.—ED.]

"The great advantage of the chloride paper is, first, its quick printing qualities; second, the brilliant results obtained, the delicacy of tone, and fineness of definition, and, above all, permanency of image. Then there is the saving of time in manipulation; there is no need to wash before toning; the paper, not being soaked, does not take up so much hypo, and therefore the final washing is curtailed; and I have found that washing all night in running water, so long as alum has been used, does not soften the film nor make the paper pulpy.

"With Eastman's gelatino-chloride paper I find that I can get every shade of tone, from a brick red, through chocolate brown, purple, to almost black and white. It all depends on the length of time the prints are allowed to remain in the bath. A brilliant *glacé* or a matt surface can be obtained with the same paper.

"In the first place, the prints are squeegeed on to a ferrotype plate, which has been previously polished with a solution of three drachms of spermaceti wax dissolved in twenty ounces of benzine. This should be rubbed in, and then polished off with a dry duster. For matt surface I treat fine ground glass in the same way, and allow the prints to dry. I do not use talc or powdered French chalk, as it sometimes refuses to act. When mounting the highly glazed surface or the matt surface, I find it is best to use fine Scotch glue of a thin consistency. This, however, to the busy photographer would be a tedious process; but, if the following hints are acted on, there is no reason why any one should go back to albumen paper when chloride has the above advantages.

"*Toning.*—I do not insist that only one bath should be used; but photographers must please to remember that, whatever formula they make up, potash alum MUST be used. The neglect of this will throw all their careful work out, and failures will be the result. It is, however, only fair to say that, if a paper or a plate is to be given a proper and just trial, the formula issued by the makers should be used. Therefore I strongly recommend the following, which I have tried successfully:—

No. 1.

Hyposulphite of soda	20	ounces.
Alum potash	5	,,
Potassium sulphate	2	,,
Sodium sulphate (Glauber salts)	10	,,
Water (distilled)	160	,,

"First dissolve the hypo and alum in the water, then add the potassium sulphate and sodium sulphate. Allow to stand for two or three hours before using.

No. 2.

Gold chloride	15	grains.
Acetate of lead (sugar of lead)	64	,,
Water (distilled)	8	ounces.

"For use: No. 1, 8 ounces; No. 2, 1 ounce. Shake No. 2 well, and add to No. 1.

"*Washing.*—I omit the washing before toning, and find that two hours is sufficient afterwards.

"*Drying and Mounting.*—I proceed as indicated formerly, or lay prints face to back and drain the water out. This is where the non-use of alum will frustrate one's efforts. It is possible, however, to mount the prints damp, and for a mountant I use Field & Tuer's Stickphast. Rub down with a fluffless, chemically pure paper, or a soft sponge. I do not use a highly glazed paper or blotting paper to a gelatino-chloride print. The prints may be allowed to dry naturally, and mounted in the usual way.

"*Burnishing.*—The prints must not be burnished (hot burnisher) until they are thoroughly dry, and should be passed through straight and quickly, and not corner-way nor slowly. It is not necessary to have the burnisher quite so hot as formerly used for albumen. Gelatino-chloride prints do not require lubricating.

"A few general observations may here be made. The prints do not go back much in the toning, so time is saved because they need not be printed so deep as for albumen.

"The combined toning and fixing bath has been attacked, and the chemical question can be left for chemists to fight out. All I know is, that the results are perfect in practice, whatever the theory may be. It is, however, quite competent for your correspondent to be assured that the prints are absolutely fixed after two minutes' immersion in the bath. With Eastman's paper I find that blisters are unknown. It has been a generally expressed opinion that gelatino-chloride paper is the paper of the future, but so many hang back because they fancy it is not so easy to use, and will require a change in the routine of work."

A NEW DEVELOPER.

To the EDITOR.

SIR,—I have been told by a friend lately returned from Germany, that a new reducing agent has been discovered by a foreign chemist, which

will develop plates without the need of an alkaline accelerator being employed. As such a developer would be a boon to amateurs, may I ask you to be kind enough to tell me where it can be obtained, also price, &c., and much oblige?—I am, yours, &c., DEVELOPIST.

August 9, 1892.

[We are unable to give the particulars asked for in the last sentence of our correspondent's letter, but if he will turn to another part of the JOURNAL (p. 517), he will find that his information as to the new developer is correct.—ED.]

THE DECAY OF PROFESSIONAL PHOTOGRAPHY.

To the EDITOR.

SIR,—I read your editorial in last week's JOURNAL on the above with dismay, and surprise that your JOURNAL, running ostensibly in support of photography as a trade journal, should go out of its way to run a tilt at its chief supporters, and slate the profession generally. This is, to say the least of it, "bad form," and is not easily understood. Your remarks about the causes commonly assigned for depression in business being *bad trade, severe competition*, &c., are not wise. These are usually the cause of any depression. Photography being practically a luxury, is bound to suffer more or less in a time of depression, as the necessaries of life make first and often last demands upon the purse when money is tight, therefore photography has to stand aside and wait the advent of a more prosperous season. The remarks about the once-despised but not potent amateur are, to my thinking, far-fetched. In what is the amateur all-potent? In plate spoiling, I should say, and bringing them to the photographer with elaborate suggestions as to how they should be printed. Lads fifteen years of age, clerks in banks, and others having leisure time, and elated with having secured some sort of an image on a plate, immediately begin to instruct the professional, thus proving that "a little knowledge is a dangerous thing." Your remarks about a boy fifteen or sixteen years of age learning the business in a year are most absurd. Then, what have the twenty-five years' workers been doing, especially as they are still learning? They must either be complete duffers, or else your remarks won't hold water.

You say, What is to be learnt in the studio beside lighting, posing, exposure, and development? I reply, Nothing more than these four; but they take learning, and boys of fifteen don't know them, Mr. Editor. Then you go on to say that all, or nearly all, the work is "put out"—printing, retouching, enlarging, and even taking the negative. This is not the case with myself, and I can hardly think the picture true of the profession as a whole. I have had twenty-five years' practice, and been all through the wet-plate process, being in full swing with that before dry plates were brought in commercially at all. I speak disinterestedly on this matter of apprentices, not having an apprentice in the place at all, all my assistants being paid workers at current rates and have been with me some years; still, I think I should be a fit and proper person to teach an apprentice his business, if I had one. Why should a photographer not be a fit person to teach a lad his business? You put them down as a lot of footpads! under-the-weather sort of chaps! seeking whom and what they may devour in the shape of apprentices and premiums, and then, having secured them, not able or willing to teach anything in return! I don't think this is a true estimate of the great body of photographers, and I repudiate this view of them on their behalf. Then you say that, fortunately, the future of photography does not depend on the professional. Who does it depend on, then, may I ask? They are the practical exponents of the art, and the most interested people in it. Does it depend on cheesemongers, or the all-potent amateur? Speaking for myself, I know I have laboured conscientiously and vigorously to master photography in its various branches, and, when I have done with it, shall leave it better than I found it. If all of us work, not to get a living, but out of a sheer love for the art science we have taken up, I say that is just what the future of photography *does* depend on—the art, education, ability, and enthusiastic endeavour of its professors and workers.—I am, yours, &c.,

August 8, 1892. A PROFESSIONAL PHOTOGRAPHER.

[We congratulate our correspondent upon his non-mercenary devotion to photography, a sentiment which, were it more general, would have obviated the publication of the article that has so unaccountably stirred "A Professional Photographer's" ire. The object of that article was, as, indeed, our object always is, to point out opportunities for our professional friends to promote their own advancement. Were they invariably so well up in their art as "A Professional Photographer" claims to be, and just as competent to teach it to apprentices and students as he also wishes us to infer he is, we should, in recent times, not have had such innumerable pleas for the establishment of technical institutes, and it would not have been our unpleasant duty to draw attention to the frequent disqualifications of photographers as teachers and instructors. Of course, there are many exceptions to this rule; while there is one important qualification for business success in which we are happy to find photographers (with the exception of "A Professional Photographer") seldom deficient, and that is the useful art of politeness.—ED.]

EIKONOGEN FOR BROMIDE PAPER.

To the EDITOR.

SIR,—In using eikonogen for bromide paper, I find that I can seldom get the shadows other than of a blackish-brown colour, which gives an appearance of rustiness to the print. The formula I use is as follows:—

Eikonogen	4 grains	to each ounce of water.
Soda sulphite	20 ,,	
Potassium bromide	1 grain	
Soda carbonate	10 grains	

I notice that at a meeting of the Photographic Society, Mr. Clifton spoke very highly of an eikonogen formula by Mr. Cowan, with lithium carbonate. Would either of those gentlemen kindly give your readers the benefit of the formula, and say what advantage the lithium has over the other carbonates?—I am, yours, &c., G. G. DRUCE.

West Kensington, August 5, 1892.

LOSS OF DENSITY IN FIXING.

To the EDITOR.

SIR,—Mr. Benham and Mr. Albert Levy disagree with you in your proposition that a negative appears rather denser when wet than when dry. I was always under the impression that such was really the case, so that your correspondents' denial took me by surprise. Upon putting the matter to the test, in the only practicable way, that is by comparing the portion of a negative still wet with one that had dried, my impression and your statement were decidedly and unmistakably confirmed.

Perhaps my eyes are different in power to those of Mr. Benham and Mr. Levy; but, singular to relate, my wife and several friends (among them two amateur photographers) agreed with me on inspection that the wet parts of the negative were denser than the dry. Will Messrs. Benham and Levy oblige me by casting theory to the winds, and putting my experiment to the proof?—I am, yours, &c., A. C. MANNERS.

London, August 8, 1892.

"CUTTING THE SHADOWS."

To the EDITOR.

SIR,—My attention has been called to a paragraph in your report of the proceedings of the London and Provincial Association dealing with the question, "What is the meaning of 'cutting the shadows' in a plate?" The paragraph I particularly refer to is as follows:—"It appeared that the question referred to an editorial notice of the 'Barnet' plates by a contemporary, in the course of which pyro *soda* was said to 'cut the shadows.'"

Now, Sir, what your contemporary stated was, that I had said that pyro and ammonia cut the shadows (your report says pyro and soda); but, unfortunately, neither of you are correct. What I actually said was, that any good formula worked well with the "Barnet" plates, but I did not like sodium sulphite in combination with pyro and ammonia, as it tended to cut out the shadows (*i.e.*, leave them too bare). The "it" referred to was sulphite of soda (which your contemporary omitted), as in my experience a good, clean emulsion, such as the Barnet plate, does not require the assistance of sulphite of soda to clear the shadows (although it may be necessary with some makes of plates), and such a developer tends, with these plates, to leave the shadows too bare, or, in other words, cuts out the delicate detail in the shadows. Apologising for trespassing on your space,—I am, yours, &c., BIRT ACRES.

Clovelly Cottage, Barnet, N., August 9, 1892.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Wanted good cabinet portrait lens in exchange for whole-plate portrait lens.—Address, A. WILKINSON, Photographer, Bradford Road, Dewsbury.

Wanted three-inch compound slide rest for Lancaster's fifty shilling quarter-plate camera and leather case.—Address, "MERBLE," 61, Newman-street, W.

Exchange capital tricycle for battery of quarter-plate lenses, half-plate kit, or Aptus universal camera.—Address, W. P. WIENMAN, Painswick, Gloucestershire.

Will exchange Marion's *Retouching Book* (2s.) and *Ilford Manual* for the *Indispensable Handbook of the Optical Lantern*.—Address, LEMMANN, Photographer, Mold.

12×10 single lens, by Ross, eighteen-inch focus; exchange for four-inch portable symmetrical or Dallmeyer's four-inch wide-angle rectilinear.—Address, T. HADDOCK, 27, Chapel-street, Leigh, Lancashire.

Will exchange THE BRITISH JOURNAL OF PHOTOGRAPHY 1886 to 1891. Missing numbers are three numbers in January, one in April, three in May for 1886, month of February in 1887, two numbers in December, 1891. Exchange for materials for carbon process.—Address, W. C. BAX, Morden-street, Rochester, Kent.

Exchange 9½×9½ square bellows studio camera, four single slides and carriers, also half-plate Lancaster's Instantograph, three Tylar's metal double slides, and Lancaster's wide-angle landscape lens, for good whole-plate modern camera and three or four double backs.—Address, J. T. PICKLES, Lloyd Works, Hebden Bridge.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges" must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

Egmont Augustus Usherwood, Norwich.—*Photograph of Frederick Williams, late railway guard.*

William Harrison, Leeds.—*Photographs of the Hunslet Football Club, and of the following members: A. Goldthorpe; W. Golthorpe, J. Rathmell, and A. Goldthorpe, in a group.*

DR. L. GIOPPI (Milan).—The book has not reached us.

A. J.—Spot the printa in just the aame way as you would if they were on albumenised paper.

A. JAMES.—Probably your celluloid films "buckled" in the carriers, hence the inequality of the definition.

R. NICHOLS.—If the photographs are copyrighted, you can proceed for the recovery of penalties for the infringement.

E. MARTIN.—We should recommend you to apply to a picture dealer. The photograph is, we should say, an excellent one.

E. LIESEGANG (Düsseldorf).—Xylonite suitable for the purpose may be obtained of the British Xylonite Company, Homerton, London, E.

E. B.—Possibly the granularity would not appear with pyro soda. We have never experienced the trouble complained of with the plates you name.

H. WILKINS.—If lightness is such a great *desideratum*, why not have the stand made of bamboo? It is very rigid, and much lighter than either oak or ash.

W. A.—Quite right. Hydrofluoric acid cannot be kept in glass or porcelain vessels. For its storage, bottles of lead or gutta percha have to be employed.

D. J. W.—Pine will do quite well for an enlarging camera, but it will not prove so durable as one made of mahogany, particularly if it be subjected to rough usage.

A. NICHOLS.—Brilliant prints twenty years old, and still showing no signs of fading, are by no means "great curiosities." There are many nearly double that age which show little or no change.

GEL.-CHLOR.—You may be able to derive some assistance in your difficulties with the new gelatino-chloride paper by perusing the letters on the subject which appear in our correspondence columns this week.

M. D. (Birmingham).—If the dealer puts his name on an apparatus of foreign make, without an intimation that it was made abroad, so as to represent it being of his own manufacture, he certainly infringes the Trade Marks Act.

S. DAWSON.—About the best material for rendering paper photographs transparent, for colouring from the back, is paraffin. It is not so liable to discolour as varnish or resins. Beeswax is also good, but not so good as the paraffin.

C. W.—Orthochromatic plates ought to be better for photographing flowers than others not so treated. The greater part of the flower studies of Mr. H. Stevens were taken on ordinary plates. All Mr. and Mrs. Payne's were by the wet-collodion process.

T. ELLIOT.—1. What is known as "four-pound" lead will be quite thick enough to line a small water-cistern with. 2. Xylonite dishes should not be used for spirit, as that is a solvent of the material. 3. Probably only a rumour that has no foundation in fact.

BOWMAN says: "Will you give me a hint as to the use of mercuric chloride to obtain warm tones on bromide paper, or refer me to any source of information on the subject?"—See an article by Mr. Thomas Bedding on page 549 of the volume of the JOURNAL for last year.

SILENDO.—The picture was produced by an adaptation of the carbon process called chromotype, full particulars of which you will find in Hardwich & Taylor's *Photographic Chemistry*. The process is practically obsolete, although at one time it was extensively worked.

LEEDS.—The rain water caught from house pipes in large towns is usually far more impure than the ordinary tap supply. It certainly should not be used for any purpose for which distilled water is necessary. We believe you may attribute much of the trouble to the water employed in compounding the solutions.

ARC says he has a single landscape lens of twenty-five inches focus, and four and a half inches in diameter. The smallest stop is about three-quarters of an inch. He asks what size picture this ought to take.—With that size stop the lens, if a good one, should cover well an 18×15 plate, or, perhaps, one a little larger.

W. MAYS.—The converging perpendiculars are not due to any fault of the lens, but are caused by the camera being tilted and the swing back not being brought into use, or not sufficiently so. That form of lens will give perfectly straight lines when used in its entirety, but not, of course, when its components are employed as single lenses.

A.—If a photographer, or any one else, uses the Royal Arms, and styles himself "By appointment to Her Majesty," unless he holds the royal warrant, he renders himself liable to a heavy penalty. The mere fact that he has taken the Queen's portrait, when attending a ceremony with a number of other persons, does not entitle him to use the terms quoted.

A. MCANDREW asks if indiarubber paper is now used for double transfer carbon printing, as on making inquiry he is told that its use has been discontinued for many years. That is ao in thia country, but we believe it is still used at some places on the Continent. In England the method with rubbered paper has been quite superseded by the "flexible support."

LITHO.—It may be relied upon that the want of density in the negative is not due to the collodion. The brand mentioned is one of the best for the purpose. In all probability the bath is not in good condition, or the development is not carried far enough in the first instance. If there is not a good body of ailver in the image to begin with, it will be impossible to get an intense negative.

W. GOSS aska, if a ailver print be fully coloured in water colour, and the ailver image after a time fadea, the picture will be deteriorated—that is, will the fading show through the colour?—Yes, the fading will show; indeed, the picture would be spoilt. The fading will even show through oil colour. If the pictures are to be expensively finished, they ought to be printed either in carbon or platinum.

Q. E. M. S.—If the apparatus has been kept long enough in the damp to cause the glue to exude from the joints of the camera and dark slides, it will, we fear, be a job for a camera-maker. The best treatment we can suggest is to put the apparatua into a dry room, fully exposed to the atmosphere, so that it may dry slowly. In no case should it be subjected to heat, which would certainly cause the wood to warp.

R. COOKSON.—Yours is not an exceptional experience. When shellac is dissolved in spirit, it does not form a clear solution, but a muddy one, as described. If, however, the solution be allowed to stand undisturbed for a week or two, the thick portion will subside, when the clear may be decanted. Keeping it in a warm place will materially hasten the subsidence. It may be still further hastened by heating the solution.

E. R. C. asks how those elaborate gilt picture-frames which are frequently sold for gold ones are made. We believe they are moulded in the same manner as the gold ones, but, instead of being gilded with gold-leaf, Dutch metal is employed. They are then varnished with a colourless varnish. The cheaper kind of German bead is first coated with silver-leaf, and then lacquered. Both these frames discolour rapidly when the varnish perishes. Some, however, wear well for some few years.

R. FORTUNE asks: "1. What is the sensitometer speed of the 'Excelsior' and 'Nameless' plates? 2. Where can I obtain half and whole-plates to work from the one-hundredth of a second up to the two-hundredth with the 'Newman' shutter? if possible, give aensitometer number and price. 3. What is the price of oxgall, which is mixed with alcohol and used for enamelling? I do not see it in any of the catalogues I have at hand. 4. In the YEAR-BOOK there is a formula for delicate transparencies—pyro, citric acid, and water. Is this for chloride or bromide, and have you to add any other chemicals?"—1. The plates are unknown to us. 2. Most, if not all, rapid plates would work at those apeeds under favourable circumstances. 3. Any artists' colourman's catalogue contains the information. 4. Pyro, citric acid, and water will require the addition of an alkali for either chloride or bromide plates.

PHOTOGRAPHIC CLUB.—August 17, *Photographing Interiors.* 24. *Kallitype.* Saturday Outing, August 13, Waterlow Park. Meet at principal entrance at half-past two.

THE success which attended the lectures in connexion with the last Photographic Exhibition has decided the council of the Fine Arts Institute, Glasgow (where the exhibition was held) to give nightly, during September and the first week of October, a series of lectures illustrated by lime-light views. Arrangements have already been entered into with several popular lecturers, including Professor Young, Messrs. A. Rennie, G. G. Napier, G. Thompson, F. Clibborn, G. Patin, G. Mason, T. N. Armstrong, Rev. Thomas Somerville and others, and, probably, Mr. A. Pringle. Mr. Armstrong is assisting the Secretary of the Institute in arranging the scheme.

THE CONVENTION GROUP.

With this week's JOURNAL *we give a collotype reproduction, by Messrs. Thevoz & Co., of Geneva, of the group of members of the Photographic Convention of the United Kingdom, assembled at Edinburgh, July* 11–16 *last. The negative was taken by Mr. Alexander Ayton, jun., of Edinburgh, and, as our readers may judge by the reduced print, is a very fine one.*

Owing to the difficulty of identifying the large number of persons in the group, and in order to make it as complete as possible, we are obliged to defer the presentation of the Key until next week.

CONTENTS,

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1685. Vol. XXXIX.—AUGUST 19, 1892.

PURCHASING OIL-FREE METHYLATED SPIRIT.

We are now, by the kindness of a provincial correspondent, able to put our readers in possession of the routine to be observed in obtaining the old kind of methylated spirit, that is to say, without admixture with petroleum oil, in which way alone is it now purchasable in small quantities. It may be well to recapitulate the ordinary conditions of storage and sale. To obtain spirit of wine duty free, the Board of Inland Revenue permitted its sale when its potable condition was destroyed by the admixture of ten per cent. of impure wood naphtha. Retailers could sell it without a licence if they added shellac or other resin to it in a certain proportion, the resulting mixture being known as "finish." Last year, owing, it is stated, to these conditions being insufficient to prevent its being used as a beverage, it was further decreed that a further addition of mineral naphtha must be made to the spirit before selling it.

For varnishes any of these forms of spirit are not unsuitable, but "finish" is inapplicable when any purpose involving the addition of water is intended. While for all other ordinary requirements it has been considered that the mineral oil would render the spirit quite useless, as a matter of fact we have received few complaints as to ill effects occurring in actual practice; but, at the same time, there is no doubt that a strong desire to be able to procure the old-fashioned sort exists among photographers generally.

Our correspondent's first step was to send a messenger to the local Inland Revenue Office to obtain the necessary documents. The message was sent that it would be better to make a written application to that office. The letter was written, and a week or so afterwards the head of the office personally called upon the writer of the letter, and, in a most courteous manner, required a considerable amount of information: How much every year was likely to be wanted? what purposes it would be put to? where it would be kept? was there any communication with any establishment for the sale of spirits? was there a still on the premises? and a variety of other queries were put and answered. For a while no further action was taken, but a little over a month from the date of the first letter an official communication from Somerset House was received. It conveyed the Board's authority for our correspondent to "receive annually twenty gallons of ordinary methylated spirit for use in photographic purposes."

This letter was followed by another a few days afterwards from the local office, conveying the same information. Shortly after its receipt another urbane official made a personal call, and brought for signature a printed form called an entry paper, a document to give the authorities power to enter the premises whenever desired to inspect the spirit and the place in which it was stored. There had to be described the place of residence, the "rooms, places, vessels, or utensils intended to be used, the marks or numbers by which they are distinguished, and the purposes for which they are to be used." There was then handed to the would-be purchaser a book of blank forms for Requisitions for Methylated Spirit, and this book "must be produced when required for the inspection of any officer of Inland Revenue." It was further expressly pointed out that, "before a requisition is separated from its counterfoil, both must be properly filled up. Should a form be accidentally spoiled, it must not be separated, but preserved for the officer's inspection."

After the first issuing of the decree about the new spirit, it was necessary for the would-be purchaser of the old kind to find a security to be bound in a penalty for the due performance of the conditions by the purchaser, but this is now unnecessary. It will thus be seen that, though there is a certain necessary amount of red-tapism to be got through before the old kind of spirit can be purchased, it is after all very simple, and where five gallons of spirit can be taken at once there can be no doubt that the old form of spirit will be far preferable to the new. It can be used for all purposes that the latter is available for, and for many that it is not.

We must, however, in conclusion, give a few needful warnings. The purchaser, under such permissions as we have described, must not on any account, if any business friend requires any, sell any portion of his spirit. He must be careful not to have a still without permission, and on no account to try experiments in purifying the spirit; he must only store it in the prescribed room or rooms; and, above all, he must take care of all the papers in connexion with its purchase and receipt.

EXHIBITIONS—OLD AND NEW.

The tongue of rumour is busy with an alleged scheme for the promotion of a photographic exhibition to be held in London next spring or summer, and designed, it is hinted, to open an avenue for the peculiar aspirations of those who fail to find sufficient scope for them at the "old-fashioned" exhibition of the Photographic Society of Great Britain. If rumour speaks truly, and we have every reason in this case to believe that she does, we shall hail the projected venture with great pleasure, for the simple reason that, while photography itself will not improbably derive some appreciable if indirect gain therefrom, the exhibition which it will be set to rival is not in the least likely to sustain the smallest damage, but, on the other hand, stands, to our thinking, every chance of surviving

the rivalry, and of emerging from the friendly competition with a public esteem and reputation highly enhanced and confirmed.

We shall not seek on this occasion to look below the surface for the primary reasons which are said to be at the foundation of the new venture, since they are of far too personal and particular a nature to admit of discussion in these columns, but we shall risk the assumption that the guiding spirits of the affair are a number of esteemed and undoubtedly clever photographers, who differ from the vast majority of their fellow-artists in the focal treatment of their pictorial studies. We are aware that among a limited section of the outside critical public that treatment receives higher commendation than the old-fashioned and conventional but thoroughly logical superiority of definition, upon which, on the whole, photography has thus far contrived to sustain a creditable existence; but as we have before pointed out, it is difficult to estimate what degree of favour the "out-of-focus" school of photography will attract from the intelligent general public, who have hitherto derived their impressions and knowledge of the progressive capabilities of photography from, among others, the annual exhibitions of the Photographic Society of Great Britain. Considered from this point of view, the projected rival exhibition will be a most interesting experiment, the result of which will be highly instructive. If, however, the assumption upon which we are basing these remarks is incorrect, the *raison-d'être* of the scheme is difficult to discover.

In the art world, revolt against what is contemptuously but unreflectively styled conventionality is constantly breaking out. The Grosvenor Gallery was, if we remember aright, a species of protest against the policy of the Royal Academy, which displeased the rump of the pre-Raphaelite brotherhood and some of its impressionistic imitators and hangers-on. But the Grosvenor Gallery has had to close its doors, while the "conventional" establishment in Piccadilly still lives, a prosperous institution. We shall resist the temptation to draw any analogy, merely relying upon its obviousness to point a moral for those to whom it is of more immediate concern than ourselves.

We should be among the first to rejoice if the new exhibition, should it ever take practical shape, were an artistic, and—shall we add?—financial, success. Most photographic exhibitions suffer, we think, more or less from the facility with which they create a sensation of monotony in the minds of many who are not interested except as ordinary visitors. Be the walls never so well covered with clever photographs, among which are representative examples of the great variety of modern printing processes, we ask why in most cases little, or no attempt is made to widen the scope of the exhibition? Surely, for instance, touched and untouched negatives of the prints on the walls would be instructive to many. Again, why are opal pictures, enamels, pictures on silk and other fabrics, and examples of the numerous decorative uses to which photography may be placed, so frequently absent from exhibitions? How few, as a rule, are the examples of photo-mechanical work, and how is it that to-day, when photography is employed by science to a hundred times the extent of a dozen years ago, the examples of scientific photography generally shown are not more numerous now than then?

It appears to us that any new exhibition which proposes to depend for success merely upon a display of "wall" pictures, does not stand the rosiest chance of securing a remunerative share of public favour. Indeed, we may be permitted to complain that several of the old exhibitions are too prone to restrict their attractions to so few classes of work. We do not suppose that any such suggestions as these will be entertained by the promoters of the new exhibition, as their adoption would, of course, frighten away the critical gentlemen upon whose good opinions such high store is placed; but they are, we think, worthy of the attention of the managers of those exhibitions in London and elsewhere which have, up to the present, not unsatisfactorily filled the office of showing the world what photography is and can do. In fine, not enough encouragement is given by exhibition committees to many branches of photography which are capable of supplying most attractive and instructive exhibits.

THE FERROUS OXALATE DEVELOPER.

II.

The green double salt, mentioned in our previous article, forms an important item in the process of recovery of the more valuable constituents of the spent developer. Starting with a solution made on the principle of Messrs. Carey Lea and Willis, we need only refer to the equation given in last week's number to show that the result of the complete oxidation of the developer, whether by use or by age, is the production of this salt together with the precipitation of a portion of the iron in the form of oxide; and that practically the whole of the constituents that are worth the trouble may be recovered by carefully collecting and suitably treating the crystalline residue after freeing it from the adherent ferric hydrate.

In the case, then, of a spent developer, or one that is so far exhausted as to be practically useless except as a restrainer—a purpose which it serves very well—the first thing to be done is to collect the green crystals of potassio-ferric oxalate already formed, and then to expose freely the remaining solution to the atmosphere in order to ensure its complete oxidation, the second crop of crystals being then collected and added to the others. For this purpose the solution should be poured out into a glass or porcelain dish, and left in a warm, dark place, under a light covering of paper or similar material, to protect it from dust without interfering with the free circulation of the air about its surface. It is probable that the end might be gained in a more rapid manner by the use of oxidising agents, but we consider it in every way preferable to avoid the introduction of foreign substances which would prove difficult to eliminate afterwards.

Before proceeding farther we may say a few words on the composition and properties of the crystals. If the equation given last week be analysed, it will be noticed that the ferrous and ferric double salts differ only in the proportion of iron contained in them, the latter consequently, if the elements be rearranged, being found to contain an atom of free oxalate acid, while the proportion of oxalate of potash to ferrous oxalate is fifty per cent. greater. In order to reconvert the solution of the crystals into an active developer, it is therefore necessary to add an atom of iron, which, being first converted by the free acid into oxalate of iron, is then taken into solution by the excess of potassic oxalate.

The simplest plan of restoration would therefore seem to be that just recommended by the I. W. Swan, of boiling the spent solution, or the solution of the green crystals, with metallic iron, though in practice some uncertainty of result arises, possibly from the great tendency to oxidation of the hot solution. Still, the process is a practical one, and we may

therefore describe it. Let the crystals be separated from the precipitated ferric hydrate, and if necessary washed in a small quantity of cold water. They may then be further purified by recrystallisation from the smallest possible quantity of boiling water, the great difference between their solubility in cold and hot water respectively rendering this an easy matter. The washing water and mother liquors are to be added to the original solution, which still contains more or less potassic oxalate, the only ingredient worth saving.

The purified crystals are then dissolved in a volume of hot water, equal to about three-fourths of the original solution, in a glass-boiling flask into which a coil of bright iron wire has been introduced, and a gentle heat kept up. Gradually the almost colourless solution assumes a ruddy tint from the formation of the potassio-ferrous oxalate, and eventually, if the quantity of water used is not too great, it will acquire the deep ruby colour of the freshly mixed developer. If an excessive quantity of water be employed, the colour will be lighter, and it will be necessary to reinforce it with additions of potassium and ferrous oxalates. If, on the other hand, too little water be used, a portion of the compound iron salt will be thrown down and probably decomposed; but if this should occur—as the decomposition only consists in the precipitation of ferric hydrate and re-formation of the potassio-ferric oxalate—a continuation of the process with a larger volume of water will set matters right. There is almost invariably a certain amount of muddiness in the solution produced by the slight oxidation of the ferrous salt under the influence of heat; indeed, this occurs even in forming a new developer, and disappears if the oxide is allowed to subside. The conversion may be allowed to take place in the cold, but the process is then a very slow one.

The operation of reduction should be conducted by gaslight or in a subdued diffused daylight, owing to the fact that the solution is sensitive to light, and complications might be introduced if a strong light were allowed to act upon it. This brings us to a second method of restoration, which for various reasons we prefer to the one just described.

The solution of potassio-ferric oxalate, like that of plain ferric oxalate and other organic ferric salts, is, as we have said, sensitive to light, suffering reduction to the ferrous state with liberation of oxalic acid, which splits up into carbonic anhydride and escapes, while ferrous oxalate is precipitated. The reaction is shown in the following equation:—

$$\underset{\text{2 atoms.}}{2\,K_3Fe(C_2O_4)^3} = \underset{\text{2 atoms.}}{2\,FeC_2O_4} + \underset{\text{3 atoms.}}{3\,K_2C_2O_4} + \underset{\text{2 atoms.}}{2\,CO_2}.$$

Potassio-ferric oxalate = Ferrous oxalate + Potassic oxalate + Carbonic anhydride.

This is the result if the solution at normal temperature be exposed to a strong light, and the fact has been utilised in the attempt to construct actinometers which should measure the value of the light by the quantity of carbonic acid gas given off. None of them, however, have proved practically useful, as the evolution of the gas continues for some time after the action of the light has ceased. Ferric and uranic oxalates are the salts that have been chiefly employed, and their ready solubility in water enables them to form very sensitive solution. The solution of potassio-ferric oxalate in cold water is, however, so comparatively dilute that the process of reduction is very slow, and the potassic oxalate formed is too weak to exert any solvent action on the ferrous oxalate formed, which is consequently precipitated, leaving the solution clear and colourless.

But, if a hot concentrated solution of the green crystals be exposed to sunlight or strong diffused light, the action is very rapid, and the original yellow tint of the liquid gradually deepens until it reaches a pure ruby. In this case, as in the last, the proportion of water employed should be regulated according to the quantity of the original solution, otherwise a portion of the iron will be precipitated in a partially oxidised state.

When the solution has become perfectly colourless, and no further precipitate of yellow ferrous oxalate occurs in the case of the cold solution, or when the colour ceases to deepen in the case of the hot, the action is complete. The cold treatment is of no practical value, as the volume of liquid is too great for any useful purpose, and, as already stated, the small proportion of ferrous oxalate is thrown down instead of being taken into solution. In the other case, an active developer is formed, though it is not at its full strength, since it contains an excess of potassic oxalate, or, more correctly speaking, there is a deficiency of ferrous oxalate. Before allowing the solution to cool, therefore, some ferrous oxalate should be added, and time allowed for the free potassic oxalate to become saturated; or, if preferred, a solution of ferrous sulphate may be cautiously added, until a precipitate just begins to form, though this will produce a less energetic solution than the other.

Thus far the economically inclined photographer will find all tolerably plain sailing, the manipulations easy, and the result perhaps worth the trouble if the system of saving the solutions be carefully followed out; but, if he is desirous of proceeding any farther to recover the potassium salts from the muddy solution whence came the crystals, his troubles will begin, and he must be prepared to perform a series of operations requiring a great deal of care and skill in chemical manipulation, for which he will secure but a poor return. We may just sketch the course to be followed, though we doubt whether it can be made remunerative, even on the most extensive scale.

The first operation in this case must be to filter the liquid clear of the sediment which, in the case of an unused developer, will consist almost, if not wholly, of ferric oxide or hydrate. In the case of a developer that has been in use, there will be present in the sediment also a certain amount of ferric oxybromide, dependent upon the amount of use to which it has been subjected and the length of time kept. The sediment, however composed, may be at once thrown away as valueless.

The remaining solution, which will vary in colour from a dirty brownish red to a decided yellow, according to circumstances, will now contain chiefly potassio-ferric oxalate, with, perhaps, a little unoxidised ferrous salt, together with, in the case of a used solution, some ferrous or ferric bromide. Both the latter salts are most probably formed by the hydrobromic acid derived from the sensitive films, the first being gradually oxidised and converted into oxybromide, while, in the form of ferrous bromide, it communicates a yellow tinge to the solution, the ferric salt contributing a brown colour. In the case of a developer made by mixing solutions of ferrous sulphate and potassic oxalate, there will also be present the ferrous sulphate produced by double decomposition.

The next operation is the elimination of the remainder of the iron which is totally useless. This is effected by the cautious addition of solution of potassium hydrate, by means of which the iron is thrown down in the form of ferric hydrate, potassium oxalate being left in solution. At the same time, any bromide of iron present is converted into potassium bromide with separation of ferrous hydrate, and the solution becomes colourless or nearly so.

Next we have to deal with the soluble bromide present, which, if allowed to remain, would play the part of restrainer whether wanted or not. This can be eliminated by shaking up the solution with excess of silver oxalate when the bromine goes to the silver to form silver bromide, and oxalate of potash is again formed. As oxalate of silver is very slightly soluble in cold water, a minute trace may remain in solution, but this will be instantly reduced on the addition of the ferrous salt in the process of preparing the developer.

Lastly, we have to eliminate the sulphuric acid present in the form of sulphate of potash, which, though but a mild restrainer, cannot be allowed to accumulate indefinitely, as would be the case after repeated rejuvenations of the solution. This is got rid of by means of barium oxalate, employed in the same manner as the silver oxalate, barium sulphate and potassic oxalate being formed by double decomposition.

If these various operations have been well and carefully performed, we shall now have a solution containing only potassium oxalate and accidental impurities from which the salt may be separated by crystallisation, when, if the result satisfy the operator, it will be satisfactory, though, as already said, we do not expect it.

On a large scale and systematically worked, the first part of the process—the reduction of the green crystals—may, no doubt, be profitably carried out; but, so far as we can see, except as an interesting experiment, the latter operations are useless and pecuniarily unprofitable.

The Price of Silver.—A few weeks back reference was made to the extraordinary low price of metallic silver. Since then its value has further declined, again "beating the record." It was quoted on Friday last at 37⅞*d.* per ounce. Some years ago the metal was worth over 60*d.* per ounce, and at that time eighty and ninety-grain baths were in vogue for sensitising paper upon. From this it will be seen the production of photographs was more costly then than now. But, then, *cartes-de-visite* were not done at half-a-crown a dozen.

Science and Art Report.—In the annual report just issued, on the subject of chemistry, the examiners complain that only comparatively few candidates possess any real knowledge of chemical principles, or show accurate observation of facts. The conclusion arrived at by the examiners is that the students are left very much to themselves by the teachers, and therefore have to work at their text-books without assistance, and in many instances without properly understanding them. Reform is certainly needed, if this be the case, in teaching practical chemistry, and the department should see to it, as it is liberally supplied with funds. In some instances we fear that the teachers have only a superficial knowledge of the subject themselves. If this be so, how can it be expected that they can impart sound tuition to others? Many of the certificates now obtained are the result of cramming and coaching, rather than that of well-grounded knowledge.

Manufacturers' Reputation.—In advertisements, when anything is to be disposed of, the name of the maker is generally quoted as a guarantee of its quality—that is, if the maker happens to be one of renown. This is done quite regardless as to the treatment it may have endured since it left his hands. Every one knows that cameras, and suchlike apparatus, suffer deterioration by use; but all may not be aware that lenses may do the same. A lens, by a first-class optician, may, after a few years' use in some hands, be no better as a photographic tool than one by a second or third-rate maker. Therefore too much reliance must not be placed on makers' names. Indeed, with some second-hand apparatus, their reputation may suffer. The most amusing instance of trading on a manufacturer's reputation that has come under our notice was when, in reply to an offer in our "Exchange Column," a number of lantern slides were offered, and, as a guarantee of their excellence, it was stated that they were all made on Blank's plates.

Foreign Reproductions.—Reference has more than once recently been made to the fact that a very large proportion of the photogravure reproductions of English pictures are made on the Continent, and asking the reason why. It is rumoured that, at the closing of the Royal Academy Exhibition, several of the best works were dispatched abroad to be reproduced by photogravure or other processes. Should the rumour prove correct, it would certainly seem to be a reproach on British photographic engravers. One thing seems pretty certain, which is that the photographic reproduction of works of art is made more a speciality of abroad than it is here. One seldom sees in the shop windows photographs, silver prints of the scrap type, of English paintings, though they are full of copies of foreign ones. Although these copies are sold at a very low rate, every one who examines them critically must be forcibly impressed with their technical excellence, and the way in which the different colours of the original are translated into monochrome. Indeed, it is almost difficult to conceive that many of them are copies of paintings. Of course, the more perfect the negative the better will be the photogravure made from it.

Collotype Views.—For some years past it has been a matter of surprise to many, ourselves amongst the number, that the collotype process has not been more extensively employed than it has in the production of views of seaside places and other holiday resorts. We are fully aware that the process has been utilised for this kind of work, but usually under its most unfavourable aspects—that is, as regards quality. A high-class collotype is in every way equal, if indeed it is not superior, to the finest silver print. At the same time, it has the undoubted advantage of permanence—no mean advantage to those publishers who supply the trade "on sale or return." Collotypes, such as will compare with the best silver prints, cannot be produced at a low rate, but they need not cost more than the silver. The usual run of collotype for this class of subject is generally of a very low type, and the process is not shown to its best advantage. There are to be seen at the present time, in the shop windows, views of London mounted in optical contact with glass with bevelled edges—"opalines," as they are termed—made by this method. Now, if there is a way by which a collotype can be shown to a disadvantage, it is when it is treated in this fashion. If the print be of a mediocre character, by this treatment its vigour is reduced, while its granularity is apparently exaggerated. These remarks suggested themselves when looking at some of the London views alluded to, bearing the initials of a well-known publishing firm, which we can only assume are piracies of their work, as we feel assured they would not issue pictures of such quality.

Practice v. Theory.—Much has been said of late in the pages of this and other photographic journals on the subject of technical education. Now, there is no question that the man who has a good theoretical knowledge of the work he is engaged upon possesses, or ought to do, material advantages over the one who only works, so to speak, by rule of thumb. It has been said, with regard to apprentices, that there are very few masters who are themselves competent to teach the business for which they have received a premium. That this is the fact with some who take apprentices, or, to use the modern term, "articled pupils," cannot be denied for a moment—that is, if we take photography even in only a few of its many phases. On some parts of the Continent there are schools where the photographer may acquire a theoretical knowledge of his art. But do those who avail themselves of them turn out better workmen than those who do not? They should do, though some Continental employers say that they do not, until they have unlearnt a great deal of what they have been taught. The principal of a large photo-mechanical establishment on the Con-

tinent remarked to us, some little time ago, anent this subject, Where is the teacher in any of the technical schools who can himself produce collotypes, or engraved plates, or even negatives, equal to the experienced operators to be found in every establishment? adding that the majority of these know comparatively very little of theory, though they are sure of their work in practice. Still, as we have said before, a theoretical knowledge should be of value when combined with practical experience. But, if the teachers themselves cannot produce the best of work in practice, how, it may be asked, can they instruct others to do so?

CELLULOID FILMS.

Your answer to a correspondent as to the "buckling" of cut celluloid films, and the consequent loss of definition of the image, would, I should say, serve as a reply to a question which I myself might put before you with reference to the mysterious manner in which, despite the most careful focussing, some parts of my negatives on cut films often unaccountably approximate to an unwelcome furziness, while, on the contrary, other negatives exposed under similar circumstances, and during the same day or outing, are all that can be desired as regards general definition. Two years ago, when, on taking up cut celluloid films in place of glass plates, I met with this trouble, I was inclined to ascribe it to an optical cause; but the simple experiment of equalising the conditions of working as regards aperture and focus showed me that my conclusion was wrong.

This difficulty of getting uniformity of good definition with cut celluloid films is such a frequent one, not only with myself, but, as I am aware, with very many others who are working them, that I am induced to draw attention to what I consider their principal and almost fatal defect, in the hope that means will ultimately be found to remedy it, and thus prevent them (as seems to me probable) being abandoned by good workers. The economical and extrinsic advantages of cut celluloid films over glass plates are so well known and have so often been pointed out and admitted that it is quite unnecessary to mention them; but, in view of those advantages, it is all the more to be regretted that they are likely to be outweighed by one disadvantage which is a little difficult to remove.

I have, I think, used most, if not all, the film-carriers in present use, and the conclusion I have come to is that, for unvarying efficiency, they leave something to be desired. I have succeeded admirably with them at times, but my observation goes to show that success hinges to a great extent more upon the inter-relation of the film with the carrier than of the capacity of the latter to stand a variety of demands which are likely to be made upon it. An ordinary dark slide, made full in its measurements, will take a great number of glass plates of varying thicknesses and accuracy of cut. The fault of most film-carriers is, I find, that they are too accurately cut; and thus, if the film itself is also cut full, it is impossible to fit it in without considerable pressure, which is fatal to its "planularity." The knife or the scissors have then to be used, which is a nuisance.

Again, the tendency of all films, thick or thin, is to "curl in" with the coating, a property peculiarly liable to be influenced by temperature and other conditions. I find that this tendency is often not destroyed by the film-carrier, so that the film is not held in a perfectly plane position, hence it presents a concave surface to the lens. Theoretically I suppose, with an objective having curvature of the field, this would not be a disadvantage; practically, I find that the concavity is so considerable that it is impossible, no matter to what extent I stop down, to get universally good and even definition.

Of course I am here speaking of occasional experiences only. These are, however, so frequent as to seriously reduce the advantages of the use of cut celluloid films. Sometimes these are convex towards the lens, and then, in addition to the centre of the picture being out of focus, scratches from the shutter of the dark slide make their appearance on the film. I feel sure that any contrivance for holding these films, thick or thin, always plane under any circumstances, would be a great success. My experience of commercial film-carriers is that they generally fail in that regard, and a further drawback to their use is that they themselves usually buckle and bend on the smallest provocation.

JAMES R. HOPWOOD, Ph.D.

CONVENTION JOTTINGS.—IV.

A Run through Some of the Scotch Studios.

M. & T. SCOTT (West Saville-terrace, Edinburgh).

WHEN in Edinburgh, we paid a visit to the new photographic works of Messrs. M. & T. Scott. At the beginning of this year we made a notice of this place as a novelty when it was opened. Since then it has been completed, and we found it in full working order. We use the term photographic works advisedly, as the premises at West Saville-terrace are specially constructed for turning out large quantities of work, and that for the trade only.

Mr. Scott informed us that they had got their arrangements so complete, that they could turn out a plain enlargement and send it on to their customer on the same day that they received the negative—when such haste is demanded of them—but in ordinary circumstances four days are about the usual time to make, mount, spot, and send off an ordinary enlargement, from the time at which the negative is received.

When high-class work is required, however—and that is a special feature in their business—it takes fourteen days to finish and supply pictures of this class. One of the departments just introduced into the business is to undertake the finishing of photographers' own work, so that any photographer can send on his plain enlargements, and the Messrs. Scott will work them up at any price stipulated.

The arrangements and staff are so complete—this we doubt not—that engagements will be kept and orders sent out up to time in any department.

To convey some idea of the extent of the place and its appointments, we made the following jottings:—The ground occupied is about a third of an acre. The buildings on it cover 500 square yards. The enlarging and dark rooms are large, airy, and well appointed. The enlarging room is thirty feet by twenty feet. The enlarging camera is the usual—travelling on rails—pattern, with reflectors outside. For carbon work they have swing-covered dipping baths, large enough to take in a 60-inch plate. These baths and camera—and general apparatus in this well-appointed room—looked like a gathering of old familiar friends, belonging to the time when carbon, and nothing but carbon, was all the rage, before bromide and platinotype had come to the front.

All the sinks throughout are made of teak wood, and some of them large enough for the development of the extra-sized plates. In one section of the sinks we observed a very good arrangement, there being two outlets, one for the saving of the residue, and the other to carry away the waste water. All the pipes are glass-coated. The doors of the dark and enlarging rooms run on rails, and move along the surface of the wall; a heavy curtain is hung inside each to exclude all light. In one of these rooms they have a hot-water tank fitted, and, to utilise the space into which it is built, they have squared it up, thus forming a press, in which negatives, &c., can be quickly dried. The hot-water apparatus for supplying the establishment with hot water possesses the united advantages of doing a great deal well, and that at a very small cost. The boiler is a Cook's Star Boiler, with a circulating tank for sixty gallons. It produces hot water in twenty minutes, and continues all day at a constant, steady heat. You can have the water boiling if you so desire it, and Mr. Scott told us that, for an outlay of some twelve pounds, the whole thing was supplied and set up.

The studio, which is constructed and used principally for copying, has a double-ridged roof, so that it may be used as one, or divided into two studios, when necessary; the size of room is thirty by twenty-eight feet. The blinds for arranging the light are framed and run in grooves; there is a set of three grooves, and each fitted with blinds, so that any light, and any quantity of light, can be obtained at will. The arrangement works well, and seemed to us very complete.

The artist's rooms, printing rooms, and offices are all constructed for the meeting of any reasonable extension or requirements, and, in case of having to extend in any given way, the partitions are all composed of lath and plaster, so that at any time they can be removed without difficulty.

The Messrs. Scott's work, both artistic and plain, is so well known to the trade, that a passing comment is all that is necessary on that

point. The finished platinotypes in their place were many, and bearing the stamp of artistic feeling and careful handling. The demand for carbons seems large, both in engraving black and brown. Bromide work seems also to be gaining ground with them. We saw an etched negative and proofs from its very clever production turned out on the premises. We have seen the same class of work from America; and this sample we considered quite up to the American work.

We were shown some untouched enlargement views and groups, twenty-four inch, made from carbon negatives, as fine in finish as small work; and samples of opals as large as thirty-six inches; also pictures in carbon on ivory.

The professional who requires it can have all kinds of enlarging work produced here, and, as the proprietors hold, in the shortest possible time, whether plain, in black or white, water colour or monochrome.

Messrs. Tunny & Co. (13, Maitland-street and 19, Salisbury-place, Edinburgh).

We visited J. G. Tunny and Co.'s places, situated at 13, Maitland-street, at the west end of the city, and 19, Salisbury-place, Newington. These businesses are now carried on under the proprietorship and management of Mr. J. H. Balmain, who for some years previous to Mr. Tunny's death held the active management of the entire business, Mr. Tunny being laid aside from active work by lingering illness for a considerable time previous to his death in 1887.

In Maitland-street, which is the principal studio of the two, the entrance-hall and show-rooms are well and profusely decorated by all the various classes of work produced by the newest processes up to date. We found Mr. Balmain standing out far beyond the usual position of the ordinary artistic photographer, having embraced, and now working, some of the more complicated processes commercially.

In this business vitrified enamels are now a department of some considerable importance, and one that continues to grow. This is a natural consequence, seeing one of the first and best enamellers has retired from business, viz., Mr. A. L. Henderson, and the enamels produced by Mr. Balmain being of such a fine quality that the demand for these pictures will naturally come his way. His exhibits in this class of work have taken many awards, and the profession who visit our exhibitions have had many opportunities of seeing the fine quality of these enamel productions. Mr. Balmain is also an adept in *photo-gravure* work, which he undertakes and produces commercially for the trade. We have, on previous occasions, commented on the high state of proficiency Mr. Balmain has attained in this by no means easy branch of photography; but, as most of the profession has handled his work at one time or other, it is familiar to most.

In photo-lithography he also takes a part, and that one of the most important. He does not go to the length of producing the photo-lithographs, but from the originals he supplies the transfer to the printer ready to lay on the stone. With all these irons in the fire, so to speak, you can quite understand that Mr. Balmain is a very busy man.

In a talk which we had about printing-out paper, with which for some months back Mr. Balmain has been making a series of experiments, "For permanency the collodio-chloride coated paper is the best." Why so? we asked. "Well, you know, I find it much easier washed than gelatine, and I believe ever so much easier freed from hypo."

He brought some samples of collodio-chloride paper prints which he put into the frames in April to test their permanency, covering up one part of the print and leaving the other exposed in the usual way. When bringing them, he told us that he had not looked at them since the beginning of July, and at that time they had not changed a bit, keeping the full rich purple tone all over; but on opening the frames before us—alas!—all the purples had gone out of the exposed parts, leaving the pictures half purple, half brown. The brown, of course, was quite vigorous, looking more like a change in tone than fading.

"We will have to do a little more experimenting," said Mr. Balmain, as he laid the frame aside.

Pictures on opals are one of the prominent features in this business. Both Maitland-street and Salisbury-place studios are well known for the artistic class of work produced.

Mr. Tunny's was a name familiar as the art-science itself since the early days of photography. That the late Mr. Tunny stood during his valued career in the first rank of workers and investigators is a fact well known to all the practical photographic world, and that Mr. Balmain follows in the footsteps of his predecessor and keeps steadily moving ahead we feel assured, and we doubt not but the result of his labours will be profitable.

PHOTOGRAVURE.*

Relief.

Photogravure has now strangely invaded the letterpress department. It is one of the most curious and also most attractive marks of progress to see this thing—for the many blocks in half-tone now made are really photogravure plates in negative form—giving smooth places for black, and rough for light, instead of the reverse; but physically the difference is slight. (Mr. Dawson here exhibited four prints on one sheet, two being on a copperplate, and two on letterpress, remarking that the little plates in the various art *brochures* now so popular were all identical with photogravure plates, even to a large degree physically. There were differences, but they were slight.) It still remains to be noted that all the previous rules as to detail and transparency must apply, there can be no hard, flinty uniformity in the tint if it is to be approved by careful judges. Of course, some printing by machine is much rougher than others, and always must be; but it will not alter the proposition. It thus follows that the hard, square, crossed tint, however neat and regular, must be superseded sooner or later; indeed, regular mechanical work must give place to sympathetic rendering. Of course, this lies in the future, but it presses already, and has pressed; all artists say, "I hate that square grain," and a publisher will say, "I hate it too, but, if it must be there, let it be too fine for me to see it."

It should thus be borne in mind that when worked with that special view various methods hitherto employed for making an intaglio plate are suitable for the making of a relief photogravure. The vast bulk of this work is done by the old process of Niepce without and variation, by printing into a thin layer of bitumen, developing, any biting out with several stoppings. In France intaglio plates are constantly produced in this way. There is a large republished series of Albert Dürer, and they are all done in that way; they are bitten through a thin film of bitumen, and to make them deeper a man goes over them with a graver. The Pretsch process is a simple swelled gelatine surface. It has the advantage of not having pigment in the gelatine. These (shown) are Pretsch plates. Pretsch himself died long ago, and, so far as I am aware, no one has ever worked the process but myself. They can be printed in relief as well as in intaglio. Another way is by the Klic process, which renders most of the tints sweetly and consecutively, but is rather fine in the grain, and wants very careful rebiting to produce a printing block. And the worst part of rebiting, however skilful, is the necessary stopping out, which will always show itself. It is the want of a real, true, good method of photogravure in relief which keeps back its employment for scientific work where it is not lawful to touch with the hand to help out any matter of detail. If a man brings a scientific subject, he wants it correct, he does not want a sight of handwork on it, it would destroy its value. In anatomical plates it is impossible to have a method that demands the help of the hand. Of course, there is a difference in *demanding* the help of the hand, and having a little now and then occasionally; but I do not despair of arriving at this point of perfect reproduction in relief where management and skill can be made to supersede any mere hand work.

Colour.

Printing in colour shall conclude my rather vagrant paper, but there is a strong affection in the English mind for colour in prints, and from the earliest days of printing this has been observable. The missals which the monks were given to illuminating were followed by early printed books with the printed illuminations coloured by hand.

By the plate method colour is most suited to the lighter class of subjects. As the tint gets darker, the colour is found to be unable to give the required depth and power unless the plate is correspondingly deep. It, however, remains that the photogravure intaglio plate is the sweetest method yet known for printing in colours. Sometimes a water-colour drawing comes out so perfectly that you really cannot tell the copy by the side of it, and, when it is known that this coloured

* Concluded from page 524.

copy is a production of the press capable of multiplication, the result is all the more surprising. This way of colour printing lends itself to very subtle blendings of tint, such as are quite unknown to other modes; but, although producible in number, they are not very easy to do excellently well, and it is very usual to have to go over them afterwards with water colour. Consequently they are valuable, and, as prints go, rather scarce; but they are well worth producing, for the simple reason that the photogravure gives us the artist's touch, and this adds the charm of colour, thus bringing us very near to the artist. And, as I began, so I conclude, with the keynote that nearness to the artist is the most worthy aim of all reproductive methods. When water colour in its light touches is produced, it still remains to produce oil colour in its power, and very lovely I feel it will be to see this happy result.

It may be asked of me if I see any way of printing naturally reproduced plates with nature's selected tints. There was a method years ago for doing parcel plates in three or more colours by extracting them from an already prepared plate engraved in the ordinary way. There would be a mezzotint plate, and the areas of green and blue, and so on, were mapped out. Then you would electro copies, and scrape out from one what was not wanted for blue, from another what was not wanted for red, from a third what was not wanted for yellow. The consequence was, that by printing in careful register you got a very decent colour result, and one of my copperplate printers once used to print them. They were very nice at times, but, of course, entail three or four printings, and register in copperplate is a very difficult business. The process was patented, and some old printers still living have printed them. The paper was good and strong, so as to print three or four times in the copperplate press for the various colours without expanding and destroying register. Now, the nature-selected tints will depend on their results upon the limitation of this old, old process. I do not see how there is any way of inking a plate by an automatic method, and of course it must be by the medium of printing ink that the thing must be done. I do not see any way of inking a plate in nature's colours. And, on the whole, I incline towards making a nature monochrome plate and inking it in to taste. It must be remembered that by parcel or register printing on the copperplate press the delightful plate mark and broad margin are impossible, but by colour printing as above described these are preserved.

I must here conclude, but would in doing so throw out a hint that a fair history of the whole of the photogravure processes would form an attractive subject for such a Society as this, especially if small examples could be given from each. I think examples from the earliest days ought as soon as possible to be got together in a proper form, either as a single album deposited at the British Museum, or multiplied and distributed in the usual way.

[At the conclusion of the lecture, Mr. Dawson handed round examples of various processes of photogravure, and the Chairman remarked that the lecturer was so familiar with the different methods that he had referred to them simply as "the so-and-so process," but probably there were many gentlemen present who would be glad of details.

Mr. Dawson thereupon remarked, that all photogravure methods were based upon the autotype process, the Pretsch process being an exception. The Waterhouse method consisted in covering the tissue, when in a state of soft jelly, with sand or ground glass, which produced little notches over the entire surface. When dry, the business was to get the sand off again, and that was a business, for, of course, it was glued on, but the method he had adopted was very simple. He put the sand or glass into a ladle, together with a little knob of stearine or spermaceti, and heated the whole, by which means each particle of sand or glass became coated with the stearine or spermaceti, and, when put on the tissue and dried, could be easily rubbed off. Sometimes it would stick; but, as a rule, it all came away, leaving granulation on the surface. The fault was, of course, that it went up and down too much, and held as much ink in one place as in another. Then, there was the perforated method—his own. Before the tissue was placed under the negative, he rolled a mixture of tallow and stiff oil all over it, and then powdered it all over with bronze powder. In printing, the light only got through in the little cavities (shown by diagram), and it developed in little knobs—big knobs and little knobs—producing what he called a perforated mould. The great difficulty was that the picture could not be very well seen on the plate, the little bright remainders were so glittering. The great charm of the Klic method was that the details were clearly visible upon the plate. It was most important that there should be a healthy grain in the plate, and that the details should be clearly visible for working up. The large pictures exhibited were all done by what was called the Goupil method, although it was invented by Mr. Woodbury—an Englishman—and was an English method. He hoped that would not be forgotten. The process was kept strictly secret, but he believed it consisted in the preparation of a pigmented gelatine tissue over-saturated with soluble lumps of some hard salt. After printing, these lumps were dissolved out, leaving the picture like a sponge on the plate. It was undoubtedly the finest method known, and he was sorry it went abroad and that it was concealed. He also drew diagrams on the blackboard to explain the working of the Klic process.]

A. Dawson.

ADVANCED PHOTOGRAPHIC WORK FOR AMATEURS.

VII.

Perhaps, within the whole range of photographic practice, there is no more attractive style of printing to those intimately associated with, or who are outside the pale of, photographic knowledge than that of vignetting.

An operator who knows well his business will, at the outset—especially in the case of portraiture—select only such backgrounds as will lend themselves more particularly to this especial style of printing (and, as a rule, those of a light tint are best suited for such). But there are, unfortunately too often, cases where copies have to be made from prints, or where portraits have to be abstracted from groups in negatives under circumstances where the original backgrounds are not in any way suitable for vignetting, and therefore it frequently devolves upon a worker to make the necessary alterations upon such prints or negatives as will permit of their throwing off pleasing results in vignette form.

A very common case is when some figure forms part of a group, and which it is desired should be abstracted, either with the view of printing singly such portrait in *carte-de-visite*, cabinet, or other similar, or of slightly enlarged size. Very seldom indeed will such cases be found to have suitable backgrounds, and in nine cases out of ten, on the contrary, they will most likely be almost certain to offer just about the most unsuitable conditions for being printed singly in any form, and hence many even clever operators are frequently puzzled how to treat a case of this kind. In such cases, when the original negative is forthcoming, it is always preferable, in my opinion, to deal with it, and not from any print from such, and therefore every exertion ought to be made to obtain the negative with such in any one's possession, no matter how unsuitable the background or surroundings may be, much may be done towards pulling off, either in an enlarged or similar size to the original, a vignetted print from such. To do this, the first step to be taken is a careful block out on the original negative of all the surroundings; and there is one right, and many wrong, ways of doing this blocking out. To many the operation may seem extremely difficult, but in reality, when thoroughly understood, the work is one of much simplicity and ease, provided it be gone about in a businesslike manner. And, first of all, a good retouching desk is necessary; then a good camel's-hair brush, with a long point. (I say camel's-hair, because experience has taught me that, no matter how others may advocate sable, I have always found suitable camel's-hair brushes better than sable for blocking-out purposes), but they must be well selected, and only those that have fine, tapering points used. When such are obtained, they ought to be most carefully guarded from injury, for a good brush is a great acquisition. The next item of importance is a good stock of Indian ink, and here a few words of advice to a novice is necessary. For a modest penny a stick of Indian ink can be purchased from any stationer, and it does seem such a simple matter to those not accustomed to water-colour or blocking-out work, such as we are considering, that with such, and a good brush, all that is necessary is to wet the brush, very likely by placing same in the mouth, and then by rubbing on the Indian ink to obtain sufficient colour as will block out the portions required. Now, I know this is a very common practice, but it is a very slovenly and wrong one to acquire, for it will, before long, ruin the best brush that was ever produced; therefore never attempt filling a brush in such a way. When a cake or stick of Indian ink is acquired, get a common egg-cup and proceed to rub the entire stick down, or melt it in a small quantity of water—say, about as much as will half fill the cup. To do this some little time will have to be taken, and also a fair stock of patience, but this will be amply repaid when the entire stick is melted and the work of blocking out has begun; and, should it, in future time become somewhat dry or too thick, all that is necessary is to apply more water till it is of the proper consistency.

With such prepared, a worker is now ready to proceed to block out the most intricate class of work. To those whose eyesight is all that is desired nothing further is necessary than to lay the

negative on the retouching desk, and proceed carefully to go round the outline of the figure on the film side of the negative (which should have been previously varnished); but, alas! how often does it happen that, before any one sufficiently advanced in photography is called upon to do such work, their eyesight is not what it was, and mostly likely such will require the aid of a magnifying-glass of some kind to enable them to trace closely the finest lines in the work before them. Now, when such is the case, I have no hesitation in recommending a worker to simply employ a pair of strong spectacles in preference to any magnifying-glass. When such are used they permit of both hands being free, and far better and finer work can be accomplished than by the use of a magnifying-glass held in one hand whilst the other wields the brush. To any retouchers, or those who have never tried the comfort of spectacles *versus* magnifying-glasses, I say, not only on grounds of economy, but for solid comfort of working, use strong spectacles, if it is only for a very few minutes when the utmost fine work has to be done, such as touching out very fine spots, or by taking out dark portions with a needle point; then spectacles will be found a friend indeed, and they need not be constantly used.

Having gone carefully round the outline of the face and the figure well over the breast only, proceed to completely block out for some distance the rest of the surroundings with the Indian ink, it is not necessary to fill in the entire negative; this may be done by pasting on paper on the glass side. The parts, most likely, that will give anxiety and trouble are the outline of the face; but this never bothers one who has experience in the work, and all that is necessary is for even a beginner to exercise the smallest amount of care in following, as nearly as he can, the exact outline even in profile work. Should it be found that, from nervousness in a first attempt at blocking out a profiled face, the colour has been allowed to impinge beyond the true line of the face, do not, as one is very liable to be tempted to do, proceed to attempt with the finger, or any other means, to remove the ink; rather let it remain (like weeds sown with good seed) until the whole is finished, then set aside to dry, and, when such is accomplished, get the missus to give you a coarse darning-needle, and with the point of this lightly touch off the colour from the parts the ink encroached upon. Provided the blocking out has been allowed to dry well, there is no risk or trouble in what I may term mere trimming up the work with the aid of a darning-needle, there is danger in using such, although I know many of my pupils at first stand aghast at my suggesting the use of a needle; but they soon get to be quite adepts in its use, and the real difficulty lies in keeping them within reasonable bounds in using it.

When such a figure has been carefully blocked out, take an ordinary piece of albumenised paper and place in contact with the negative in a printing frame, and print to necessary printing depth. We have now a print with a pure white background, and the next step is to vignette the print. This is also a matter of great simplicity when once understood. Of course, it would never do to place the printed image in printing frame without some protection to the face, &c., therefore recourse must be had to some method of shielding the face and figure whilst the white background is being tinted by exposure in a printing frame to daylight.

Now, some workers advocate the use of a cut-out mask, carefully adjusted over the face of the print; but, after a somewhat lengthened practice, I have come to a very decided opinion that a much better method is not to use any mask or cut-out shield, but to subject the print itself to a further blocking-out process, and this is easily done with the Indian ink and brush previously referred to. Take the print into a darkened room and, with the aid of good candle or gaslight, lay it flat down on a suitable support, and, with the aid of the spectacles (if such be necessary), proceed to cover over the entire image with Indian ink.

Taking care not to block out beyond, or to go into, the white background, it is by no means a difficult job, and really resolves itself into a tracing operation, which any schoolboy can and does often practise at school. This done, set aside to dry. Don't be afraid that your operation will hurt the surface of the paper—that won't take any harm. When dry, your picture will have the appearance of a silouhette of olden times. Place same on a printing frame carrying a sheet of glass, and proceed to adjust a vignette cover over the frame; this done, expose to daylight—a few minutes will suffice to tint down the background round the face and figure, and, when dark enough remove from the frame, and proceed to tone and fix the print. The first washing water will, with the aid of the fingers lightly rubbed over the surface of the print, remove the Indian ink, then toning and fixing goes on just as usual. One or two trials will enable any worker to easily accomplish what was considered a most difficult feat in photography. This is one way, and a very reliable method of removing an undesirable background.

There is another very common trouble of a similar kind met with, more especially when printing lantern slides from negatives that are thin, or in cases where the faces are not relieved with light or suitable backgrounds. I refer to such cases where it is desired to print a slide in vignetted form, the negative of which has a dark background. I have known this operation puzzle many workers also, and yet it is very easy when properly gone about.

Take the negative, no matter what size it be, and place it on a retouching desk. Then, with the aid of some oil paint on the glass side, with a brush draw a suitable vignette shape round the head and bust. Crimson lake, or Prussian blue, or any other transparent colour, should be used, and, having drawn a suitable shape, with the pad of the finger proceed to dab down the inner edge of the circle of paint. Set aside to dry, and to assist such it will be found the addition of a little pale drying oil to the colour will tend to facilitate matters in this respect. Next take a colour of a non-transparent nature, such as black, and go round the outer edge of the transparent ring. If the first attempt does not sufficiently blend or soften the inner edges, go over it again with the colour and finger until the negative itself has been virtually turned into a vignetting glass, then go ahead and print with an absolute certainty of success. This is a very useful dodge to follow in many cases, and I have known instances where the outside edges of the negatives ran close into the image where it was the only possible way of vignetting such. T. N. Armstrong.

ON DEVELOPMENT OF "INSTANTANEOUS EXPOSURES."

[London and Provincial Photographic Association.]

When our Secretary unfortunately (for me) asked me to open the discussion to-night on the development of instantaneous exposures, I asked to be excused, as I do not think that I can add any new facts to the already voluminous instructions, formulæ, and treatises on the subject; all that I can do is to state a few of my own experiences and methods of working. I must premise my statement by assuming that what is meant by development of instantaneous exposures I presume to interpret as the obtaining the best results from plates that have had a bare or insufficient exposure, because, although full exposure is often attained and even over-exposure occasionally met with, I take it that the difficulty lies in obtaining the maximum of detail—with other good qualities—with the minimum of exposure. Bearing this in mind, I will now state the different developers that I have used and the advantages and disadvantages that I have found with them.

I started with pyro and ammonia, and quickly found that, if used beyond a certain strength (the ammonia, I mean), chemical fog invariably ensued; the same effect was caused by longer development with a weaker solution, and in both cases iridescent surface markings were produced, while the smell of ammonia is very objectionable to me. Of course, if bromide is used, the fog can be prevented, but only by the sacrifice of shadow detail and good gradation.

When hydroquinone was introduced I hailed it with delight, as I thought that the above defects would be cured; and so they were, but other disadvantages cropped up. With carbonate of soda, the time taken to develop a plate was abnormally long—with potassium carbonate it somewhat shortened, but frilling was much in evidence—but the most serious objection in both cases was that the scale of gradation obtained was bad, the high lights completely blocked up, the half-tones weak, and the fine detail in the shadows worth nothing when printed; in fact, the negatives were very hard. Then the caustic alkalies were tried; and with caustic soda I worked for some time. More detail was obtained, and at the same time the high lights were less like lumps of coal, the gradation better (apparently), and the negatives nicer to look at; but their prettiness was deceptive when you came to print. Although they looked sparkling and strong, the prints were very much the reverse. I also fancied that the grain of the deposit was much coarser, owing, perhaps, to the rapidity of development, which was extraordinary compared with the carbonates in warm weather, but temperature played havoc with the time taken, and also with the results. In the winter half an hour would sometimes pass before the image began to appear, and when development was finished the plate had all the defects common to those done with carbonate.

In hot weather, the deveveloper was quite unmanageable; bromides certainly made it usable; but the resulting negatives were again hard, so this was given up. Caustic potash gave the same characteristics, with the addition of causing frilling "in excelsis."

Eikonogen I tried, but not extensively. I could not get sufficient

vigour, although detail was abundant, and the grain of the deposit very fine indeed.

I now come to a developer that I think fulfils all the requirements that one can desire, that is to say, all the detail in the shadows that is possible, vigorous high lights, without the undue blocking up characteristic of hydroquinone; no chemical fog with even prolonged development, the half-tones well rendered, and the printing capacity all that can be wished, the grain of the deposit is fine, and the colour of the deposit a greenish black, which I, and I think many others, prefer to the bluish and greyish blacks produced by hydroquinone, eikonogen, &c. The developer I refer to is pyro and soda compounded in the following proportions:—

Pyro	480 grains.
Soda sulphite	4 ounces.
Citric acid	30 grains.
Water to	10 ounces.
Anhydrous carbonate soda	480 grains.
Soda sulphite	160 „
Water to	10 ounces.
Take of pyro solution	20 minims.
„ „ soda „	240 „
Water up to	1 ounce.

I have said, Take of soda solution 240 minims, this is the quantity I generally limit myself to per ounce; but I of course do not add it all at once, in five cases out of ten not more than half the quantity will be required. Bromides I never use excepting I fear much over-exposure, I prefer to increase the quantity of pyro.

You will notice that the quantity of soda sulphite added to the carbonate solution is in the proportion of 1 to 3 of the carbonate, this I have found to be the best adjustment of the quantities in order to obtain the colour of the image I have previously mentioned, namely, greenish black. If more is used, a pure black image is the result. If it is absent entirely the negatives are liable to get stained, I lay stress on the use of pure anhydrous carbonate of soda. In my idea it does not stain the gelatine so much, it is a definite compound, is not subject to deterioration, and is stronger. I must ask you, gentlemen, to understand that what I have said only refers to my own individual experience, I have no right to assume that others, having more knowledge and experience than myself, are not equally and more successful with the developers that I have maligned. Other reducing agents I have not tried because I am quite satisfied with the one mentioned, and I very much deprecate constantly changing and experimenting with developers and plates.

E. W. Parfitt.

THE PHOTOGRAPHIC MAP OF THE HEAVENS.*

The first number of the second volume of papers published under the auspices of the Permanent Committee charged with the execution of the photographic map of the sky has made its appearance, says *Nature*, at a sad moment in the history of the undertaking, for, simultaneously with its appearance, is announced the death of him who, more than any other man, has contributed to its success and brought it within the range of practical science. Admiral Mouchez has known how to secure, not only the active co-operation of many astronomers, but also how to make them zealous in the great work, the arrangement of the details of which has occupied the last years of his life. He has awakened enthusiasm for the success of his scheme, and smoothed many difficulties which might have hindered its progress, and probably few undertakings of equal magnitude and equal importance, breaking new ground in many directions, have been got under way with less friction and fewer disappointments. We may well hope that the same suavity and diplomacy which has characterised the conduct of the late Director of the Paris Observatory will be found in the counsels of his successor, and that a work begun in so much hope will be carried to a successful issue.

The papers in the volume before us can be brought roughly under two heads, both, notwithstanding the lapse of time from the inception of the scheme, betokening an initial stage in the preparation. One of the topics under discussion has for its aim the selection of a method which shall secure on the photographic plates, destined ultimately to furnish a catalogue, the impression of stars of the eleventh magnitude with certainty and uniformity; the other, a means of deriving the co-ordinates of the star images so impressed with the greatest facility and sufficient accuracy.

To deal with the second of these proposals first, we may remind our readers that, whatever method of measuring the positions of stars on a plate may be adopted, the resulting co-ordinates must be purely differential, and probably referred to the axes of the *réseau* impressed upon the plate as a latent image, and developed under the same conditions as the stars themselves. To pass to the determination of R.A. and declination, a great deal of information, entirely independent of photography, will have to be made available. The readiest means of effecting this last step in the reduction, as it appeared to a committee of experts appointed to consider the question, was to determine, by meridian instruments, the actual co-ordinates of six stars on each plate. It is needless to comment upon the magnitude of the labour thus undertaken, or, at least, contemplated. This preliminary work would demand a catalogue of some sixty or seventy thousand stars, most of them below the ninth magnitude, and not found in existing catalogues. In order to give to each determination the necessary accuracy, it is desirable that each star should be observed twice in both elements, and at two observatories. When we remember the length of time that the re-observation of Argelander's zones has consumed, and is still incomplete, we can form some estimate of the time that must inevitably elapse before the results of the photographic catalogue can be made available for astronomical purposes.

In presence of these difficulties, and many more which occur to the practical astronomer, we must be very grateful to M. Loewy for elaborating a scheme which, if it be found practicable, will materially shorten the time necessary for the production of the catalogue. M. Loewy proposes to avail himself of the fact that the plates are taken in two series, in such a manner that each corner of a plate in one series will form the centre of four other plates in the second series. When, therefore, the astronomer has determined the rectilinear co-ordinates of the stars on *one* plate relative to the central lines of the *réseau*, each of these stars will belong in common to the plate considered, and to one of the four plates in the second series, partially covering the first. M. Loewy's scheme consists in making the stars on the four plates thus connected available for the reduction of the first. And, on paper at least, it is not difficult to extend the scheme still further, and to make the plates contiguous to these four contribute to the reduction of the original plate by means of an extended triangulation. In this way a plate would not be considered as an isolated fact, but a considerable area, of 36, 64, 100, or more square degrees could be woven into an harmonious scheme of reduction. And such a plan possesses this very obvious advantage, that on even a lesser area, as of 36 square degrees, we may well expect to meet a sufficient number of bright stars whose places are already so well determined that the reduction of the plates could go on immediately without waiting for the observations of the stars on the meridian. And, independently of this evident advantage, it seems highly probable that two of the elements of reduction—viz., the orientation of the plate and the value of the scale—will be determined more accurately if the stars which are used for the derivation of these corrections are separated by a considerable distance—that is, greater than a single negative would permit.

M. Loewy considers the various sources of errors and their necessary correction with all the detail required to submit the plan to practical application, and this is precisely the test that is needed. This appears to be also the opinion of Dr. Gill, expressed in a very cautious approval of M. Loewy's scheme, and he further quotes a remark of Professor Anwers, which contains a very salutary caution. That astronomer points out that the reduction of the catalogue plates will be most accurately effected from to position of *faint* stars, rather than from bright ones. In that case, since our present most accurate catalogues do not give the position of the fainter stars, those catalogues will still need to be supplemented by many meridian observations. Dr. Sande Bakhuyzen, however, expresses the opinion that the zones of the *Astronomische Gesellschaft* will, when completed, furnish the necessary data for all reductions, or, at most, require additional observations in some portions of the sky, which he is able to point out from a careful examination of the number of the stars contained in these zones.

The second topic which has received much consideration in this volume is, as before mentioned, the adoption of a method to secure the registration of stars of the eleventh magnitude. It will be remembered that the International Congress of 1891 proposed to place in front of the object-glass of the telescope screens of fine metallic gauze, identical in manufacture, and of such construction that the amount of light impeded should be equivalent to two magnitudes, the coefficient 2·512 being employed as the ratio to express the relative brilliancy between two consecutive magnitudes. A Committee was appointed to carry this plan into execution, but the report which this Committee has issued is unfavourable to the adoption of the method. The signatures of the Astronomer Royal, Professor Pritchard, and the brothers Henry are attached to this report; but M. Vogel, the remaining member of the Committee, has not found the reasons assigned by his colleagues sufficient to warrant the rejection of the scheme, and consequently his name does not appear. The Presiden

* *Bulletin du Comité International Permanent*, tome ii., premier fascicule.

of the Permanent Committee thus sums up the case against the proposal. Light, in traversing a metallic screen of bright threads and very narrow mesh, seems to experience, besides the ordinary effects of diffraction, certain modifications, whose cause is not yet explained, and which the Congress could not foresee when they framed the recommendation. This peculiar behaviour of the light demands further study, and renders the application of this means very difficult, if not useless, for the purpose for which it was proposed, since the discrepancies of the results obtained are greater than the error which an experienced astronomer would make in estimating stars of the eleventh magnitude.

The experiments on which this conclusion is founded are set out in considerable detail, and a careful study of these experiments ought to convince an unprejudiced critic that the Committee was justified in advising the rejection of the screens as an adequate and efficient means of deciding upon stars of the eleventh magnitude. It should be stated that the gauze screens, identical in character, were furnished by Professor Vogel, and, though there is no mention of the experiments or processes which induced the Potsdam astronomers to select a screen of this particular obstructive power, it is to be presumed that in his photographic telescope they stopped the amount of light proposed by the Congress. It is not the least curious feature in the discussion (controversy would be far too strong a word to describe the courteous paragraphs in which the various astronomers set forth their reasons for dissent from the able physicist) that Professor Vogel takes no part in it nor vouchsafes any information as to the principles by which he was guided in the selection, but leaves the onus of rejection entirely to his colleagues, who are thus placed at a disadvantage.

Professor Pritchard, whose photometric researches permit him to speak with authority, has stated concisely the result of his experience. He found that on the ordinary astronomical telescope, achromatised presumably for D, the amount of light obstructed was equivalent to 2·4 mag., and on the photographic telescope, with a minimum focal length for G, the amount of light lost was not less than 2·8 mag. The Astronomer Royal reports that the action of the screen on the Greenwich telescope is to stop 2·5 mag. This result was deduced by comparing the seventh and ninth magnitude stars of Argelander. Some further comparisons of the obstructed and unobstructed light of stars of the ninth and eleventh magnitude, photometrically examined by Professor Pritchard with the wedge photometer, confirmed this result, and further proved that the scale of Pritchard and Argelander was in very satisfactory and close agreement. It will be necessary to return to this point. M. Henry, at Paris, offers results in close accordance with those of the two English astronomers just quoted. He finds that the screen proposed by M. Vogel as effective in his instrument stops between 2·5 and 2·7 mag. on the Paris telescope, and this effect is still further confirmed by some observations by M. Trépied, while M. Rayet, at Bordeaux, finds 2·7 mag. represents the effective action of the screen. Very different is the experience of M. Donner, of Helsingfors. His method of estimating the loss of light is different from that employed in the other cases, and is perhaps not without objection; but the result which he derives from his observations is that the light of a star, in passing through the screen, loses only 1·6 mag.

It is now necessary to describe very briefly the methods employed in the various observatories which have led to these discordant results, the more so as one eminent authority, Dr. Dunér, of Lund, who apparently holds a brief for Professor Vogel, has taken exception to the results deduced. Leaving on one side the experiments conducted by MM. Henry and Trépied on artificial stars, and against which Dr. Dunér urges no objection further than that they are founded on artificial stars, we find that one principle pervades the examination conducted at Greenwich, Paris, Bordeaux, and Algiers. The several astronomers have determined what length of time is necessary to produce a blackened star disc of the same diameter from the same star with and without the screen. In this way it has been found necessary to expose for ten or eleven times as long with the screen before the object-glass as without, and from this fact it has been inferred that the loss of light occasioned by the screen amounts to 2·5 or 2·6 mag. It is urged that, if only two magnitudes were lost by obstruction, the necessary exposure would have been $(2{\cdot}512)^2 = 6{\cdot}3$, that required by the unobstructed object-glass. Dr. Dunér remarks on this that those who have condemned the employment of the screens on these grounds have argued in a vicious circle, and to be logically correct it would be necessary to show that the intensity varies as the time of exposure or—

$$it = \text{const.}$$

Against the accuracy of this law Dr. Dunér urges that reports of the observers themselves show three distinct proofs. In the first place (1(Dr. Donner states that only 0·58 mag. is gained by successively multiplying the length of exposure by 2·5; (2) that the Astronomer Royal proves that a gain of 1·7 or 1·85 mag. is secured by multiplying the length of exposure by 6·25; and (3) that MM. Henry have found that to obtain similar discs from stars of the 9·3 and 11·3 mag. the exposure has to be increased from 28 sec. to 240 sec. (1 : 8·6). These three experiments give instead of 2·512 respectively,

3·28, 2·69, 2·93,

results apparently incompatible with the formula—

$$it = \text{const.}$$

MM. Trépied and Henry reply at length and effectively to these strictures. They do not regard 2·69 and 2·93 as differing so greatly from 2·512 but that the discrepancy may be fully explained by inaccuracy and paucity of observations. The Helsingfors result (3·28) they refuse to accept as unequivocal evidence in the face of established facts. The method of Dr. Donner consisted in comparing photographs of the Pleiades, taken with and without the screen, with the map of M. Wolf, and marking the number and magnitude of the stars which have black or grey images. This method, as already hinted, does not seem to be entirely free from objection. Admitting that the comparison of the images was made, as we are sure it was, with all the care possible, there is still room for the varying exercise of individual judgment as to what constitutes a black and what a grey image, and the final result is likely to be less exact than a process based upon rigorous measurement.

The method employed by Professor Pritchard is, perhaps, as free as any from objection or misinterpretation. He exposed the plate for *equal times* with and without the screen, and then measured the diameters of the resulting star discs. If two discs, produced one with, and one without, the screen were found equal in diameter, then the effect of the screen is equivalent in photographic action to the original difference of magnitude between the two stars. This difference of magnitude was determined by the wedge photometer, and the only exception that can be taken to this determination is that the scale of the wedge photometer may not be accurately applicable. But here we have the distinct assertion of the Astronomer Royal, reiterated again by M. Trépied, that the Pritchard Argelander scales are in very satisfactory accord. This circumstance is the more gratifying for two reasons. First, because it is distinctly stipulated in resolution 19 (1889), "Chaque observateur devra s'attacher à obtenir sur ses clichés destinés au catalogue la grandeur 11·0 déterminée aussi exactement que possible *au moyen de l'échelle d'Argelander*." The maintenance, therefore, of the scale of Argelander becomes of paramount importance, and this one could scarcely hope to effect by means of the gauze screens. The second satisfactory point is, that Professor Pritchard is endeavouring to secure uniformity in the photographed stars by distributing among the participating observatories small charts of particular regions of the sky on which are marked stars of the ninth and eleventh magnitudes approximately. Naturally, in the determination of the magnitudes of the stars on these charts, the scale of Argelander will be perpetuated; and, inasmuch as the testimony of several astronomers is distinctly in favour of making use of these typical areas, it seems very probable that Argelander magnitudes will be prolonged in the catalogue work down to the faintest stars impressed.

HARMONISING HARSH NEGATIVES.

[North Middlesex Photographic Society.]

THE subject of my paper is one for which, if dealt with by a competent person, probably no apology would be necessary. I am fully impressed with a sense of my unfitness for the task, and the only excuse I can offer for touching it is that when, in the course of my duty, I have requested some of our members to take up the corner of one of the large subjects as the theme for a paper or demonstration, I have been met with the rejoinder, "Why not try it yourself?" I am consequently in the unenviable position of a man who attempts to put his own precepts into practice.

Probably the most scathing and unanswerable criticism upon pictorial photography is that our prints are too black and white, too violent in contrast, that when viewed at arm's length they appear to be masses of black and white without relief in the shadow or gradation in what should be the lighter half-tone, or, if both are to some extent secured, the general effect is poor and flat. This criticism, though not applicable to the pictures produced by our better workers, is, unfortunately, too true when applied to the prints made by the majority of our rank and file, among whom I may claim to have a place.

The cause is not far to seek. A moment's reflection will serve to show that no process can reproduce nature's black—the total absence

of light as in the case where our darkest shadow is some spot where light cannot penetrate; nor can it reproduce nature's highest light—light itself, or light reflected from water or other bright surface. Our deepest black and whitest paper fall far short of these extremes; and, even if it were possible to secure in a negative the full scale of light and shade as seen in nature, it is certain that no printing process on paper can give the gradation found in a strong negative.

If we expose a plate rich in silver, and preferably isochromatic, on some well-lit subject, showing deep shadow in the foreground, and having strongly defined clouds in the sky, and develop in the ordinary manner, we will have a negative in which the shadows are nearly clear glass, and the cloud-forms, though extremely dense, will yet be clearly perceptible. On making a print, we will find that, long before the faint shadow markings in the clouds are impressed upon the paper, possibly even before the distant portions of the landscape are visible, the darker half-tone will be one mass of black. Our printing process is only capable of rendering one end of the long scale of light and shade in the negative. Some compromise must be attempted. Artists have their own methods of overcoming the difficulty, and vary them to suit their subjects. In some cases they may use up the longer portion of the scale at their command in translating the lighter half-tone and compress the shadows into the remaining portion. In another case they may employ the opposite method, the shadows and darker half-tone may be fully rendered, and the lights compressed. In a third case the whole scale may be uniformly compressed within the limits of the medium of expression; but the favourite method appears to be to introduce two or more scales into the composition, with the result that, while the lighter half-tone may be much darker than in nature, yet, the local contrasts being preserved, the painting or drawing conveys to the eye much the same impression it would receive from the scene in nature.

It is for us to consider to what extent we can make use of these methods in photography.

When we mask the landscape portion of a negative to allow the clouds to print out, or when we combine in the prints clouds from another negative, we are introducing two scales of light and shade into our composition. Masking and double printing, or sunning down parts of the print, are the readiest methods of obtaining harmony in what would otherwise be harsh prints. But, when the lights and shades are intimately mingled, masking is difficult, and sometimes practically impossible, and the results of running down are sometimes far from pleasing.

If now we attempt in making the negative to compress the full scale of lights and shadows within the limits of our printing process (and this is quite possible by the method recommended by Captain Abney, *i.e.*, by developing first with full quantity of ammonia, and just a trace of pyro and continuing the development of the ghost image so obtained with full quantity of pyro and little ammonia), we are met with another difficulty, that of flatness, and here I would like to quote from an article in the *Photographic Quarterly* for April in this year, entitled "Nature's Light Scales as Rendered by Photography," by Mr. H. Dennis Taylor. Mr. Taylor says (pages 180, 181, 182):—

"——the eye's appreciation of rather high contrasts and great variations in them is clumsy and indiscriminating; extreme contrasts of 1 to 10, or, better still, 1 to 20 in a photographic print yielding to the eye much the same sort of impression as extreme contrasts of 1 to 50 or more in nature, would yield, especially when the print is not directly compared to the original scene. But it was also shown that, although to the eye one high contrast is much the same at another high contrast, nevertheless the eye is extremely sensitive relatively to variations in those moderate contrasts which exist between contiguous features and details of natural views, and which give them their distinctness and relief.

"Hence it follows that, while such extreme contrasts as 1 to 15 or 20, which are available in a photographic print, will do very good service for giving an idea of very much higher contrasts existing in nature, still those moderate and delicate contrasts existing between the essential details of the natural view cannot be lowered in value (by that compression of the light scale which is necessary and unavoidable in the print) without the eye being at once struck by the divergence from reality, and being disappointed by a flatness and want of vigour which does not do justice to the original."

And again:

"As a still more telling illustration or proof of the above statement, let a long series of small rectangular spaces be imagined in immediate contact, each being exactly $1\frac{1}{99}$ (or 2 per cent.) brighter than its neighbour on the left. If there are 325 of these strips, the photometric contrast between the darkest on the extreme left and the brightest on the extreme right will be as 1 to 100. Now, a difference of two per cent. in brightness between two strips in immediate contact is easily perceptible to ordinary eyes; therefore all the strips would be clearly distinguishable from another, and would constitute the *details* of the series. Now let a photograph of the series be produced in such a manner that the contrasts between the two extreme strips is reduced from 1 to 100 down to 1 to 5 (a trifle over). The light scale is thus very strongly compressed, and it then follows that the contrast between any two contiguous strips will now be as 1 to $\frac{1}{99}$ or a difference of $\frac{1}{2}$ per cent. instead of 2 per cent. as before. Now it has been proved by careful experiments with the experimental top that such a small contrast as this is absolutely imperceptible to ordinary eyes. Therefore it follows that the rectangular strips will *no longer be discernible*, and that the whole effect would be that of a gradual and unbroken shading from one extreme of the series to the other. In other words, the details of the original have been altogether obliterated by the compression of the light scale, although a passable degree of contrast between the extremes is still preserved. The pith of the matter may be summed up thus:

"While photography enables one to compress a very extensive natural light scale into the much narrower limits at the command of the printer, still it performs the operation in a strictly mechanical and accurate way by modifying all contrasts, great and small, according to photometric laws, whereas human vision does *not* estimate or appreciate natural and artificial contrasts in a manner directly related to their photometric values, but is far more sensitive to modifications in the smaller contrasts than it is to modifications in the greater contrasts."

It follows that only in a few exceptional cases the compression of the whole scale within the limits of our process will yield satisfactory results. A practical difficulty will also be found in gauging in the dark room, during the process of development, the exact amount of compression necessary. The introduction of two scales into the composition, or the compression of one end of the scale, will be found more generally useful and pleasing. Reduction or intensification will effect the latter result.

The intensification of a flat negative showing too compressed a scale will show a result somewhat as if a darkish print had been made from the negative in its original state, and the lights put in with white crayon; or, when the negative happens to be dense as well as flat, relief may be obtained by clearing out the shadows with a reducing agent. If this be crisply done, the result will be as if a light print had been taken from the negative in its original state, and the shadows strengthened with black crayon. If these methods be applied locally, two scales are shown in the print; if applied generally, the effect is that of compressing one end of the scale and rendering the other more fully. For some classes of subjects these methods will yield pleasing results.

In the case of harsh negatives, where the shadow detail is already too thin, and the lights too dense, neither of these methods is quite satisfactory. In attempting to reduce the high lights which penetrate through the film to the support, it will only be by the exercise of an amount of manual dexterity not usually possessed by an amateur, and then, at the expense of a vast amount of time and patience that, we can avoid clearing away the shadow detail lying on the surface of the film when the light and shadow are intimately mingled.

When the lights and shadows are in masses, and soften into each other, the lights may be satisfactorily reduced by means of Mr. Howard Farmer's reducer (hypo and ferricyanide of potassium), applied by a sponge. A member of our Society (Mr. Beadle) is very skilful in the use of this agent, and has kindly lent me some prints from negatives, before and after reduction, which I pass round for inspection. In the prints of the chapel interior you will note the great improvement in the columns, font, and the wall, upon which the light falls so strongly. In the landscape you will note how charmingly the distance prints out from the reduced negative.

The difficulty in using this method is to avoid reducing the shadow detail adjacent to the lights, and to avoid a patchy appearance, due to unequal reduction. The same remark will apply still more strongly to the use of spirit applied with wash-leather, as some pressure has to be applied, and, if the portions to be reduced are at all large, the difficulties become very great. I have never seen an instance of a large portion of a negative reduced with spirit without patchiness appearing, generally accompanied by a smeary effect.

It is not necessary for me to give here formulæ for the many intensifiers and reducers extant, each of which has its own advantages for special purposes. A full list of these, with useful comments and explanations, will be found in the admirable paper read before our Society last year by Mr. Roland Whiting. I may, however, call your attention to one which has been referred to lately at some of the Societies. The formula as given by Mr. Teape at the London and Provincial is

Bichromate of potassium saturated solution	1 drachm.
Sulphuric acid	1 „
Water	8 ounces.

This is a stock solution to be diluted for use according to the purpose for which it is required. For instance, if it is only necessary to clear away a slight surface fog before intensification, it should be diluted to

a pale lemon tint. When dense negatives have to be reduced, a stronger solution may be used. I have found it speedy, and, when applied to the whole surface of the negative in a bath, regular in its action. The effect is visible during the operation, and as hypo, is not used, a lesser amount of washing is necessary than when that useful but troublesome chemical is employed. J. McIntosh.

(To be continued.)

THE PHOTOGRAPHIC SOCIETY'S STANDARDS.

[The following is reprinted from the Society's Journal.]

The Standards adopted by the Society in 1881 have been carefully reconsidered to see what additions or modifications were desirable.

The following statement is complete so far as the subjects it deals with are concerned:—

Lens Diaphragms.

It is recommended:—

1st. That the aperture of the standard-unit diaphragm have a diameter equal to one-fourth the equivalent focal length of the lens.

2nd. That diaphragms with smaller openings have apertures diminishing in area to the extent of one-half from the unit standard downwards.

3rd. That every diaphragm be marked with its intensity ratio, and also with the relation that the diameter of its aperture bears to the equivalent focal length of the lens, thus:—

$$1\frac{f}{4};\ 2\frac{f}{5{\cdot}6};\ 4\frac{f}{8};\ 8\frac{f}{11{\cdot}3};\ 16\frac{f}{16};\ 32\frac{f}{22{\cdot}6};\ 64\frac{f}{32};\ 128\frac{f}{45{\cdot}2};$$

$$256\frac{f}{64};\ \&c.$$

Should a lens not admit of a diaphragm with an aperture as large in diameter as one-fourth its focal length, nor exactly any one of the above-mentioned sizes, it is still recommended that all the apertures be made in uniformity with the above scale, with the exception of the largest, which should be marked with the number its area requires in relation to the unit diaphragm. In the case of a lens having a working aperture exceeding in diameter one-fourth its focal length, the diaphragms should be marked according to the sizes of their relative apertures, for example:—

$$0{\cdot}5\frac{f}{2{\cdot}8};\ 0{\cdot}25\frac{f}{2},\ \&c.$$

And diaphragms which require to be made with apertures intermediate to the standard sizes should be marked in a corresponding manner.

Lens Mounts and Fittings.

It is recommended:—

1st. That the equivalent focal length of each lens be engraved upon its mount.

2nd. That the following series of screws for photographic lens flange fittings be adopted:—

Diameter in Inches.	No. of Threads per Inch.	Core Diameter in Inches.
1	24	·9466
1·25	24	1·1966
1·5	24	1·4466
1·75	24	1·6966
2	24	1·9466
2·25	24	2·1966
2·5	24	2·4466
3	24	2·9466
3·5	12	3·3933
4	12	3·8933
5	12	4·8933
And upwards, advancing by inches.	12	

The form of thread is that known as Whitworth's Angular Thread, and is designed as follows:—Two parallel lines, at a distance apart equal to 0·96 of the screw pitch, are intersected by lines inclined to each other at 55°. One-sixth of the vertical height of the triangular spaces so obtained is rounded off both at the top and bottom. The depth of this thread is 0·64 of the screw pitch.

3rd. That every flange and adapter have a mark upon its front to indicate the position of the diaphragm slot or index of any lens when screwed home. The mark on any adapter should coincide with the mark upon any flange into which it is screwed. This mark should be placed at the point at which the thread becomes complete at the shoulder of the flange or adapter.

Camera Screws.

It is recommended:—

That all screws fitted to cameras, either for attachment to the stand, for fixing rising fronts, or for other movable parts, be either $\frac{3}{16}$, $\frac{1}{4}$, $\frac{5}{16}$, or $\frac{3}{8}$ of an inch in external diameter, and in pitch of thread and other details in accordance with the generally recognised Whitworth standards for these sizes.

Our Editorial Table.

Convention Prints.

Two bromide prints received from Messrs. Morgan & Kidd, Richmond, attest at once the skill of Mr. R. L. Kidd, of the firm mentioned, as the user of the camera, and of his firm as enlargers and printers in bromide. One is a whole-plate direct group of a party of friends who, in the West Highlands, kept up the sociable character of the Convention for several days after the scientific proceedings had terminated in Edinburgh. As a memento of the happy time, containing, as it does, the portraits of more than a score of friends taken *al fresco*, it will be esteemed quite as much as for its technical excellence. The other is an enlargment ($22\frac{1}{2}\times16$) from a small negative of the Convention group taken by Mr. Kidd, the tone and brilliance of which speak much for the skill displayed in the process of enlarging.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
August 22	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 22	Gloucestershire	
,, 22	North Middlesex	Jubilee Hall, Hornsey-road.
,, 23	Great Britain (Technical)	50, Great Russell-st., Bloomsbury.
,, 24	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 25	Birmingham	Lecture Room, Midland Institute.
,, 25	Hackney	Morley Hall, Triangle, Hackney.
,, 25	Halifax Photo. Club	Mechanics' Hall, Halifax.
,, 25	Hull	Royal Institution, Hull.

,, 26	West London	Chiswick School of Art, Chiswick.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

August 11, Mr. T. E. Freshwater in the chair.

Packets of Ilford printing-out paper were distributed amongst the members.

Mr. W. D. Welford showed results of his hand-camera work during the Convention at Edinburgh; he also gave the formula for a successful bath for the Eastman chloride paper, which he had arrived at after many experiments, viz.,

Gold	4 grains.
Water	6 ounces.
Bicarbonate of soda	1½ drachms.

This would tone 108 quarter-plates, after toning was slightly, and fix in bath strength 1 to 6. Toning was very rapid.

Mr. Everitt had found the same paper tone well with a borax bath.

Mr. Dando used an old acetate bath which took a long time to tone, but any tone could be got by it.

Mr. Birt Acres made a personal statement, condemning the report of a former meeting which appeared in one of the photographic journals. Some discussion ensued, and it was generally agreed that, as to a certain portion of it, the report was inaccurate. It was decided to withdraw that portion. Mr. Birt Acres expressed himself as being satisfied.

Mr. F. A. Bridge showed a splendid enlargement, 30×20, from a quarter-plate negative of Melrose Abbey, taken during the recent Convention meeting. He presented it to the Association, and was warmly thanked.

Mr. E. W. Parfitt then opened the discussion of the evening by reading a paper on the *Development of Instantaneous Exposures.* (See page 536).

In the discussion which followed, Mr. Birt Acres stated that pyro and

ammonia used very weak, without bromide, would bring out as much as any known developer. He would use one-eighth of a grain of pyro, and an equal quantity of ammonia, to the ounce.

Mr. W. E. Debenham would use the same strength of pyro, a little more ammonia, and he found that by using a small quantity of bromide detail was not held back, but kept clearer.

Mr. WELFORD alluded to the necessity of trying everything in this age of progress, both in developers and plates. He had tried everything, and came back to pyro. Rodinal was good, but no density seemed to be obtainable, but by the after-application of hydroquinone great vigour resulted, but too much intensification. He preferred soaking the plate first in soda, then adding pyro, and recommended the Ilford formula with more soda added to start with.

Mr. Guardin used ten per cent. solutions of pyro and soda, beginning weak, and adding as required.

Mr. Sinclair would begin with a small quantity of pyro, adding by degrees, to obtain density, very little bromide.

Mr. BERT ACRES did not approve of soaking the plate first in alkali; he said more plates were spoilt in forcing than in any other way. He advised starting with weak solutions, and finishing up with stronger solutions.

Mr. Teape had been using a plate lately with which a beautiful mauve-coloured fog became evident if he used the smallest quantity of bromide.

The CHAIRMAN, in closing the discussion, said the preponderance of opinion seemed to be on the side of pyro and soda, and, on behalf of the members, thanked those gentlemen who had related their experience.

Mr. E. Bella showed a new developing dish, called the "Developan." The invention claimed that the plate, after development and rinsing with water in the same dish, could be removed from the dish in an ordinary room without danger of fog.

On discussion it was considered that the principle was not new, and that it was not safe to remove the plate from the dish in daylight even after rinsing.

Mr. BERT ACRES, alluding to the non-actinic glasses used in constructing the "Developan," remarked that orange glass was safer than a great deal of the ruby glass that was used now.

Hackney Photographic Society.—August 9, Mr. Arthur Barker in the chair.—The Hon. Secretary distributed samples of the Paget plates and Ilford P. O. paper. A discussion ensued on the latter. Mr. HENSLER said he noticed a difference in the colour, which was sometimes red and sometimes violet. He preferred the latter. Mr. Nunn differed. Mr. BECKETT said some negatives were more suitable for one colour than another. Blue paper lost the most in bath. Mr. Dean handed round a forced plate. Mr. DANDO said it was very much forced. Mr. Hudson showed some cheap sheaths made by Chipper. Mr. Nunn showed some examples of work on the Paget Phœnix plates which he had been very successful with. Mr. REYNOLDS also reported favourably of the rapid plates. Mr. POULSON asked the Chairman's opinion of the Eastman gelatino-chloride paper. The CHAIRMAN said he had used a quantity, and was much pleased with the results. Mr. W. T. Roberts, of Leytonstone, then showed his hand camera, which could be used on a stand and focussed as an ordinary camera, although being of a magazine kind. Changing could be done in daylight by carrying extra small magazine. Mr. DANDO then read a paper on *Stereoscopic Photography*. He attributed the discovery to Sir Charles Wheatley. A half-plate camera had been used by Mr. Dando for his work, and he said he had found it an advantage, as extra height was allowed. Two different pictures could be taken if desired. Another advantage in the size mentioned was that half-plates could always be obtained. He preferred the shutter just before the plate, and lenses of from five to seven-inch foci. One of the great difficulties was to get them accurately paired. He did not like the Iris diaphragm; sometimes apertures were not equal. Give plenty of exposure, and develop rather thinly, and get plenty of detail. Mr. HENSLER asked how to tell when accurately paired. Mr. DANDO said: Take lens out, pass thin piece of wood through one of the stops so that the wood is marked all round, then repeat on the other. Further discussion was postponed until next meeting.

Burnley Photographic Society.—At a meeting of the Council of this Society, held on the 10th inst., when Mr. John Butterworth, J.P., presided, an animated discussion took place in respect to the proposal to hold an annual exhibition, and a Committee was appointed to investigate the matter and report at a future meeting. Mr. Sutcliffe (the Hon. Secretary) promised to give a number of photographic annuals to the library, and a number of improvements were suggested to the Society's rooms.

Derby Photographic Society.—The fifth outdoor meeting of the season was held on Saturday last at Weston-on-Trent, a large number of members being present, and the weather being all that could be desired, a large number of plates were exposed. Mr. W. L. Mugliston was elected a member. It was decided to hold the sixth outdoor meeting at Repton on Saturday, August 27.

Richmond Camera Club.—August 12, the President in the chair.—The Hon. SECRETARY, after distributing sample packets of plates sent by the Ilford Company, and printing-out paper sent by the Britannia Company, then said that he had some difficulty in stripping gelatino-chloride prints that had been squeegeed on glass. Would xylonite slabs answer better? Mr. Cembrano (the President) had never had a failure in squeegeeing when using the Ilford paper; he recommended for this paper a combined toning and fixing bath. The xylonite slabs mentioned would be a capital substitute for the focussing screen, provided they were made sufficiently rigid and transparent. Mr. DAVIS recommended rubbing it with powdered pumice-stone to get rid of the small bright specks on matt-surface prints. In opening the discussion on *Developing Under-exposure*, Mr. DAVIS said he employed the old method of first soaking the plate in a weak solution of the accelerator, pouring this off and applying the usual developer. This system answered well when the plate was known to be under-exposed, but there was danger of spoiling the negative if the exposure happened to be a full one. Mr. Ennis preferred diluting the developer with four times its bulk of water; then, when the image was well out, he would use a fresh developer containing little bromide. Mr. Hunter would begin with a developer containing less pyro, ammonia, and bromide, and when all the possible detail was out he would strengthen it by adding plenty of pyro and more ammonia. Mr. Cembrano thought that, if the plate was really under-timed, no good could be done with it. It was in under-exposure that defects in the manufacture of the plate would become very apparent. He believed that in practice there was no real advantage of any one developing agent over another. When having a good subject, the best and safest plan would be to expose two or more plates on it. Mr. Ford had not succeeded in real cases of under-exposure, not even after developing for two hours. To gauge correctly the exposure for subjects under trees was a difficult matter. Mr. Ennis found the soda developer recommended by the President to wash well for hand-camera exposures. It was made as follows: Sulpho-pyrogallol (ten per cent.), 20 minims; Washing soda (ten per cent.), 240 minims; Bromide of potassium (ten per cent.), 2 minims. Made up with sulphite of soda (ten per cent.) to one ounce instead of plain water. Mr. Davis found it was essential to use bromide with the pyro-potash soda developer. Mr. ENNIS asked for the best way of mounting glazed gelatino-chloride prints. Mr. DAVIS said Houghton's Excelsior mountant was good. Mr. FORD added that indiarubber solution answered, but it caused the prints to fade. Mr. Ennis had had a similar experience with this mountant when mounting prints on albumenised paper.

Sheffield Photographic Society.—August 9, Mr. B. J. Taylor in the chair. Arrangements were made for an excursion to Whitby. The Secretary distributed sample packets of the Paget prize plates for members to report thereon at the next meeting. Several members also gave in their report in reference to Eastman's printing-out paper, which was considered highly satisfactory. It was also arranged to send the annual competition pictures to London for judgment.

Spen Valley Photographic Society.—August 9, Dr. Farrow, President, in the chair.—The adjudication in the monthly competition, the subject of which was *Caught*, was proceeded with, the prize being awarded to Mr. J. Burnhill for a live rat in a cage trap. This was also the time appointed to judge prints sent in to the Sutherland competition, and as it was the first competition of the kind, and in which any prize of value had been competed for, there was considerable interest taken in it. The subject was Lower Bacup Farm from a given aspect. There were ten exhibits, all of which were very creditable to the competitors, the prize being awarded to Mr. H. Jackson. A discussion then took place as to the best means of judging photographs at future exhibitions of the Society.

PATENTS COMPLETED.

IMPROVEMENTS IN AND RELATING TO CAMERA TRIPODS.

No. 10,869. LEONARD E. BENNETT, City of McHenry, County of McHenry, State of Illinois, United States of America.—*July 9, 1892.*

[THIS invention has relation to photographic cameras, and more particularly to that class thereof wherein a tripod is employed for supporting the camera, said tripod being adapted to be connected with, and disconnected from, the camera, and the primary object of the invention is to provide simple means whereby a tripod may be readily connected with, and disconnected from, the camera, said securing means being provided with locking devices, whereby the parts may be locked in position after having been connected together.]

IMPROVEMENTS IN HOLDERS FOR OBJECT GLASSES AND LENS TUBES.

No. 10,971. JAMES SWIFT, 81, Tottenham Court-road, London.—*July 16, 1892.*

THE object of this invention is to provide simple and efficient means for securing object glasses and lens tubes to microscopes, cameras, or other scientific instruments, and the invention consists in forming the lens socket with a fine thread round one half of its interior surface, and adapting to the other portion a threaded block, which is thrust forward to grip the lens tube by means of a cam action.

(In accompanying drawings several modes of carrying out this invention are shown and described.)

Improvements in Magic Lantern Slides.

No. 13,765. George Frederick Luttickе, 23, Farquhar-road, Norwood, S.E. *July* 16, 1892.

I provide a frame of anitable shape, construction, and material, having one or more grooves, holes, slots, or the like, serving as guides for suitable slides.

My invention, firstly, refers to novel means for operating in such manner as not to be perceptible on the screen-jointed figures, or objects of suitable material, or part or parts of same, such figures or objects being conveniently mounted or arranged on glass slides or suitable projections from some part or parts of the frame.

The novel means I employ for the said purpose are pins or the like conveniently fixed to the part or parts, or to cranks in connexion with part or parts which it is intended to move, such pins or the like passing through holes or alots in or being connected with a glass slide or disc in an equivalent manner, auch glass slide or disc being capable of movement in any desired direction or directions, and being preferably of such size and shape as not to show any edges when operated.

In the case of circular motion, the operating slide or disc either has a slot, small enough to be covered by the figure or object, or part of the figure or object, to be moved, or sufficient play is allowed in the depths of the grooves or aize of slots in which the opening slide or disc travels. Or both slides may be made capable of motion.

I may reverse the arrangement by suitably fixing pins or the like to a glass alide, and pass same through holes, slots, or the like, in the said figures or objects, providing, where necessary, caps, or the like, to prevent light showing through.

I may use three slides, tha centre one being stationary, and the two outside slides moving one or more figures or objects in the manner described either directly or indirectly by means of cranks or the like, working spindles or the like.

It may be useful to provide the pins or the like, which serve to operate the figures or objects, or parts thereof, with one or two plates or rings, one on each side of the operating slide or disc, so as to prevent the pin from shifting, thus obviating irregular motion in the figures or objects, or parts thereof.

I reserve to myself to arrange the said figures or objects in any other suitable way without departing from the gist of my invention.

I may also use suitable stops, rollers (to admit of easy sliding), springs, or weights in connexion with the glass slides or discs, and the operating of the same.

Secondly, in order to carry motion from one limb or part of a jointed figure or object to another, I may employ a lever conveniently pivoted to the said figure or object, and operating by means of slots, pins, or the like, conveniently fixed to the limbs or parts, or *vice versâ*.

I may also provide a plate, or plates, or the like, suitably mounted to a slide or projection from the frame in a stationary position, provided with a pin or pins, or the like, acting by means of levers, rods, or the like, on a part or parts of a figure or object revolving on a common spindle.

Thirdly, I claim the following means for producing novel illusory effects, viz., I provide a plate, table, cupboard, or the like, pivoted or otherwise conveniently fixed to a glass slide or part of the frame, such plate, or the like, coucealing a roller, or the like, in bearings worked by a suitable spring in one direction.

To such roller, or the like, I attach one end of a figure, animal, or any object made of suitable flexible material, so as to be capable of being wound round the said roller, or the like.

The free end of such figure, animal, or object is conveniently attached to a convenient part of a glass slide so that the latter may be capable, through being moved, of unrolling the said figure, animal, or object; or I may use a concealed rod or any other suitable invisible means for causing the said figure, &c., to be unwound. Or I may arrange a figure or the like in sections, hinged to one another, one end being conveniently attached to the said plate, table, or the like, the other end being moved by the means described, or by any other suitable means. Or, again, I may form the said figure or the like in sections so shaped as to be capable of sliding one within the other, and operated in the manner set forth.

Improvements in connexion with Photographs and Other Pictures, and Apparatus for Exhibiting the same.

No. 11,015. John Dewe, Hôtel Métropole, Northumberland Avenue, London, W.—*July* 23, 1892.

My invention relates, firstly, to an improved apparatus for the exhibition of photographs and other pictures, the object of which is to impart thereto a series of natural and realistic effects, capable of being changed or varied indefinitely at the will of the operator; secondly, of a manner of treating or preparing the photograph or other picture to be exhibited therein.

[So far as we can see from a perusal of the specification, this apparatus is the same as we described on page 491 as the "Photo-Chromoscope," which is placed on the market by Messrs. G. Houghton & Son.—Ed.]

Correspondence.

DECLINE (AND FALL) OF PROFESSIONAL PHOTOGRAPHY.

To the Editor.

Sir,—I think the subject you have once more set a-going is well worth being looked at from many points of view, and it would be well that no offence ahould be given or taken because of different ideas on the subject. My experience goes further back than "Professional Photographer," and it teaches me that Mr. Farmer is right advocating technical, practical, and artistic teaching for a photographer. But the past history shows me that the professional is mostly drawn from the ranks of the amateurs. The present and the future is likely to continue the same; and it is no use in trying to raise any objection, for any one may enter the ranks who chooses. But all ought to consider the drift of matters connected with the hobby or trade from which we derive pleasure or profit. Let me give you one or two guesses that are pretty near the truth.

The city that I belong to has, I believe, less than one hundred professionals and operators; it has more than one thousand amateurs; it has about a score of dealers in photographic material, who give hints, lessons, &c., to any one who buys goods from them. Any person can get the catalogues, compare, and buy from the cheapest; get printing, enlarging, &c., done at as low a price as the man who waits on in his glass-house. Then, the so-called amateurs belong to every trade, and they do all that is wanted in these trades. Formerly they used to come to such a one. I could fill a sheet with the names of these trades and professions who used to bring orders to me; now there is scarcely one in a year. "Our young man does it," or "We have a staff of our own."

I don't want to grumble as long as I get just a little; but I would like something better for my family, and I would like to see the profession I have been so long connected with in as good a position as any other profession I see around. What should be done to prevent the decline of professional photography.—I am, yours, &c., Old Pro.

Glasgow, August 16, 1892.

To the Editor.

Sir,—It think that "A Professional Photographer" must have written his letter at, "to put it mildly," "high pressure." Now he has seen it in print, I am sure he will feel that there was much that "might have been expressed differently," and much more that would have better left unsaid. At first sight I must admit that the title of the article complained of, viz., "The Decay of Professional Photography," read rather ominous; but, when read without bias, it dissolved itself into what is commonly called "*hitting straight*" and not "*below the belt*," as a "Professional Photographer" has evidently read it. It is just as well to have a candid friend sometimes, or we are apt to get somewhat conceited, and I think, Mr. Editor, that I am right when I say that this was the vein in which the article was written. To class amateurs "*en masse*" as "plate-spoilers" is palpably unfair, for "photography," and "*photographers generally*," owe much to those gentlemen who have, and do, give time and talents to the working out of photographic problems, and to the discovering of new processes, &c., which are, in nine cases out of ten, cheerfully given to the photographic community, thus at once advancing the science of photography and benefiting their fellow-workers.

There are, of course, amateurs *and* amateurs; I may also add professionals *and* professionsal. Regarding the higher education of photographers, I personally sincerely hope that the time is not far distant when, in every large centre throughout the kingdom, there will be established institutes in which any one wishing to advance with the ever-flowing tide of photographic progress, may have thorough instruction in, say, the photo-mechanical processes, and the higher branches of photography generally; and when the certificates issued from such schools will be the "open sesame's" to good appointments. On whom or what the future of photography depends, time alone will show. But this I can safely predict, *i.e.*, if my brethren of the camera do not advance *with* photography, they will, as our American cousins would express it, "just git left!'—I am, yours, &c., F. J. A.

CENTRAL STOPS.

To the Editor.

Sir,—In the leading article upon "Equalising the Illumination of Negatives" in your last issue, you mention a suggestion, made in 1863, that benefit would be derived from an opaque central stop, suitably placed with respect to a photographic lens. This reminded me of a much earlier instance, where the same device, though under slightly different circumstances, came under my notice, which, with one or two attendant incidents, may interest, and perhaps surprise, some of our younger photographers.

Nearly fifty years ago I spoke to the late able optician Mr. Ross (the first of that name) about making for me a rapid portrait lens. It was, of course, one of the first made, and involved a little consideration, especially as, being young at the time, I was the more concerned about the cost. Ultimately, Mr. Ross told me that, if I would waive objection to some small veins in the flint component of the lenses, he could supply the objective much more cheaply; and that, if I never wanted to magnify the image more than three or four diameters, the veins would be of no consequence whatever. On this understanding, the portrait lens was made. The equivalent focus is somewhere about 6 inches, and the front lens is 2⅜ inches in clear diameter. The largest stop is 1½ inches; and, if a smaller one were desired, it would be needful to unscrew the back lens, and then to *screw* the smaller stop into its place. A Daguerreotype, taken by me soon after the lens came into my hands, proves that *over a small area* (it was intended chiefly for portraits on plates 2½ × 2 inches) the apparent sharpness of the picture could not be exceeded by any

modern lens, and the price charged to me was, I believe, only 3*l.* 10*s.* (I am sure that it was not more than 4*l.* 10*s.*), so that the optician dealt well with me; but for a piece of finely greyed glass, 9 × 7 inches, supplied at the same time, unmounted, for a focussing screen, I was charged 15*s.* It was just such glass as is generally used now for the purpose in good cameras. When copying an engraving, I was often troubled with a "flare-spot" in the middle of the picture, a defect which troubled others also. Mr. Ross told me that some one was proposing to take out a patent for an opaque central stop to obviate this defect, but that Mr. Fox Talbot (the inventor of the calotype process), for whom also, I think, he made photographic objectives, had instructed him to enter a *caveat* against it.—I am, yours, &c.,

CHARLES J. TAYLOR.

Banstead, Surrey, August 15, 1892.

LOSS OF DENSITY IN FIXING.

To the EDITOR.

SIR,—Your very interesting No. (1684), BRITISH JOURNAL OF PHOTOGRAPHY, came to hand, and I consider the group quite a success. On p. 527, the letter headed "Loss of density in Fixing," should read, "Difference of Intensity on a Wet and Dry Plate" I think.

I am sorry, exceedingly sorry indeed, not to be able to oblige Mr. A. C. Manners in his contradiction to my assertion (that a negative is more intense when dry than while wet) and cast my experience of some twelve years, and development of thousands of negatives, to the winds, simply because Mr. A. C. M. has made a trial. I beg to differ, even if he has his opinion supported by his wife and several friends (among them two amateur photographers), to which he may have added his sisters, cousins, and aunts.

I would further say that I have not advanced any theory; I only submitted a fact and tried to explain it plainly. Since then I have not made any unnecessary trials, as I know the fact since years, but have asked several photographers, and they expressed the same opinion as I did.

If Mr. A. C. M. likes to make trials, let him try the following one more conclusive:—Take a stereo negative, and, when developed, print one half of it when dry and the other half while wet, and then see the results in the details particularly. No reproduction of a drawing, but a view with details and shadows.

As to my eyes, they are all right; being able to judge of the *less* or *more* intensity of a negative, there is no reason why I should not be able to judge the *more* or *less*. It may, however, depend upon whose opinion I share as to the value of my eyesight. Hoping you will kindly admit this answer to Mr. A. C. Manners, I am, yours &c.,

A. LEVY.

Asnières, Paris, August 15th, 1892.

NEW DEVELOPERS—A SUGGESTION.

To the EDITOR.

SIR,—I observe from the JOURNAL of last week that another new developer has been placed in the hands of photographers. It appears to me that the experimentalists too closely confine their endeavours to the provision of new developing substances which work cleanly and rapidly at a high degree of dilution with some real or fancied superiority in the control of detail, without, however, enlightening us in regard to the extent, if any, that the new claimants for favour are superior to older reagents in the matter of enabling us to shorten the exposure.

If I remember aright, when hydroquinone was introduced a dozen years ago, it was claimed that, in combination with ammonium carbonate, it enabled one to reduce the normal exposure by one-half. Was this claim ever substantiated? For studio work, this power of shortening the exposure by the use of a particular developer would at times be most useful to possess.

My present object is to inquire whether any comparative experiments have been made with the various developers in actual use with a view to determining which has the advantage of allowing of the shortest exposure, and, if no such experiments have been made, to suggest they be undertaken by some competent investigator. If any developer has that advantage, the information might be of some practical use, whereas at present I submit that the rivalry of new developers is often simply a case of tweedledee *versus* tweedledum; that is, their advantages are more fanciful than real.—I am, yours, &c.,

W. A. WRIGHT.

Ipswich, August 16, 1892.

BORAX *VERSUS* BLISTERS.

To the EDITOR.

SIR,—I think it but right that I should inform you, and also my fellow-photographers, how I prevent the formation of blisters on albumen prints.

Reading up a certain process one day, I noticed that borax was used in the fixing bath, and I thought, Why not use it for prints on albumenised paper? I tried it, and ever since then I have never seen another blister.

My mode of working is as follows:—After toning, the prints are placed in salt water to prevent further toning and then washed under the tap. In the meanwhile a cupful of water is set over the spirit lamp, and when warm enough I dissolve in it an egg-cupful of powdered borax (say, little more than an ounce). This I add to the fixing bath (one pound of hypo to a gallon of water) and stir; then fix for 20 minutes, moving the prints about all the while. Try it.—I am, yours, &c.,

JAMES GRIBBLE.

Art Studio, Pearl, Cape Colony, July 27, 1892.

PERMANENCY OF GELATINO-CHLORIDE PRINTS.

To the EDITOR.

SIR,—At the risk of flattering your correspondent, Mr. H. G. M. Conybeare, I should say that the fact of his gelatino-chloride print having remained unchanged after nine months' exposure to light is rather a tribute to his own careful system of working than to any intrinsic change-resisting quality of the paper. Much severer tests have been applied to albumen paper prints from which they have emerged successfully, and yet nowadays poor old albumen is in receipt of almost universal condemnation.

I like gelatino-chloride prints, but certainly not better than albumen prints, save in certain details of manipulation, and I fail to see where the claimed superiority as regards the properties of the image lies. Would some workers of gelatino-chloride kindly tell me? I don't wish to be told anything about the surface effects, i.e., the enamellike gloss, or the "mattiness." Does gelatino-chloride, for instance, give finer detail or truer gradations than albumen? Is it superior to the latter in printing from thin or dense negatives? Above all, are regularity and uniformity of tone more easily obtainable? My experience negatives those points, but I should be glad to have that of others.—I am, yours, &c.,

Balham, August 14, 1892. R. WILSON.

RESTORING SPENT DEVELOPING SOLUTIONS.

To the EDITOR.

SIR,—Your interesting leader on the restoration of spent ferrous-oxalate developing solutions induces me to ask you or any of your readers whether a method is available for reconverting into usable condition an exhausted pyro solution. Chemically considered, it does not appear to me a difficult matter, while from an economical standpoint a simple and efficient plan of procedure might be appreciated by many workers.—I am, yours, &c.,

Faversham, Aug. 12, 1892. PYROPHIL.

[We are not aware that any such method has been found of practical utility—indeed, looking at the somewhat complex interactions which take place in development, we are doubtful if any "restoration" process could be successfully applied without considerable difficulty.—ED.]

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Will exchange diamond ring, cost 8*l.*, for lens by good maker.—Address, E. SPILLER 107, Lake-road, Portsmouth.

Will exchange fine-toned seven-string banjo in case for half-plate camera or dry plates, &c., value.—Address, H. FLETT, 38, King's-road, St. Leonards.

I will exchange good half-plate portrait lens for whole-plate wide-angle rectilinear.—Address, JOSEPH SMITH, Strawberry Bank, Blackburn.

Five quarter-plate Tylar's double dark slide, with focussing screen, for three 5×4.—Address, J. R. CARDWELL, 79, Crampton-road, Penge, S.E.

Wanted, whole-plate camera and slides, rectilinear lens and stand; will exchange a Beeston Humber Safety, solid, splendid condition.—Address, P., 3, Hinckley-road, Leicester.

Will give two beautiful backgrounds, interior and exterior, also wall background and box for same, almost new, and a little cash, in exchange for Dallmeyer's 2c.—Address, WOMAWELL, Queen's-road, Blackburn.

Wanted whole-plate rapid rectilinear lens (10×8), group ditto, quarter-plate rapid rectilinear, quarter-plate hand camera; will exchange rock accessory, pedestal, posing chair, grass mat, head-rest, Rembrandt vignette background (flatted oil), interior ditto (distemper).—Address, BAILEY, Gordon-terrace, Clovelly-road, Bideford.

Ross No. 2 carte lens, half-plate rapid rectilinear 12×10 bellows camera, two double backs, half-plate ditto, quite new, three double backs and interior background lighted from left; wanted background lighted from right, head and body rest. Studio camera stand and 4-back posing chair.—Address, MANAGER, London Photographic Company, 21 Station-street, Sittingbourne.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," *2, York-street, Covent Garden, London.*

R. H.—Not so far as we are aware of. Why not write direct to the author of the work mentioned?

ALPHA.—Fuse the nitrate of silver at a high temperature, then dissolve in water, filter, and crystallise.

SIGMA.—A developed gelatine negative may be "fixed in gaslight" without setting up any injurious effects on the resulting *eliché*.

ONE IN DOUBT.—A matt surface may be imparted to gelatino-chloride prints by squeegeeing them on to ground glass and stripping before quite dry.

P. B. W.—If the albumenised paper has been kept long in a damp place, the chances are that it has deteriorated, and that would account for the spots.

B. BAILEY. If the negatives be spotted with ordinary water colours, avoiding gamboge, which is soluble in spirit, the spotting will not be disturbed by the varnishing.

W. RIX.—There is absolutely no advantage in the use of a yellow screen with ordinary plates. It materially lengthens the exposure, but in no way improves the quality of the negatives.

DEVON.—If the apprentice's indentures are not stamped, they are of no value. The youth can leave at any time he chooses. On the other hand, his master can discharge him the same as any other servant.

S. T. F.—The quickest way to dry a gelatine negative is to, after draining it, immerse it for a few minutes in strong methylated spirit. It can then be dried at a gentle heat, without fear of the gelatine running.

QUIS.—1 and 2. Take the solids by weight and the liquids by measure, unless the formula directs otherwise. 3. Hardwich's *Photographic Chemistry*, Churchill & Co. 4. *Opties of Photography*, Whittaker & Co.

N. B.—If the sandarac is good, it should make a transparent solution when dissolved in alcohol. There are always some insoluble particles, owing to mechanical impurities adherining to the resin, but they are readily filtered out.

J. LINKLATER.—We are quite unable to give you any information relative to the qualities of the plates named, not having personally tried them. You should apply to the makers. "Cricklewood, London," will be a sufficient address.

H. BOWERS.—Evidently the magnesium was flashed at too great a distance from the sitter. With the quantity of powder burnt, the plate used, and a lens with an aperture of *f*-6, the negative should be fully, if not, indeed, over-exposed.

IGNORAMUS asks: "Can any one register and use for a trade mark a photograph, the negatives of same still being in the possession of the photographer?"—No, providing the copyright in the photograph has been registered by the photographer.

ALBERT FRASER (Chichester).—The double chloride of silver and mercury is unalterable in light, so that in improving the tone of a silver print with a solution of mercuric chloride, as suggested by Mr. Drage, you need not apprehend loss of permanency.

WOOD NAPHTHA.—The new (mineralised) methylated spirit has been employed in the preparation of collodion emulsion with, on the whole, such success as to seriously discount the original belief that it would be useless for that purpose. Heuce our advice to you is to try it.

ASSISTANT.—An attempt was made, a year or two back, to form a trades union among photographers' assistants, but we believe it came to nothing. The Photographers' Benevolent Association is in no way Associated with trades unionism. It is purely a benevolent institution.

M. J. E.—Full details of photo-zincography will be found in the back volumes of the JOURNAL. The process is also described in Hardwich's *Photographic Chemistry*, last edition, and in Burton's work on *Photographic Printing Processes*. There is no separate work specially devoted to the subject.

A. W. WILLIAMS.—The so-called "invisible backgrounds" in Daguerreotypes were obtained by having a background of blanket-like material, placed somewhat out of focus and kept in motion during the exposure. But the same effect cannot be produced on any plate other than a daguerreotype one.

HALOGEN.—In all probability the yellow appearance of the film is due to the presence of silver iodide in the emulsion, but it is better to ascertain the fact by experiment before venturing a positive opinion, inasmuch as bromide of silver alone sometimes assumes a yellow colour not distinguishable from that of silver iodide.

A. S. K.—Carbon tissue is not sensitive enough for producing enlargements direct by ordinary daylight. It may, however, be used for direct enlarging if the solar camera be employed. Carbon enlargements are printed from enlarged negatives; hence they cannot be produced for anything like the price of bromide ones.

OPERATOR inquires: "Will you kindly give me a formula for toning bath that will produce a nice reddish tone, much similar to the red chalk carbon process; if you will assist me in this, I shall feel grateful."—The acetate of soda bath produces good reddish tones, but no toning bath will give tones on albumen paper at all resembling red chalk "carbon" pictures.

A. WEST (Hartlepool).—Sulphite of soda will not only prevent pyrogallol in solution from becoming oxidised, but if added to a plain solution, discoloured to the depth of a sherry tint, will materially decolourise it. In so doing it is probable that it restores the partly lost developable properties of the pyrogallol by deoxidation. The hint may be of practical service to you.

W. WOODS.—If the lens will not take a half-plate negative, sharp to th corners, it is not suitable for enlarging from that size, though it will answer very well for smaller sizes. A lens for enlarging purposes should be capable of taking a perfect negative of the size of the one to be enlarged. The most successful workers generally use one equal to taking a picture one or two sizes larger.

R. H. DAY says he had the misfortune to spill some silver solution on a damask tablecloth, which, he says, "produced unpleasant remarks from my better half every time the cloth is used." He asks if there is any means of getting the stains out?—Make a strong solution of iodide of potassium in water; in this dissolve iodine enough to make it of a dark port wine colour. Treat the stains with this, and afterwards with a solution of cyanide of potassium.

SCOTIA says: "We retouch our negatives before varnishing, and are troubled by the retouching coming off when they are subsequently varnished. As we often send three, four, and five proofs, it is not necessary to varnish those we receive no orders for. I should be glad if you could inform me of any means to modify, if not entirely stop, the removal of the retouching."—Some retouching mediums are more affected by the varnish than others, therefore one should be selected that is least influenced by varnish. The trouble may, however, be mitigated by not making the negative hotter than is really necessary in varnishing.

G. B., JUN., writes: "I have had a difficulty lately, and thought that you might be able to help me towards solving it. It is in the varnishing of wet plates. They are first class immediately before varnishing, but as soon as the varnish touches them they vanish, and almost leave clear glass. I intensify them with mercury. Has this any effect on it? I use Mawson's collodion; also Mawson's varnish."—This is not an exceptional experience. In nearly all cases in which negatives are intensified by mercury, they are rendered more transparent by an alcoholic varnish. It may be well to try the effect of giving them a coating of gum water or albumen, well beaten up, previous to varnishing.

PRINTER writes as follows: "We are often troubled with unsharp prints through the paper not being in close contact with the negatives in places. The springs of the frames are strong, and the paper seems flat enough when first put on the negative, but it seems to cockle afterwards. If the prints, partially printed, are left in the frames in the printing room all night, they are almost always spoilt from want of contact. Can you give any opinion as to the cause?"—The trouble, no doubt, is due to damp causing the paper to expand. If dry paper be placed upon the negative, and then backed with pads that contain moisture, it will be absorbed, and consequently the paper will become distended and buckle. Printing rooms are generally more or less damp in wet weather, and frames and pads left in them all night get moist. See that the pads and backs of the frames are equally as dry as the paper and the trouble will cease.

TYNESIDE CAMERA CLUB.—August 22, General Meeting. 27, Excursion. 29, Council Meeting for winter session programme.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—August 23, Technical Meeting. Subject for discussion, *Portraiture other than in the Studio.*

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—August 25, Members' Open Night. September 1, *Control of Gradation*, W. E. Debenham.

PHOTOGRAPHIC CLUB.—August 24, *Kallitype*. 31, *Optical Glass*. Saturday outing, August 20, Twickenham and Richmond. Meet at Twickenham Station at three to quarter past three.

NEW COLLOTYPE WORKS.—From a circular received from Messrs. Morgan & Kidd, Kew Foot-road, Richmond, we find that they have erected a splendid building, and fitted it up with the most modern machinery for collotype printing.

GREAT CELLULOID EXPLOSION.—A serious explosion of celluloid, lacquer and varnish, and cognate substances took place on the 28th ult. on the premises of the Frederick Crane Chemical Company, Springfield, New Jersey, U.S.A. Not a house within a radius of a mile and a half escaped injury, several buildings being totally destroyed. The presumption is that there were about 500 pounds of gun-cotton in the drying-room; and, owing to the heat of the weather, special precautions had been taken to prevent its heating.

*** *We this week give the key to the Convention Group which we issued with last number. Where blanks occur, or in the event of names being mis-spelt, will any friends able to supply or correct these kindly apprise the Editor and oblige?*

THE BRITISH
JOURNAL OF PHOTOGRAPHY.

No. 1686. Vol. XXXIX.—AUGUST 26, 1892.

INDOOR PORTRAITURE.

This subject is necessarily one of interest to all except professional portraitists, who are the possessors of studios expressly fitted for portraiture. It has formed the theme of discussion at two metropolitan Societies quite lately, and on another page will be found a report of the discussion on the subject which took place on Tuesday at the Technical Meeting of the Photographic Society of Great Britain, and in course of which various phases of non-studio portraiture will be found to have been discussed.

That special phase to which we desire to direct attention at present is one which many years ago, and occasionally since, we have practised with unvarying success. It is a system by which any one who has access to an ordinary bedroom or other window may be enabled to produce a bust portrait which, in respect of roundness, chiaroscuro, and other necessary properties, shall not be in any way inferior to one taken in the most elaborately appointed studio. The window referred to should, by preference, have a northern aspect, although we have found others to serve the purpose quite well so long as the direct rays of the sun do not find admission.

The reader is now supposed to seat himself in front of such a window, and to scan himself in a mirror placed on a narrow table as near to the window as possible. Let him study the effect of the lighting on his face, and then do the same after shifting his chair a few inches to the right or left, noting the different effects produced. In some positions the most perfect modelling will be perceived, and he will conclude that, if a portrait of himself could be obtained just as he is sitting, it would indeed be perfect.

Having established the fact that perfect lighting can be effected, the subject to be photographed now takes the chair, and a suitable background is placed behind him (or her). Its dimensions, colour, and distance from the sitter must be left to the taste of the photographer. The camera is now introduced, and is placed at one side of the subject and facing the mirror in the window, which must now be turned so much to one side as to permit of *its* seeing the reflected image of the sitter, who will no longer see himself, but the camera.

In the duration of the exposure to be given the operator must be guided by experience; but we venture to say that, as he will fail to recognise the volume of light falling on the sitter, and the very small amount of loss by the reflection in the mirror, he will at first err in the direction of over-exposure. In the last trial we made we found that an exposure of three seconds, the sky being overcast with bright clouds, gave a negative which was fully exposed, although the lens, a cemented doublet, was not working at its full aperture. Of course, as every one knows, the rapidity of exposure is determined by the quantity of light by which the sitter is illuminated, and this may be largely influenced by the distance between the subject and the window. We may here observe that the window at which most of our experiments were made measures seven feet in height by three feet eight inches in width, and, if one who seats himself near to and facing even such a small window will measure the vertical and horizontal angle of the light admitted, he will find that it is in excess of that commonly admitted in photographic studios. As we have said on a previous occasion, it is not the size of the studio or its window that determines the force of the illumination, but the angular relation of the window to the sitter. Hence a window which is twelve feet square may in reality admit a far less degree of light, so far as a special sitter is concerned, than one of six feet square, the area of which is only one-fourth that of the previous size. So from this it will be seen that, if a person sits sufficiently near to a window, much more light will fall upon him than would be the case in many studios, and for the same reason it will be seen that, in proportion as he removes his seat from the window, the light diminishes according to the square of the distance.

But what of the double image, the reversion of the image, and the absorption of light produced by a mirror?

Regarding the first—the double image—while there is really a reflection from the front or outer surface of the glass, it is so infinitesimally small as compared with that from the silvered surface behind as to be altogether unworthy of notice. If the glass were presented to the sitter at an angle of great obliquity, then would the front surface of the glass act as a reflector, and a double image would be produced; but we appeal to any one who views himself in a mirror whether such duplication is at all observable. The image from the back or metallised surface is so brilliant as altogether to eclipse the exceedingly feeble one from the front, and as in ordinary practice it cannot be seen, although theoretically there, it may safely be dismissed as an objection.

The image is certainly reversed. This is not a very serious matter in the case of single portraits, while it is a positive advantage if the portrait is to be printed by the carbon or collotype process. But, if instead of a glass plate a celluloid film be employed as the supporter of the sensitive surface, then is it altogether immaterial, seeing that a celluloid film may be printed through, producing either a reversed or non-reversed print at will, and these with practically equal sharpness.

As the light has to pass twice through the thickness of the glass of which the mirror is composed, there will of necessity be some loss by absorption. But what of that? It is only when the mirror is constructed of thick plate glass of a yellow or

brownish yellow colour that influences hostile to the rapidity of exposure may be anticipated, and even then the exposure will only be required to be lengthened to, say, ten or fifteen per cent., an inappreciable quantity when the totality of exposure is under five or six seconds. But with the mirror, with which our experiments have mainly been conducted, and which is known as French plate, the absorption is so little, owing, perhaps, to the thinness and colourless nature of the glass, that we scarcely ever think of estimating it as a controlling factor in the exposure at all.

Without going into further details, we believe we have said sufficient to shew that the system of indoor portrait photography here described is worthy of the attention of those who aspire to this class of work without having other means of carrying their aspirations into effect.

MOUNTING STEREOSCOPIC PICTURES.

On perusing two papers on the stereoscope, respectively by Messrs. A. L. Henderson and W. P. Dando, which appear in the current issue of this Journal, we observe that both stop short at a point which is replete with interest, and one which we make bold to say exercised no mean power in causing binocular photography to fall into the desuetude from which it is only now being slowly rescued. The point to which we allude is the mounting of the pictures.

We fortunately possess a large number of stereoscopic views, the production of which represents nearly all the best-known makers in the world, and, on taking up a few dozen at random, we cannot fail being struck by the great carelessness and utter want of system that prevail in their trimming and mounting.

For facilitating the coalescence of binocular prints in a stereoscope, it has often been shown by ourselves and other writers that the distance apart of similar objects in the stereoscopic pair of pictures should be, by preference, two and three-quarter inches, while never exceeding three inches. But in many slides this distance is exceeded, and, upon accurate measurement, we find it to be in some instances three and three-quarter inches, a considerable number ranging from three and a quarter to three and a half inches apart. The consequence of this is, that many of those slides cannot be brought into coalescence at all, or, if so, it is only at the expense of some pain to the eyes. This is altogether avoided by confining the amount of separation to the measurement we have given. While the width apart of the pictures is of such vital importance, it is not so with regard to their height, as in this case the eyes may have full play in a vertical direction.

Where carelessness is very often apparent, even when the correct distance between the pair of pictures is preserved, is in the manner in which the sides of the prints are trimmed. It is first of all imperative that the base line be identical in both halves. This is easily ensured by selecting a point in the foreground of one print, and laying a straight edge down so as to cut this and the corresponding point in the companion print, and then trimming them to that line.

Next take one of the halves of the binocular pair, say that which is to be mounted at the left-hand end of the card, and cut it so as to include so much of the subject as is required to make a pictorial whole. Where skill is required is in the trimming of the second element of the pair. Trim first the right-hand side of the print, taking care that any object at that margin of the foreground shall be shown slightly fuller than the corresponding object in the previously trimmed half, that is, that rather less of it shall be shown in the right picture than in the left, and then cut them both of the same width. It follows that there will be *slightly* less subject (measured from foreground—this is essential) visible at the extreme ends of both prints than where they join in the centre of the mount. The effect produced by this is that the subject appears in the stereoscope as if projected beyond the mount, and this is the way in which all such pictures should be mounted. Out of fifty pictures exhibited at a photographic meeting lately, including works by all the leading professional makers of Europe and America, it is worthy of notice that none but those of Mr. W. I. Chadwick were correctly mounted. This speaks volumes for his care and attention to details.

PHOTOGRAVURE AND AQUATINT ENGRAVING.

In an article a fortnight back we treated on one method of producing photogravures by which the intaglio plate is formed by the deposition of copper by electrotyping on a grained gelatine relief. Now, although that method is extensively employed by some firms, it has, to a considerable extent, been superseded by another, which is known as the etching process. The advantage of the latter over the electrotyping system is mainly that of expedition. To produce a plate of sufficient thickness for printing from, by electrotyping, will occupy something like a fortnight; whereas, by the etching process, it is a question of minutes rather than of days. It is to this system of working and its principles that we shall here direct attention.

The modern method of photo-etching is founded upon that first invented by Fox Talbot now some five-and-thirty years ago, and by which that gentleman produced results that would not suffer in comparison with many of the untouched ones of the present day; indeed, the process differs by little from the original one. Talbot's method consisted in coating a copper plate with a thin film of bichromated gelatine, then exposing it to light behind a transparent positive. When the image was sufficiently printed, the plate was treated with a solution of bichloride of platinum, or with one of perchloride of iron. The solution penetrated the film in proportion as it had been protected from the light's action, and attacked the metal, and so etched or "bit" into it. The present system is conducted somewhat differently, inasmuch as, instead of etching through the film just as it leaves the printing frame, the unacted-upon-by-light portions are dissolved away by warm water, so that there is no gelatine at all on the deepest shadows.

If we take a carbon print, made from a transparency, and develop it on a copper plate, and, after drying it, immerse it in a solution of perchloride of iron, the copper will commence to dissolve at once where it is not protected by the gelatine, and gradually in the other portions as the solution permeates the different thicknesses of the film of which the image is formed. Hence, in the end, we obtain an intaglio image in the copper with perfect gradation from the deepest shadows to the highest lights. But, if a plate so produced be printed from, as an engraved plate would be, only an exceedingly poor print would be obtained, because, notwithstanding that the image is in intaglio, it has no ink-holding properties. Indeed, it would be very similar to an electrotype from a plain gelatine relief, as referred to in the previous article. It is necessary that the image not only is in intaglio, but that it also possesses a grain or "tooth," otherwise it will not retain the ink when applied, as in copper-plate printing.

Photographic etching, as carried out in practice, is very

analogous to aquatint engraving, except that the varying thicknesses of gelatine of which the image is composed take the place of the different stoppings off and re-etching processes.

The process of aquatint engraving, it may be explained to those who are not familiar with it, is this: On a copper plate is laid what is called an aquatint ground. There are two methods of doing this. One is to flow over the plate a solution of common resin, sometimes with the addition of Burgundy pitch or other resins, in alcohol, in the same manner as collodion is applied to glass. As the film dries it "chills," as matt varnish does. If this coating be examined with a magnifier, it will be found to contain numberless minute cracks or fissures which expose the bare metal. The more general way, however, is to dust the plate over with a powdered resin or bitumen, and then heat it until the material is just melted, and thus becomes fixed to the metal as fine particles. This latter, by the way, is the plan generally adopted by photo-etchers. If a plate thus prepared were put into a mordant in which the metal is soluble, it would be dissolved or etched out in the minute spaces where it is not protected by the resinous matter. Of course, if such a plate were inked up and printed from, it would yield a perfectly black impression, just as would the mezzotint-grounded plate referred to a fortnight ago. When a perfect ground has been laid, the engraver paints in the high lights with an acid-resisting varnish, and then treats the plate with dilute nitric acid for a short time. Then, after washing and drying it, the delicate portions are painted in and the plate etched again. These operations are repeated again and again until the deepest shadows are reached. These, of course, will have been exposed to each of the many etchings.

Now, it will be seen that photo-etching, except that it is worked, so to speak, automatically, is analogous to aquatint engraving. An aquatint ground is laid, either with powdered bitumen or resin, on a copper plate as just described. In Talbot's original process the ground was laid on the surface of the gelatine film after the image was printed. A carbon print is then developed upon it. When dry, and after its margins and back have been protected with an impervious varnish, the plate is immersed in a solution of perchloride of iron. Nitric acid, as used by engravers, could not be used, as it would act on the gelatine. The perchloride at once begins to etch the deepest shadows. It then slowly penetrates the gelatine in the thinner parts, and etches there. Afterwards it reaches the half-tones, and finally the high lights, when the action is stopped.

From the above it will be seen how very similar is photo-etching allied to aquatint engraving. The highest lights which the aquatinter forms with his first application of varnish is represented in the photograph by the greatest thickness of gelatine. The middle tints, which may, perhaps, be reached by the fifth or sixth stopping out, is in the photograph represented by a medium thickness of gelatine, and so on. Aquatint engraving is a somewhat tedious operation, owing to the many stoppings out and re-etchings. But, as we have said, with photo-etching the work proceeds almost automatically, by reason of the varying thickness of the gelatine film of which the image is composed.

In the foregoing remarks, *a* solution of perchloride of iron has been spoken of; it may be mentioned, however, that, in practice, solutions of several strengths are employed for the same plate. A strong one is used first for the deepest shadows, a less concentrated one for the lighter ones, and more dilute ones for the delicate tints. It may also be explained that a strong solution of the perchloride of iron will take a long time to permeate even the thinnest portions of the gelatine, while a dilute one will penetrate through the thickest parts, and attack the metal rapidly. A concentrated solution of perchloride of iron has a hardening or tanning action on the gelatine, while a weak one has not.

Artistic Photographs.—Our contemporary, *La Nature*, reproduced the other day a set of photographs exquisitely graceful and artistic by means of a wood engraving from phototype prints in the *Journal* of the Photo-Club of Paris. The editor very justly and pertinently remarks that formerly it was a reproach to photography that it was in no sense artistic, that it presented to the painter nothing but a purely chemical process and mechanical reproductions—a reproach that was just in a certain measure when referring to the work of unskilful operators devoid of taste. But, when the worker possessed artistic sentiment, he produced works of art that would do credit to the most careful painter. The illustration, four studies of a child blowing bubbles, by M. Boissonas, of Geneva, a name well known where art and photography are allied, bears out in every way this thesis.

Decolourising Shellac Varnish.—For more years than we can remember, the plan of shaking the varnish with animal charcoal and placing in the sun has found a place in almost every receipt-book and text-book on the subject. We have tried it more than once with just as much decolourisation as would be produced by reading aloud to it Campbell's *Pleasures of Hope*. No, the attempt is hopeless, and we recommend our readers to have none of it. If they require a pale (not a colourless) varnish, let them use bleached shellac. But there is no reason why for varnishing negatives a pale varnish should be used. Ordinary unbleached shellac gives a tougher and stronger body, and, as to the colour it imparts to the negative, it is far less than the normal excess beyond what is unavoidable that characterises ninety per cent. of the average dry-plate negatives.

Shellac Varnish.—In making this indispensable requisite for the photographer an amount of waste takes place that is almost sad to contemplate. The solution is made, the vessel is allowed to stand, say, for a month, without agitation, and the varnish is decanted. But how much varnish? Very little more than one-half of the whole quantity. The rest is hopeless mud, from which but a comparatively small proportion of clear solution can be removed by filtration. The drysalter can use this up for "French polish;" but what resource has the photographer but to throw it away, with a feeling of regret at the absolute waste? He can utilise a portion by thickening it with a further addition of shellac for a strong varnish for woodwork; but he is not likely to use much in this way as the waste continues. All kinds of methods for depositing this insoluble matter have been proposed—the addition of all sorts of insoluble powders, to cause it to settle, for example—but with little practical advantage so far. A suggestion recently made to us seems very feasible, and if any of our readers in possession of the required apparatus can, and will, attempt it, we should be pleased to hear the result. The suggestion is that the varnish should be cleaned by placing in a centrifugal separator.

Methylated Spirit.—Last week we concluded our *résumé* of the method of procedure to be followed in obtaining the old kind of spirit by the warning, *inter alia*, that the purchaser should, "above all, take care of all papers in connexion with its purchase and receipt." We may particularise still further with advantage upon this last item. We have explained how, to order the spirit from an authorised methylator, it is necessary to fill in a form and counterfoil and send the former on to the maker. The latter also has his share of formality to go through. He has to obtain a "permit" to deliver this duty-free spirit, and it is in the form of a small slip of paper. This slip, or "permit," is always attached to the vessel in which the spirit is sent out (usually tied to the label), and should be preserved so as to be open for the surveyor's inspection when he pays one of his periodical visits. A special warning circular is usually sent to holders of a permission to purchase oil-free spirit, and contains the following

clause: "The purchasing of spirits of wine from others than licensed dealers and retailers, or the receiving thereof unaccompanied by the permits and certificates required by law, subjects chemists and druggists to heavy penalties, and renders them liable to detection from various sources." Our readers should substitute the word "photographers" for "chemists and druggists." *Verbum sat sapienti.*

Cui Bono?—It has been suggested to us that, as an answer to those who preach "practice before theory," and are always putting the trite question that heads this paragraph when purely experimental work is in question, we should give some of the concluding sentences of the opening address of the President of the Chemical Section of the British Association, a portion of his remarks referring to catalysis having already been quoted by us. Premising that the coal-tar dyes, mauve and magenta, were the outcome of purely theoretical investigations, and that their manufacture in the early days of the industry brought, by repute, a fortune of over a quarter of a million of money to the fortunate workers of the patent taken out for the production of these dyes, we give Professor McLeod's own words (photographers might read "emulsion plates" for "mauve and magenta," and the lesson would be complete):—"Need I say more? The moral of mauve and magenta is transparent enough; I read it in your eyes. We understand each other. Whenever in future one of your chemical friends, full of enthusiasm, exhibits and explains to you his newly discovered compounds, you will not cool his noble ardour by asking him that most terrible of all questions, 'What is its use? Will your compound bleach or dye? Will it shave? May it be used as a substitute for leather?' Let him quietly go on with his work. The dye, the lather, the leather will make their appearance in due time. Let him, I repeat, perform his task. Let him indulge in the pursuit of truth—of truth pure and simple—of truth, not for the sake of mauve, not for the sake of magenta; let him pursue truth for the sake of truth."

CONVENTION JOTTINGS.—V.

A Run through Some of the Scotch Studios.

Alex Ayton, Jun. (Brunstfield-place, Edinburgh).

Mr. Alex Ayton's studio at Brunstfield-place, Edinbugh, is a complete establishment, which proves how, with method and management, a large trade can be done in a limited space, for the space in this case is limited when the large amount of business done in it is taken into consideration.

Having acquired all the open ground available on the site that, as a favoured position, has proved such a remarkable success, Mr. Ayton can get no farther, and so has to content himself with the extent of premises at his command.

One advantage he possesses, and that is the whole of the business premises and studio being on the ground floor, which, in a city like Edinburgh, counts for a great deal, so many people having an aversion to stairs.

The frontage of Mr. Ayton's place is all that could be desired, possessing as it does two large windows to the street, where the show of work is prominent and pleasing, and, as a means of advertising, invaluable. The doorway, artistically fitted with stained glass, is situated between the windows forming the entrance to the showroom, which, on entering, we find crowded with examples of the various kinds of photographic work produced in the establishment. Amongst these specimens the group photographs stand out prominently, Mr. Ayton having made a specialty of this class of work, and, with his constant practice, has attained considerable perfection, both in technical excellence and general artistic arrangement, which is quite marked.

The Convention Group being one of many in a collection where groups are on view of many hundreds on one plate, all seemingly steady, artistically arranged, and fully exposed.

Platinotype forms a considerable part of Mr. Ayton's business. It will be remembered that at the Edinburgh International Photographic Exhibition a medal was awarded to him for this class of work, and his exhibits of large platinum work, shown at the Glasgow International Photographic Exhibition, gained considerable praise and attention.

Going from the showroom to the studio, the dark rooms are arranged along the one side, and the dressing rooms along the other aide, of the corridor, the studio itself being profuse in furniture and fittings.

For the purpose of gaining distance when required, here we found a novel arrangement employed, whereby the end of the studio can be removed, and by this means any convenient distance obtained.

The electric light for portrait work has been a study of Mr. Ayton for a long time past, and his many engagements at fancy balls and bazaars during the winter, where the electric light was the only illuminant used, has given him considerable experience and practice. A reflector used by Mr. Ayton, and which he considers gives him better results than the bell pattern, is an upright reflector of cardboard or white cloth, concave shape; by this style of reflector he feels that he gets a more diffused light, giving softer pictures, and with less pronounced shadows. When it was suggested that considerable light was lost by this style of open reflector, he felt that it was so, but that it did not interfere with the obtaining good results in a reasonable time.

He has also got the bell arrangement fitted in his studio, which he works along with an open light, so arranged as to lighten the shadows.

The engine-room is built alongside the studio on a lower level. A seven horse-power engine is what he uses.

The whole of this establishment is compact and complete, and the work turned out cannot but command approval and success.

Mr. Moffat (125, Princes-street, Edinburgh).

When visiting Mr. Moffat's studio, our memories went back to the time when, in the "positive" days, at a photographer's in the east end of Princes-street, a single picture was shown in a showcase all alone. It was about whole-plate size, as far as our memory serves us, and the subject was a scene from Tom Taylor's "Still Waters Run Deep," the characters being represented by Tom Mead and Charles Moorhouse. And what a sensation that single positive picture created at the time! That was Mr. Moffat's production, and hundreds of people flocked to see it. Doubtless it proved a profitable advertisement, but these were other days. The charm of the "positive" was upon us then; it has passed, and many are the processes that have to be tackled now if we wish to keep abreast of our fellows. Yet still we do not believe that any one picture by any of the processes of the present day would produce the universal admiration that the good old "positive" did in its time.

Now, at 125, Princes-street, on our visit, we find that, with the same energy as of yore, all branches of photography being worked and produced in Mr. Moffat's premises, the sons, following in the father's footsteps, undertaking the more active parts of an ever-increasing trade.

This business has so outgrown the premises at 125 that all the upper floors over the shops in 126 have had to be added to it, thus pretty well doubling their working accommodation. On the first floor there are three reception rooms adjoining each other; in these rooms an endless series of pictures are shown, illustrative of any kind of photographic work.

As a special feature, portraits in oils, from small up to life size, form the examples of one of the reception rooms.

Drawing on canvas from the negative is the method they use mostly, and which they consider best; but this means getting rid of any photographic basis, which is so liable to go wrong.

Specimens of flashlight pictures by the Slingsby arrangement were on view; also the latest group of the season—that of the Lord High Commissioner and party. Enlargements up to five feet, and direct pictures up to thirty inches, are here shown.

There are two studios in constant use, and the rooms, from the reception flat to the top of the building, are all utilised in developing some branch of the photographic art. In one of these departments we saw platinum pictures in dozens being developed by the hot-bath process, Mr. Moffat preferring it to the new cold-bath paper. Going up flat after flat till we reach the little balcony over the house-top,

we get confused and mixed, the only idea that keeps prominently before us being that here a great trade must be done, if only to cover the working expenses of the establishment.

All along the line Mr. Moffat keeps up to the times, and now, with two sons in the business—one essentially devoting his attention to the artistic department, and the other, with his many years' experience, in all the higher grades of the art-science—makes us feel that progression must be the natural result.

Mr. Crooke (103, Princes-street, Edinburgh).

Mr. Crooke's studio bears the impress of the man from the entrance way, of a cream and gold, right through the whole of the premises. The decorations, furniture, and fittings are original, and peculiarly his own. The "Judge" pictures, and many others of varied subject, from their original conception are familiar to us all. We felt the same with regard to his surroundings, they possessed an individuality as pronounced as are his well-known pictures.

In his studio there is not a door, a window, a fireplace, or a panel in the wall that is not turned to photographic utility, and becomes in his hands an accessory used in the production of artistic effects in pictures. Even the stairway to the studio is utilised upon occasions for groups and other artistic effects.

The studio is so arranged that pictures can be taken in any part of it, and the background can be moved to the sitter if a part of the ordinary fitting of the room does not answer the purpose required.

The upright light of the studio is a casing of glass, which runs along all the length of the apartment, and plants are growing between the front and back glass frames. The glass is fitted in panels of various patterns, and curtains are arranged in front of these, so that, in the composing of pictures, many charming effects of light are obtainable.

The doorways to the rooms that lead from the studio are all carved on the patterns, with elaborate designs at top, so constructed that they may form part of a picture at any time.

There are two fireplaces in the studio, the mantels and surroundings of which are also arranged with an eye to picture-making.

The walls all round the studio are fitted with old oak panels, and carved in beautiful designs. These also play a considerable part in the production of pictures.

In fact, everything in the place seems to have been thought out and arranged to answer the double purpose of being in itself a thing of beauty and a useful appliance in the prosecution of picture-making. The class of work produced by Mr. Crooke is so well known for its artistic excellence that comment upon the same is unnecessary.

Mr. Crooke was one of the first to push forward the claims of platinotype as being a process that was capable of producing the most artistic results, and by the beauty of the examples which he is constantly issuing he has certainly proved that his confidence was well placed.

The medals that have fallen to his share in the places where he has exhibited show that his pictures are appreciated far and wide, and that the name of Crooke on any exhibits is synonymous with an artistic production.

JOTTINGS.

It is a singular and perhaps felicitous coincidence, that concurrently with the publication of your leading article on "Exhibitions, Old and New," in which you give expression to the general rumour concerning the projected swagger photographic exhibition in Piccadilly that is to take the artistic world by storm and supplant that of the poor old Parent Society in public estimation, Mr. H. P. Robinson, in a contemporary, should take up a position before the walls of Jericho and blow his penny trumpet, with the expectation, or at least the hope, that those walls (i.e., the Photographic Society of Great Britain) will forthwith tumble down. Rumour, then, is, as you surmise, correct, and the rival exhibition is to take shape. Naturally the photographic world will be curious, and possibly anxious, to have the *raison-d'être* of the exhibition; and, as Mr. Robinson has evidently been put up (or has put himself up) to supply it, it will be interesting to find out whether that reason or reasons are of a nature to merit the applause of any body besides Mr. Robinson and his friends. Let us see.

Mr. Robinson's effusion is a bitter attack on the Photographic Society of Great Britain and all its works, with one exception, and that a remarkable one, the President, to wit, who is "an earnest student," "a master in science," and so forth. The President (who is also, by the way, President of the Camera Club, Mr. Robinson's new-found refuge) occasionally gives "real science," which Mr. Robinson confesses he does not understand. How, then, does he presume to distinguish between "real" science and the other thing? Not only is "scientific pedantry rampant" among the Society, but the meetings are "distinguished by dulness" (*sic*); the "platitudes of rudimentary science are discussed by the usual half-dozen members," while "art has for years been scarcely mentioned." Granted; but I should like to put to Mr. Robinson a question of a similar kind to that which I put to his companion in attack, Mr. W. Jerome Harrison, a few weeks ago, and this is: Did Mr. Robinson only discover these things when the officials of the Society refused to allow him to hang his pictures where he liked? If so, he was blind and deaf for several years; if not, how very strange that he was content to enjoy membership of such a Society so long! Was it because he always had things pretty much his own way at exhibition times that he was content to keep silence while this "merest trifling" went on?

Our critic graciously allows that the Society's exhibition was of use in former years. Clearly, for did it not provide Mr. Robinson with a trayful of medals? But the exhibition only exists now "because it pays"—the Society, of course. Did it only exist formerly because it paid—Mr. H. P. Robinson? The distinction between Mr. H. P. Robinson and the Society by Mr. H. P. Robinson is a very pretty and instructive conceit—instructive, because it is the key to the situation. The exhibition *now* "consists principally of pictures, or *so-called* pictures" (my italics), and, as no experts have been appointed to judge these pictures (or so-called pictures), some of those exhibitors who care for and respect their art will not exhibit this year. Besides Mr. Robinson himself, only Mr. Davison, so far as anybody knows, will be absentees. Are these gentlemen the "some?" Again, the system of judging in vogue this year will be practically identical with that under which Mr. Robinson obtained a large percentage of his medals, and what I want to know is why, as he ridicules that system, he accepted those medals over a period of thirty years?

The proportion between picture-makers and others on the Council of the Society comes in for analysis at Mr. Robinson's hands, and as there are only one or two picture-makers and a picture-copier of the first class upon it, and few who have exhibited at all, Mr. Robinson exclaims derisively, "From these are selected the judges of art!" But where on earth did Mr. Robinson imbibe the eccentric doctrine that a judge of art should himself be an artist? Competency to judge the qualities of, say, a beefsteak does not imply that the judge should necessarily be a butcher. Is Mr. Ruskin an artist? If the Society's judges, or some of them, in former years were not artists—and therefore not competent, according to the Robinsonian theory, to act—we must take it that some extraordinary blunders in the awards have been made, and that medals were given to the wrong people. Admitting the truth of Mr. Robinson's arguments, to how many of his Society's medals was Mr. Robinson justly entitled?

Mr. Robinson ingeniously tails off his article by pleading that the line should be drawn between the scientific and artistic branches of photography, and thence, with equal ingenuity, glides into a favourable word in advance for the "new exhibition." Exhibitions worthy of the art are what he wants; for it is preposterous of the Photographic Society of Great Britain, which snubs art (in the person of Mr. H. P. Robinson), to ask artists (that is, Mr. H. P. Robinson and Co.) to supply it with pictures for an annual show. Let the artists have an exhibition of their own. Hooray! They *will* have it next spring in Piccadilly, where Mr. H. P. Robinson will be able to place his own and his friends' pictures in the best positions, and get good big gold medals; the band will play, the policeman will be conspicuous by his absence, and the millennium of photographic art will be reached at last. So I say again, Hooray!

By the way, is it not an extraordinary circumstance that the below-the-belt attacks to which the Photographic Society of Great Britain has lately been subjected, should have emanated from two men who found to their cost that the Society was not disposed to consent to playing the *rôle* of stepping-stone to their personal aggrandisement and self-glorification — Mr. H. P. Robinson and "Talbot Archer?" A little bird whispers to me that my *exposé* of the latter individual has taught him a salutary lesson, the moral of which, I hope, will not be lost upon the former. So long as the Society's enemies are of the class of Messrs. H. P. Robinson and "Talbot Archer," it has nothing to fear. They only advertise it effectively, while at the same time they injure nobody but themselves.

Poor Mr. H. M. Hastings! What have you done to induce the Editor, in the key to the Convention group, to miscall you "Bickersteth?" I do not know who "Bickersteth" is, but to be mistaken for one whom I have heard called "the King of Hand Camerists" is an honour of which he may be proud. Never mind, Mr. Hastings; nobody will be misled by the error of nomenclature, for everybody knows Mr. H. M. Hastings in a picture, no matter how he is named.

COSMOS.

THE STEREOSCOPE AND STEREOSCOPIC PHOTOGRAPHY.

[Lewisham Camera Club.]

STEREOSCOPIC photography, which for several years after its introduction was an absorbing passion, afterwards, for some unaccountable reason, got under a cloud; but I am glad to observe that it is now again being presented, for it has very much to recommend it.

A stereoscopic picture differs from an ordinary one in the same degree and to the same extent as does any scene or object in nature when viewed with two eyes or with only one. In the former case we have the power of discriminating the relative distance of one object from another by the axis of the eyes having to converge to a greater or less degree, according to the varying distances at which objects are from the camera or point of sight from which they were taken. The two halves of a stereoscopic picture are the same, yet different. If you stretch out your arm and hold up one finger, you will find that on viewing the scene before you, first with the right eye and then with the left eye, the finger cuts a different part of the background with each, and that when looking with *both* eyes at the distance you are conscious of the finger being duplicated, whereas, when by converging the eyes you look at the finger, the distant objects are duplicated. This applies to every object, from that in the nearest foreground to extreme distance.

A binocular camera reproduces what the eyes see, and a stereoscope permits of these two similar, yet dissimilar, pictures being combined in the brain with all their different distances made apparent. This is the general principle of stereoscopic photography and the stereoscope, a term composed from two Greek words signifying, "I see solid."

The first stereoscope was one invented by Professor—afterwards Sir Charles—Wheatstone in 1838, who then explained its theory to the Royal Society. It was described as being intended for exhibiting two plane perspective views of an object taken from different stations, as one having the appearance of solidity. In this instrument two small mirrors placed V-shape form what is now the eyepiece, and the right and left-hand pictures are placed respectively at ten or twelve inches on either side, so that, when each eye is directed upon a slope of the mirror, it sees the picture which is reflected, and which may be one of dimensions very greatly exceeding those necessitated by the use of the modern stereoscope. It was imperative that pictures for the Wheatstone instrument had to be mounted singly.

The modern stereoscope was invented in 1849 by Sir David Brewster, who, in seeking to devise a means for superseding the bulky and cumbersome apparatus of Wheatstone, devised the lenticular stereoscope so well known by every one at the present day. In it the pictures are mounted side by side on one card, and are viewed by lenses of similar power, so arranged that the eye is directed to a portion situated between the centre and the edge.

The first stereoscopes of Brewster had eyepieces formed of a single lens of about six inches focus divided into two by being cut across with a diamond, and each half then trimmed into a round shape. The thinnest sides must be mounted to be next each other. When a pair of pictures are viewed through such an eyepiece, both are brought together, and form one image which is composed of the two.

Some idea may be formed of the importance of the stereoscopic business several years ago when I say that, in looking over an old book of photographic patents, I find that between the years 1860 and 1866 something like thirty-four new inventions in connexion with this instrument are recorded as having been introduced. These had reference mainly to mechanical improvements in the construction of the case, or the means of adjusting the lenses without affecting the principle of construction. One of them, however, deserves special mention. It was a pedestal stereoscope, containing several dozens of transparencies, the peculiarity being that, after a sufficient time had been allowed the spectator to examine the picture, it began slowly to fade away, another view gradually taking its place and increasing in brightness in proportion as the former one grew dim, precisely as the dissolving views are shown by a pair of well-managed lanterns. This stereoscope worked automatically by means of clockwork.

Undoubtedly the American hand stereoscope, invented by Oliver Wendell Holmes, the well-known author, is the simplest and best that has yet been introduced, at any rate for viewing slides printed on paper, although it is not so well adapted for transparencies as some others. The light is admitted to the slides from all sides, which obviates the necessity for the irksome dodging of the head required in the illumination of the picture in those with solid closed doors, as in Brewster's.

Stereoscopes of the American type, provided with achromatic eyepieces, and having all required adjustments, are now being made by enterprising specialists, and by the agency of such instruments stereoscopic pictures may be examined quite free from such imperfections as prevail with imperfect instruments fitted with imperfect lenses. Some examples are here submitted for your examination. Mr. J. Traill Taylor has shown, in articles on the Stereoscope published some years since, how that, by means of achromatic eyepieces of short focus, stereoscopic slides of the usual small size may be shown in the same apparent dimensions as the large pictures, which could only be exhibited in the extinct Wheatstone reflecting stereoscope.

Concerning the camera for taking stereoscopic pictures, little need be said. In former days, when so many confined themselves to this class of picture alone, the camera was made of the exact size of the slide, but photographers now prefer the option of taking either a pair of pictures by a movable partition, and a binocular front, or a single view covering the entire plate. For this reason the ordinary half-plate camera is much employed, although some prefer the original half-plate, formed by cutting a whole-plate exactly in two, or, as it is termed, the double quarter-plate. This latter size is advocated by Chadwick, who has devised a curtain roller division, capable of being extended to suit lenses of any focus, and of being quickly detached when a single view is wanted to cover the entire plate. An incidental advantage of this size lies in the fact of quarter-plates being more readily procurable than larger ones from dealers in small towns when one is away from home and happens to have exhausted his stock of plates.

As with cameras, each must please himself with regard to the lenses he uses; if they are to be five inches and upwards in focus, single lenses will answer quite well, even if the subject be an architectural one. A much shorter lens than this may be used for landscapes; but, if tall buildings of wide angles are wanted, then is it desirable that a non-distorting or rectilinear one be preferred, for, although the eyepieces of a stereoscope correct much, and, in some cases, all—distortion, yet as so many now use the half of a stereoscopic negative for making lantern transparencies by contact printing, it is as well to have them as perfect as possible. This must be held as applying not to landscapes, but only to buildings when using lenses of short focus.

Care must be taken that the stops of the lenses be of exactly equal size. As in every other kind of camera work, a quick-acting shutter should be fitted to the lenses, having an arrangement for keeping them open for a long exposure, such as is required in interiors, church interiors in particular.

Various methods have from time to time been advocated for producing stereoscopic effect upon a screen with the aid of a lantern. An ingenious device has been invented by Mr. Field, and described by Mr. J. Hay Taylor in the current number of the *Optical Magic Lantern Journal*, from which I will quote:—

"One of the two slides prepared from pictures taken by a stereoscopic camera is placed in one lantern, and the other slide in a second lantern. Into the optical system of each lantern is introduced a Nicols prism. A number of glass plates are placed at the requisite angle for producing polarisation by refraction, and enclosed in a convenient case or frame. These plates are so arranged in each lantern that the light from one will emerge polarised in a plane at right angles to that emerging from the other. The images of the two slides or pictures so polarised are projected and superposed on a screen, and are viewed by the observer through a pair of analysers of any construction capable of effecting the requisite

amount of analysation, and these are set with their planes of polarisation at right angles to each other. One analyser will permit the image of one of the pictures—the one polarised in the same plane to pass through to the eye, whilst the second picture, polarised in a plane at right angles to it, will not pass. With the second analyser this order is reversed, the image of the picture stopped by the first analyser passing through it, whilst the other is stopped. Therefore upon each eye of the observer the image of a different picture falls, and, as the two pictures are as nearly as possible superposed on the screen, an image of one stereoscopic picture falls upon the retina of one eye, and an image of the second stereoscopic picture upon a corresponding portion of the retina of the other eye. The conditions being fulfilled under which stereoscopic vision of two pictures is possible, the one picture seen appears in relief.

"The analysers designed for this purpose are made of a number of thin glass plates, and the necessary polarisation is effected by refraction. These glass plates are set at a proper angle in a mount resembling a very small opera glass or any other form more convenient.

"The plates are arranged at slightly varying angles to each other in the same plane, for, if a number of plates be placed flat one upon another, around the principal image a number of fainter images are formed, and thereby the definition or clearness of the principal one is impaired. By arranging the plates as described a well-defined picture is obtained."

On the table you will see a large collection of stereoscopes, kindly lent for the occasion by Mr. W. I. Chadwick, of Manchester.

ADVANCED PHOTOGRAPHIC WORK FOR AMATEURS.

VIII.

In a former article I referred to the blocking out of printed images on paper previous to toning and fixing, with the view of enabling the removal of undesirable backgrounds and the substitution of others; and, doubtless, no sooner will a keen worker have succeeded in producing such simple transformations than his mind will at once be struck with the very wide range of operations that become possible by means of such manipulations. I propose just to notice a few of these.

We are almost daily meeting with cases where amateurs desire to name their prints. In this respect there is a distinct desire shown to copy professional brethren, or it may be to merely impress a print with one's initials; for, doubtless, when turning over an album a well-arranged system of adding the names to the prints, whereby even a stranger may gather a knowledge of what the view represents, is most desirable. Hence every now and then we find writers describing methods of adding such names, and in nearly every instance the instructions given are, to subject the *negative* to some treatment, such as by printing backwards on the film, whereby the opaque letters will print white on the sensitised paper. More recently, special reversed types have been introduced by an enterprising firm for this purpose; but all such methods involve the preparation of the negative, and not one in a thousand is clever enough to cut, write, or print backhanded, whilst not a few fastidious gentlemen send their negatives to expert lithographers to have such titles printed on them. Now, all this means trouble, and expense, and, further, does not tend to improve a negative. I have often smiled at the ignorance displayed by amateurs when talking over how beautifully Armstrong writes backwards on his negatives; for, if the truth must be told, I could no more write beautifully backwards (or forwards, sometimes, either for that matter) than I could jump over Ben Lomond.

Others, again, recommend adding such titles to negatives by a system of transferring from the surface of other papers or suitable films, so that the negatives receive an impress from ordinary writing, but in reverse form.

Now, for amateurs merely, or in cases where an odd print now and again has only to be thrown off, there is really no need for any such trouble or bother. There is a far easier and better way whereby *any one* may throw off a print bearing the impress of any name or title that may be desired, and, once a worker experiences how simple and easy it is to name his prints in this manner, he will never dream of subjecting his negatives to any treatment.

This is the way to go about it: Take the pen you are accustomed to write with, and, having prepared a solution of Indian ink not just so thick as that provided for blocking-out purposes as previously described by me, and in a dull light, take the piece of sensitised albumen paper it is intended to print, and proceed to write on its surface on the exact spot you wish the naming to appear in the finished print. This is best done on the shadow portion of the picture, because the white lettering will then stand out in bold contrast. Having written the naming, or whatever else is desired, such as a special number or one's initials, place the sheet of paper carefully aside for a few minutes to dry. Do not attempt to blot it off, but let it dry of its own accord, and when thoroughly dry place the paper in contact with the negative, and print and tone as usual, rubbing off gently the black lettering in the first washing water.

This method is the one practised by most Continental photographers, and has the advantage of not tampering with the negative, and therefore permits of any alteration of title, or number, or initials that may be desired from time to time.

Once a worker enters fully into the advantages of blocking-out and working by opaque means *on the surface of the print*, he will have his eyes opened to much that previously puzzled him in many things photographic, such as lantern slides where transparent lights are relieved by opaque grounds on the screen, and many other similar uncommon results. But perhaps there is no more interesting application of this kind of working than to what is known as combination printing. A great many workers have an idea that a combination picture is necessarily a work of great difficulty, and one that requires the utmost skill in the preparation of a special negative or negatives for its production, and very likely will have formed some extraordinary ideas about the necessity of being able to work the collodion process, and further, to be an adept in the use of iodine, &c., and the floating off of one film so as to place it over that of another, before there be any possibility of producing a combination picture; and therefore they never attempt such work. Now, combination pictures can be produced with much ease by any one who enters fully into the spirit of this kind of working without resorting to collodion or floating of one or more films on to another.

The one means a combination negative, which is very rarely attempted; the other means combination printing from one or more negatives on separate supports.

By all means let any one who feels disposed to try his hand at combination printing begin with some *modest* attempt, don't start with a *difficult* subject. There are very many suitable ones to be found in every amateur collection of negatives. Just as an illustration, let me describe a very common example of combination work.

First, procure a negative of some river scene or artificial pond, or such as will permit of a swan being introduced into the picture; then get a good negative of a swan, one that is not too dense. I have even known instances where such a negative was made from a book illustration that had been well worked up. Of course, in producing these, some attention must be given to size of the figures or whatever else it is that is being printed in or combined with the main picture. Proceed, first, to block out on the swan negative the entire surroundings, so that the figure of the swan has no background. This done, proceed and print a copy from such. When printed, take into the dark room, and with the Indian ink block out carefully, after the manner described by me in a previous article, the figure of the swan on the surface of the paper, and set aside to thoroughly dry. When this is accomplished, take the print and place it in contact with the landscape or pond negative, seeing that the black image on the paper occupies a suitable place on the river or pond portion of the landscape negative; then print as usual. Even from a first attempt success is almost sure to follow: or, should there be some slight errors, these will only be from carelessness in blocking out, and are easily remedied.

There is really no end to combination printing, and advanced workers will find such pleasure in undertaking it that they will, before long, be found printing from quite a number of negatives. Like everything else, it is very easy when you once know how to do it. Even with the swan subject referred to, the effect may be heightened by the introduction of some figure into the picture, such as a little girl standing on the brink of the river or pond, holding out her hand in the act of feeding the bird. Interiors are also another fruitful source of good subjects for combination printing—in fact, there is no end to this fascinating branch of photography. The main thing is suitable negatives.

It frequently happens, however, to even the best workers that much chagrin is felt at the bad luck attending many an exposure when some object has moved just when the cap has been removed. I had a case of this sort quite recently, where a fine 15 × 12 negative and picture was spoiled by a cluster of ducks showing a movement on the part of two prominent ones, otherwise all the rest were fine and steady. Now, with many a fastidious worker, this would have been cast aside, but I sat quietly down and turned the two ducks into a good-sized swan, and this is how it was accomplished: Placing the negative on a retouching desk, I got hold of a nursery book in which I knew there were some good pictures of swans to be seen, and, taking one of these as my model, with the aid of a sable brush and oil colour, Prussian blue, I proceeded to draw in, on the film side, a picture of a swan, with its neck gracefully arched, just as it appeared in the

nursery book. This done, I set aside the oil colour to dry. This took some three days to do; but, when printed from, the surprise was complete, the two ducks were converted into a fine, graceful swan, and it would take a very close observer indeed to detect that any dodging had been resorted to. I am safe in saying not one in a hundred looking at this picture could detect, or even suspect, that such a manipulation had been made. Now, there may be an idea on the part of some of my readers that such work as this is only capable of being performed by one who is an expert with the brush or colour work, but such is quite an erroneous idea. There is no difficulty about it when the proper materials are used to accomplish it. It will be observed that I have stated I used Prussian blue. Had I used Indian ink, the result would, in this case, have been not nearly so good. Prussian blue, being a transparent colour, permits of middle tints being introduced as well as denser high lights, according to the thickness of the colour laid on when drawing in the image. Indian ink would have been useless in this case, because no middle tints would have been printed, and just the white flat splash of an image the result; but when transparent colours are used, and placed on in varying depths, we get a corresponding relief in the print that does not appear out of keeping with the rest of the picture.

T. N. Armstrong.

THE STEREOSCOPE.

[London and Provincial Photographic Association.]

In my humble opinion, there is no more beautiful or artistic branch of photography than is produced by the aid of the stereoscope. Some men (and women too, no doubt) see nothing in nature but materiality. That man is no more an artist than he is a musician who, in one of Beethoven's symphonies, hears only noise. Nor do I rank the man who persistently closes one eye when looking through the stereoscope, and tells you he sees two pictures if he uses both his optics, worthy of any consideration. That same man, no doubt, would not see anything whatever on the ground glass of a camera if he were allowed to place his head under the focussing cloth. That the stereoscope is an optical instrument capable of reproducing in apparent relief or solidity all natural objects, by uniting into one image two representations of these objects as seen by each eye separately, is well known. The stereoscope, no doubt, owes its origin to that great inventor, Sir Charles Wheatstone, and the following passage from Mayo's *Outlines of Human Physiology*, p. 288, published 1833, is the, as far as I can find, first clear enunciation of the principle on which it is constructed. "A solid object, being so placed as to be regarded by both eyes, projects a different perspective figure on each retina. Now, if these two perspectives be actually copied on paper and presented one to each eye, so as to fall on corresponding parts, the original solid figure will be apparently reproduced in such a manner that no effort of the imagination can make it appear as a representation of a plain surface." That the two eyes form different images of any objects that are near enough to have dissimilar perspective projection has long been known, and may readily be tested by any one. Thus: I close one eye, and hold a book before the other, so that its back edge obscures the covers; when I open the other eye, I shall be able to see the cover with its printed title. There is no doubt that a certain amount of common sense gives its aid equally to both eyes, to form the union of the two unlike pictures into one clear image. This common sense is especially exerted when the object is placed much nearer to one eye than to the other, so that the sizes as well as the forms of the two retinal pictures are sensibly different. By parallax, on account of the distance betwixt our eyes, we can distinguish, besides the front part, the two sides of a near object, and this gives a visible relievo to such objects, and helps greatly to raise or detach them from the plain in which they lie. Thus, the nose on a face is the more remarkably raised by our seeing both sides of it at once.

Not so very many years ago the stereoscope was to be seen in nearly every drawing-room, and was, no doubt, one of the most popular scientific instruments. Why it has of late years gone out of fashion I cannot understand. Is it that the advent of the amateur taking up photography from nearly every standpoint has had any effect? Certainly very few amateurs take up the stereoscopic side of photography, and I feel certain that a great number of them do not do so from the fact of their believing there are certain *great* difficulties in the art of producing good stereoscopic slides. When the difference between monocular and binocular vision is understood, and the theory that the mind completely fuses the two dissimilar pictures into one is grasped, I see no difficulty that should prevent an artistic and painstaking amateur from producing as good stereoscopic slides as lantern slides; in fact, there is less technical excellence wanted in a stereoscopic slide than in a lantern slide, for the former does not have its faults magnified to so great a degree; and, if the subject is rightly chosen, I am sure the little extra trouble it takes to produce stereoscopic is well recompensed by the beautiful result.

I will not occupy your time by describing the various methods of taking stereoscopic negatives with a single camera and one lens, but will refer you to the very graphic description given by Mr. Traill Taylor in The British Photographic Journal Almanac for 1887, page 53. He is a past-master in the art and science of the stereoscope, and was taking stereoscopic pictures at the last Convention. I must at once say I do not care for the single camera and lens for stereoscopic work. No doubt, for "still-life" pictures and landscapes where there is no life or movement, it is possible to get a good negative; but the variations of light occurring even between a first and second exposure, and the great difficulty of getting both halves of a negative equally exposed, induced me to commence my experience in this branch of photography with a double camera and twin lenses. I will therefore give you my experience, and show you results from the taking of the negative to the making of the transparency.

In the first place, I find a half-plate camera the most useful size for taking the stereoscopic negative, because it has the advantage of being a universal size, and plates of all brands can always be readily obtained. Secondly, the extra height in the picture given on the half of the half-plate allows a certain amount of latitude in the choice of foreground and sky. The ordinary half-plate camera of square form is easily convertible into a double camera by having an expanding partition that divides the camera into two compartments. A cross front of simple form, with the flanges for two lenses, can be used, in which case they should be fixed about two and three-quarter inches apart from centre to centre.

I prefer, however, a dividing front, by which I get a varying distance between the lenses from about two and a quarter to three and three-quarter inches. I have found it absolutely necessary with subjects with near foreground and others with distant foreground to have the means at command for altering the distances between the lenses, and that the fixed separation did not give the best results for all subjects.

The greater the distance of the *nearest* object in the picture, the wider the lenses have to be apart, and *vice versâ*. This can be carried to such extremes that, in taking very distant views of the seashore from the deck of a ship, one picture may be taken by uncapping the lens, and, when the vessel has travelled a hundred yards or so, the other half of the picture may be taken. I do not find, however, that very distant views give an adequate idea of the beauties of the stereoscope. I always endeavour to have an interesting piece of foreground, and, if that is not possible, put a figure in, and the difference in the effect is surprising.

Now, as regards the shutter most suitable. I found some little difficulty in getting quite what I wanted for lenses with a varying distance between their centres, unless I went in for some elaborate arrangement, working directly in from off the plate, and fixed inside the camera. I therefore devised the simple attachment here shown, which consist of two flaps, one of which is *fixed* to a steel spindle, and the other is movable along same, so that, when the desired width between the two lenses is fixed upon, the movable flap is fixed by the small set screw. The two flaps can then be worked simultaneously by the aid of a spiral wire, which prevents any vibration of the camera, and allows of "time" or rapid exposures enough for almost any suitable stereoscopic work, and I have taken many "instantaneous" pictures with it.

As regards lenses, I give my preference to single landscape lenses of from five inches to seven inches focus for all general work, as giving the most brilliant pictures. For architectural work I always carry a pair of R.R. lenses of five and a half inches focus, and I find Voightlander's orthoscopic lenses very fine lenses indeed, and giving grand definition. I would advise gentlemen, when ordering a *pair* of lenses, to see that they get them. The appearance upon the focussing screen of two equally sharp images is no guide as to the exact coincidence of the focus of the two lenses. Do not use iris diaphragms for stereoscopic lenses, for, no matter what the makers may tell you about the great care their individual firm use in marking out the different apertures for the "iris," between these calculations and the engraver's markings on the lens mount, a difference creeps in, and you will find on development, no matter what care you use in setting the "iris," that one half of the stereoscopic picture will develop up much sharper than the other.

I will just make one remark about exposure, which will save a beginner many a pang. Give a generous exposure when taking stereoscopic negatives, or you will have "snowy" pictures. Nothing is more galling than to be asked by one's friend, when showing him

one of your best slides, if it was snowing when you took the picture; although, by the leaves on the trees, he ought to have been able to see it was midsummer when the picture was taken. In a monocular photograph, a bit of white may be allowed upon the trees, and roofs, and pavement; but with a stereoscopic slide, otherwise specially good, the snowy appearance will entirely ruin its artistic beauty. Give, therefore, a generous exposure, develop up carefully with weak solution, and aim at a somewhat thin negative with full detail.

NEW TONING BATH FOR GELATINO-CHLORIDE PAPER.

In connexion with his new toning bath for gelatino-chloride paper which he introduced to the meeting of the London and Provincial Photographic Association on August 11, Mr. W. D. Welford has favoured us with the following further particulars:—

Those who have worked years ago with prints from wet-plate negatives will remember the simple bicarbonate of soda toning bath, and the somewhat washy nature of the results which made it useful for very brilliant prints, but not suitable for others. A slight bleaching action takes place, which was in turn an advantage and a nuisance. Remembering this, I tried the old formulas upon the new Eastman paper, but found no gain in any way until the strength of the bath was increased. I claim nothing for the use of bicarbonate of soda in the toning, but I do claim to have introduced a bath for chloride prints that possesses several valuable points which are as follows:—

1. The bath is made at time of use.
2. It is simplicity itself.
3. It tones the prints quicker than any other.
4. The unevenness of toning, which is usually the bugbear of chloride prints, absolutely annihilated.
5. It gives a pleasing grey black tone, resembling platinotype.
6. Over-toning impossible.

The prints are completely toned in one and a half to two minutes. The tray need not be moved at all, and if six prints are immersed it takes all the operator's time to keep them going. As fast as he can get them out of the tray he can insert a fresh print. Uneven or partial toning is really one of the strongest points, because, as a matter of fact, unless the prints show some trace of this, I get suspicious. I can completely tone half a print first, then the other half, and no dividing line is apparent. A dozen air bubbles or streaks can be left on the print, with the result of a dozen bright and red spots upon the otherwise finished print; and yet, if these be covered over and the toning continued, there is no trace whatever when finished.

The fact is, and here lies the merit of the whole thing, a definite tone being obtained, no amount of immersion in the solution (within reason, of course) will alter that tone, so that, in the case of red spots, they merely *catch up* to the other part. This is very apparent if a print be toned in, say, four sections, as it is impossible to show the four degrees, the second one toning to the level of the first before the third can get a start. As regards over-toning, I have left the prints an hour without any difference between them and those taken out in two minutes.

I claim that this bath makes the chloride paper easier and quicker to finish than any other silver paper, and it will even bear a favourable comparison with any method of printing and finishing at present in use.

The bath is as follows:—

Gold chloride	4 grains.
Bicarbonate soda	1½ drachms.
Water	6 ounces.

It will be noticed that, compared with the usual baths, it is exceedingly strong. I claim that, in conjunction with the use of bicarbonate of soda, as the feature of it. I see, in an American paper, that bicarbonate of soda is recommended, and in England borax is mentioned. But neither of these use such a strong bath. As a point of comparison, let me place the two baths together.

Usual Carbonate Bath.

Gold	4 grains.
Bicarbonate of soda	16 „
Water	32 ounces.

My Bath.

Gold	4 grains.
Bicarbonate of soda	90 „
Water	6 ounces.

It is evident, therefore, that I have done more than merely recommend the usual and old bicarbonate bath.

The prints need washing before toning, a slight rinse afterwards, and final fixing in a weak solution of hypo (say, one to six) for about ten minutes. Over-printing is necessary to allow for the bleaching and reducing action, but the actual toning of the print does not change at any period of the fixing. The print must be judged by looking through, to a strong light. As soon as the last trace of red or brown has gone it is finished.

For those who prefer a warmer tone and slower action, it is only necessary to double the quantity of water and rock the tray.

My own opinion—doubtless an egotistical one—is that this bath will do much to popularise the use of gelatino-chloride papers; because, although the manufacturers declare that a child can tone their paper, and that if a photographer cannot he is a muff, yet I am certain that many *have* found difficulties in toning, which all those who have worked with the above bath declare to have completely vanished.

HARMONISING HARSH NEGATIVES.*

A method of intensifying the shadow detail without increasing the density of the high lights to a greater extent by bleaching the surface of the negative with mercury, stopping the action before the whole thickness of the high lights is affected, washing well and blackening with any of the usual agents, was demonstrated before us by Mr. Roland Whiting, and will be found useful.

A similar method has been repeatedly advocated by Mr. Chapman Jones, the agent being the uranium intensifier.

As this intensifier performs its work at one operation, it is claimed that the action can be stopped as soon as the shadow detail has been sufficiently strengthened, and before the lights have been intensified right through. I tried this on several occasions about a year ago, but was never successful in stopping the action at the right moment, the red colour of the intensified parts differing so much from the normal appearance of the negative makes the process a little confusing, and it is not easy to estimate the value of the added strength. At the same time I accidentally found out that ammonia would entirely remove the red deposit, and hoped that by intensifying the negative fully, and afterwards painting out the red stains from the lights with ammonia, I might obtain the desired results. I found, however, that it was difficult to control the action of the ammonia when dealing with fine lines, sprays of leaves, &c., and gave up the use of it. I see that Mr. J. Hodges has an article in the number of the *Quarterly* previously referred to in which he advocates this method. He shows prints from a negative before and after treatment to which I call your attention.

You will see from these that Mr. Hodges works his method with complete success. His acknowledged skill in all branches of photographic work entitles his method to consideration and trial by those who have time to acquire the manual dexterity necessary to work it successfully. I think the method will be found most useful when broad masses of light half-tone, merging into the shadows, are to be treated. It must be remembered that both Mr. Chapman Jones's and Mr. Roland Whiting's method of intensifying the shadow detail also strengthen the high lights. Neither of these methods nor that of Mr. Hodges will be found satisfactory when the negative is already too dense in the high lights. Even if we were by any of these methods able to strengthen the shadow detail to such an extent that the light half-tone would print out before the shadows were blocked up, the negative would be so dense that printing would be enormously prolonged, to the deterioration of the printing paper.

What we require in such cases is that the reducer should act upon the high lights at the back of the plate, and leave the shadow detail unaltered. Should the latter be then too thin, we can intensify the whole negative without the brilliancy becoming too pronounced.

* Continued from page 540.

I desire to call your attention to a method of working which will yield such a result.

Shortly after giving up the use of the uranium intensifier in connexion with hard negatives, I observed this formula, and instructions in the editorial column of the *Amateur Photographer* (October 2, 1891):—

"The only way to reduce the dense portions of a very hard negative without reducing the shadows is to wash free from hypo, and then immerse in:—

Hydrochloric acid (pure)	9 drops,
Bichromate of potash	30 grains,
Alum	10 ,,
Water	1 ounce,

till thoroughly bleached, then wash well for an hour or more, and redevelop with a weak and well-restrained ferrous oxalate developer, and stop the development as soon as the shadows have developed, and before the high lights are reduced right through, then refix."

This appeared to promise well, and I tried it. For redevelopment I used the ferrous oxalate I had prepared for alpha paper, as it met the requirements if weak and well restrained.

Repeated trials gave me nothing more than a ghost image after prolonged development, when viewed after fixation.

On making inquiries, I was told by a worker whom I considered an authority on the subject that the chloride of silver image produced by rehalogenisation was so insensitive that a prolonged exposure to daylight would be necessary. This necessitated previous drying to prevent irregular action, and of course added to the trouble of the process. I found after exposure to daylight that the image developed readily enough; but a new difficulty arose, it was impossible to tell when the action of the light had penetrated to a sufficient depth into the film, and if it went too far the hypo was unable to dissolve out the orange-coloured light product, with the result that, while the shadow detail was by development of a black tone, the undeveloped high lights, if solarisation had taken place, were of a strong non-actinic orange tint, and for printing purposes just as strong as at first. The process seemed too uncertain to be of much practical use, and I abandoned it.

Some time after this Mr. Chapman Jones referred to a similar process, in which chloride of iron was the rehalogenising agent, the result, of course, being again chloride of silver.

I felt that such a process, if it could be worked with certainty, would be most useful, and it occurred to me that, if bromide of silver could be substituted for chloride of silver as the haloid salt, it would be much more sensitive to artificial light, and the whole operation could be carried out in the evening. I was acquainted with and had used Captain Abney's formula for resensitising light-struck but undeveloped plates, viz., bichromate of potassium, and bromide of potassium. This is inert upon the metallic silver image produced by development; but, knowing the power of bichromate of potassium as an oxidiser to assist the acids in combining with the metals, I believed that the addition of nitric acid would accomplish my purpose. Clearly, it was necessary that the bromide of potassium should be present from the first to change the nitrate of silver as it was formed into an insoluble salt, or the image would be washed away. A few trials led me to adopt the following formula and method of working:—

Bichromate of potassium	10 grains.
Bromide of potassium	5 ,,
Water	1 ounce.

Bath the plate, and allow the solution to permeate the film. Pour the solution off, and add to it five drops of nitric acid. Again flood the plate, and the image will be converted into bromide of silver. Allow the action to proceed through the film. Bath in three changes of alum to remove the bichromate and harden the film, and wash thoroughly in water. As the operations are carried out in white light, such as that of gas or a lamp, the plate is amply exposed by the time the washing is complete.

For development I abandoned iron as being troublesome to make up when a single negative had to be treated and had to be followed by a clearing bath before fixation. I tried hydroquinone as being something of the same character, but found that it frilled the film off the plate whether the caustic alkalies or the carbonates were used. The previous long soaking would account for this. I then tried pyro, and found it quite suitable. Any preservative may be used (my favourite is nitric acid), but, as there is nothing on the plate but the image to be affected by the developer there is no necessity to use a bromide. A small trace may be useful to control development, but, if any bichromate of potassium remains in the film, it will unite with the bromide, and convert the image back into bromide of silver as fast as it is developed. The formula I generally use is:—

Pyro	2 grains.
Ammonia	2 minims.
Bromide of potassium (if used at all)	¼ grain.

As the shadow detail lies upon the surface, it will first be developed, the half-tone will follow, and the high lights will remain white when viewed from the back of the plate for some time. As the surface of the film will veil over as soon as the developer begins to act, the progress must be judged entirely from the back of the plate. The only judgment required in the process is in stopping the development at the right time. If stopped too soon, the negative will be flat; if carried too far, the negative will still be hard. It will be well to have ready for reference a print from the negative in which the shadows have been printed to their proper depth. When the lightest half-tone which shows in the print is nearly, but not quite, blackened through by the developer on viewing the plate from the back, the action should be stopped, the plate washed, and transferred to the hypo, which will speedily dissolve out the undeveloped silver in the high lights, leaving the negative much thinner in the high lights than it originally was. A little practice with waste negatives will give the required power of judgment.

A negative which is hard from under-exposure, and one which has been fully exposed but is hard from over-development, will not present the same appearance during redevelopment after rehalogenisation. If the former be redeveloped right through, the high lights will appear black at the back of the plate. The high lights in the fully exposed negative will never appear black however far the redevelopment may be pushed, and, as the layers of white-coloured silver present in this case will not be dissolved out by the hypo, an allowance for this must be made in redevelopment, or the negative will still be too dense. There is no theoretical objection to the negative being again treated by the process to obtain the required reduction, but in practice there is an additional risk of stains appearing the second time. It is better to err on the side of under-development and intensify if necessary.

I found the method so successful that I should probably never have tried the chloride method again, and would have supposed it to be too uncertain for practical work; when, however, I was asked to make this process the subject of a paper, it became necessary to investigate the matter a little more closely lest I should lead some one astray. By the experience I had acquired I suspected the "weak and well-restrained ferrous-oxalate developer" to have been the cause of my early troubles. On rehalogenising a negative by the chloride process I found that the exposure to lamp light was quite sufficient if developed with pyro, and the image all that was required. I would, however, in future omit the alum from the solution and reduce the bichromate of potassium to 10 or 12 grains per ounce, and the hydrochloric acid to 5 drops. We have, then, two methods to work with, and, though I think the bromide is a little more under control, this probably arises from my having had more experience with it. J. McINTOSH.

(*To be concluded.*)

Our Editorial Table.

SUNSHINE.

By AMY JOHNSON, LL.A. London: Macmillan & Co.

WHAT Mrs. Barbauld, in her *Evenings at Home*, and the Author of *Sandford and Merton*, together with like popular educational writers did for children of former times, Miss Amy Johnson is endeavouring to do in her book *Sunshine*, in which science-teaching is brought up to date. It will be readily admitted that the imparting of scientific knowledge, more especially the science of the sunbeam, to children more or less young, is a task of very considerable difficulty, and one which comparatively few would have the courage to undertake. Yet here we find an evidently talented and well-read lady filling a volume of over 500 pages with discourses to young folks—a real or imaginary class—on such topics as the nature of sunshine, reflection, refraction, the formation of images by pinholes and lenses, the camera and the stereoscope, shadow pantomimes, and even sundials. We can strongly commend Miss Johnson's book as one replete with useful information, given in a taking style. But we might, without seeking to detract from the work, hint to our authoress that, while she is quite correct in surmising that the photographers' lenses (in stereoscopic photography) must be exactly alike, she is wrong in saying that "as it is

impossible to make two lenses alike, even out of the same glass, one lens is cut exactly in two, and the halves are placed at a distance of two and a half inches, which is about the distance between our eyes." This, we are aware, was taught in some measure by Sir David Brewster, but it does not apply to binocular photographic practice of the present day.

The work is profusely illustrated, and is well printed. Price 6*s*.

Ilford Printing-out Paper.

It is scarcely necessary we should again say that this paper is not surfaced with albumen, but with gelatine. Paper of this sort has much to commend it, not the least being the getting rid of sulphur, which is recognised as a powerful element in albumen. The Ilford printing-out paper has a beautiful surface, and prints rapidly to a fine purple tone. In our trials we employed a toning and fixing bath in one, and obtained every kind of tone we desired, from a red, passing through purple, on to one of platinum blackness. No special over-printing was required to obtain even this last effect, as by the system of toning and fixing we adopted there was but little reduction of the image.

Photographic Convention Pictures.

(Snap-shots with Fallowfield's Minit Hand Camera.)

Mr. F. W. Hindley is an expert snap-shottist, if we judge by a series of pictures of this class taken by him during the recent convention at Edinburgh. Here we have a group waiting to enter a railway carriage, and there we have Miss Barnes in the act of uncapping her lens, with a winning smile on her countenance, doubtless induced by pleasant conversation with some of those in her proximity. Other views represent scenes in the fishing village of Newhaven, at Abbotsford, Melrose, and other places in Scotland. All are excellent.

Mr. H. M. Hastings sends us a characteristic group of gentlemen, more or less well known in the photographic world, taken during one of the Convention outings at Cramond. As Mr. Hastings is a master in hand-camera work, it is scarcely necessary for us to say that this one is technically perfect.

A Convention Group.

By John Stuart, Glasgow.

This beautiful group was taken by a Zeiss lens, of 7¾-inch focus, working at *f*-12·5. The size is whole-plate; the definition is excellent. It is well printed on gelatino-chloride paper, of which process Mr. Stuart is a highly successful exponent.

PHOTOGRAPHY AND ARCHÆOLOGY.

The Report of the Committee of the British Association, consisting of Mr. E. Seward (Secretary), the Marquis of Bute, Messrs. G. T. Clark, R. W. Atkinson, Franklen G. Evans, C. Tanfield Vachell, James Bell, T. H. Thomas, and Dr. J. G. Garson, appointed to report on the Prehistoric and Ancient Remains of Glamorganshire, stated that the Cardiff Amateur Photographic Society, by means of prizes offered to their members, have produced some hundreds of valuable original photographs of prehistoric and ancient objects in the county, most of such objects within the county having thereby been illustrated. This collection, which is believed to be the most extensive yet formed in any district, is stored at the Cardiff Free Library. The Corporation have given good aid to the work by important grants to the prize fund.

PATENTS COMPLETED.

An Improved Photographic Developing Apparatus.

No. 6013. Arthur Brin, 1, Charlton-villas, Park-road, Twickenham.—*July* 30, 1892.

My invention relates to a photographic developing box, whereby negatives or positives may be developed in the open without recourse to the ordinary dark room or tent.

It consists of a narrow, upright, liquid-tight box, provided with non-actinic transparent sides to enable the development to be watched, and combined with means whereby the developing and washing liquids may be quickly introduced and withdrawn in succession, each liquid being for this purpose contained in a separate elastic pneumatic bulb or pump barrel, connected by a flexible or other tube with the lower part of the box, a clip, or other means of interrupting the flow through the pipe being provided to enable the solution to be held in reserve or kept in action as long as may be required.

The inlet of the box at which the negative or positive is introduced is surmounted by a chamber, with which the dark back of the camera is adapted to make a light-tight joint, the interior of the chamber being of such shape as to guide the negative or positive through the inlet of the developing box, in whatever position it be delivered from the dark slide.

A lifter of clear transparent celluloid is provided, in which the negative or positive is held during development and consequent operations, and by which it may be readily withdrawn when completed.

The dark back is provided with a door or slide, opening into the said chamber, at which the negative or positive may be dropped or slid on to the incline guides leading to the developing box, and means are provided for ensuring correct register of the said door or slide with the box-inlet.

By the employment of the pneumatic bulbs, the liquids are not run to waste, but are automatically withdrawn from the box and returned to their proper reservoirs for re-use as often as may be required, thus avoiding the necessity of replenishing after each development, and of carrying a supply for that purpose.

A New or Improved Apparatus for Obtaining Bird's-eye Photographic Views.

(A communication from Ludwig Rohrmann, Krauschwitz, Germany.)

No. 12,669. Edmund Edwards, 35, Southampton-buildings, Chancery-lane, Middlesex.—*July* 30, 1892.

The present invention is applicable more especially to military operations by taking photographic bird's-eye views of fortifications, or other positions occupied by an enemy, from a distant position where they are not visible.

It may be also applied to other operations not of a military nature, such as taking bird's-eye views of buildings, estates, or land.

The improved arrangement consists of a parachute, having hung to it below an instantaneous photographic apparatus, the parachute in its closed condition being contained in a space prepared for it in a suitable projectile. The projectile is fired high in the air, in the direction of the object to be photographed, a charge of explosive being then ignited, and the parachute apparatus being thereby set free from the projectile. The parachute then operates automatically, falling by itself, the photographic apparatus hanging perpendicularly below it, and by a suitable arrangement taking one or more instantaneous photographs of the positions on the earth below, the parachute being then brought back to the point from which it was projected by a line, one end of which is attached to it, the other being retained at the starting point.

In one method of putting the invention in operation, a rocket is used, a space in the front end or cap of which contains the parachute apparatus. This rocket is ignited and fired from a stand of the usual kind, or any other suitable support. During the flight of the rocket, the ignited composition in the latter reaches a fuse, and fires an explosive charge in the front end. This explosion bursts open the rocket-cap, which is made of earthenware or sheet iron, the parachute apparatus being prevented from injury by the fire by means of a plate or pad of asbestos. In order that the rocket-cap may free the parachute apparatus with certainty, it may be made with grooves or notches, so as to weaken the material, and allow a small explosion to bust open the cap. Or it may be so arranged that, if sheet iron is used, the latter is unrolled or flattened out. The parachute apparatus is perfectly independent after this, as already explained.

The attaching cord is fastened where the apparatus is attached to the parachute, and is led through a hole in the rocket-cap, or beneath the latter, to a winding drum at the firing point, which may be worked by a small steam-engine or by hand. Insulated electrical wires may be carried by, or form part of, the connecting cable, and in this case the mechanism of the photographic apparatus may be worked by their means from the starting point. About three metres of the line, where it adjoins the parachute, are made of wire to prevent the risk of its being burned.

In order that the improved apparatus described for taking bird's-eye views may be projected to greater distances, the parachute may be fired from an ordinary gun, instead of a rocket being used. In this case the folded parachute and the photographic apparatus are contained in a cylindrical shell having a pointed end in front, into which a time-fuse is screwed, which is fired in the usual way by the explosion, and exactly at the determined time

ignites the bursting charge, so that the parachute and photographing apparatus are set free.

In this case also the parachute is separated from the bursting charge by a pad of asbestos, so that it is prevented from being injured by the fire.

The gun used is a muzzle-loading mortar of sufficient length, which is carried by, and adjustable in, a suitable frame. In the barrel parallel air grooves are made, which are not rifled as in ordinary guns, as the revolution of the shell would break the connecting line, which is laid in one of the longitudinal grooves in the barrel.

Between the shell and the cartridge, which latter is fired through a touch-hole, an arched disc or plate of iron is inserted to prevent the possible breaking of the shell and the parachute apparatus when the gun is fired. The plate is shot out of the gun, and then falls to the ground. The parachute, which is of the ordinary well-known construction, opens out as soon as it is freed, and the photographic apparatus hangs perpendicularly below it. By a suitable arrangement the parachute is prevented from collapsing.

The photographic apparatus is of the kind used for taking instantaneous pictures. With it is combined spring clockwork, which is wound up before the gun is fired, and must be arranged according to the calculated time of flight. It then comes into operation and effects the instantaneous exposure of a plate, when is then moved sideways from its position, leaving another plate in position for a fresh exposure, and so on. In this way, by a single shot, six to eight exposures may be made.

It is evident that, by means of a series of exposures, a complete circle of views round the firing point may be obtained.

For this purpose, as many shots as are necessary are fired in succession from the firing point as a centre, so that, when the several pictures are put together, a complete map of the country may be obtained.

The following is one of the forms of photographic apparatus which may be used with advantage :—The apparatus hangs below the parachute, with its lens pointed down, and consists of an ordinary chamber or camera, containing the plates for exposure, and another adjoining chamber, into which they are removed after exposure. The plates, each fitted in a wooden slide, are arranged one above the other in the first chamber. Above the pile of plates is arranged a pressure plate, which presses the plates downwards by means of springs. The lower edges of each plate-slide are fitted with two parallel toothed racks, and the racks upon the lowest slide gear with corresponding toothed wheels, driven by the clockwork contained in a chamber at the lower part of the apparatus. This clockwork also serves to open and close the lens in order to expose the plates and obtain the pictures. When this has been done, the lowest slide is removed by the toothed racks and wheels, together with the exposed plate which it contains, into the adjoining chamber. The bevelled edge of the next slide, after the plate in it has been exposed, is passed under the edge of the first one, which it lifts as it is removed from the first chamber into the second, and this operation is repeated for as many plates as are contained in the apparatus. A space for single plates may be left above the second chamber.

In the construction of the parachute, the ribs of the latter are preferably jointed to a central cap, and to these ribs are jointed radial stays, as in ordinary umbrellas. The inner ends of these stays are jointed to a central plate, which is connected to the upper cap by a spring, which draws them together, so that the parachute is at once automatically opened as soon as it is set free from the shell, as already described.

The photographic apparatus is hung by lines from the ribs of the parachute, the lower ends of these lines being connected to a universal joint, from which the photographic apparatus is suspended, so that the latter is not affected by the oscillations of the parachute. To this universal joint the connecting line to the firing point is also attached.

Improvements in Photographic Cameras.

No. 16,708. Adolf Hesekiel, 32, Landsbergerstrasse, Berlin, N.O. 18, Germany.—*July* 30, 1892.

The object of the invention is, firstly, to economise space in the storage of the sensitive plates within the camera, and it consists in arranging side to side, or one above the other, two chambers, each intended to be filled with the holders, in which the sensitive plates are separately placed, so that as each plate is exposed it may be moved from the one chamber to the other, the remaining plates in each chamber being shifted, the one set forward, the other backward, to provide space for the plate so moved, and to replace the vacant space at the back of the first chamber with a plate from the second chamber. This is effected by two slides joined together by a bridge, so that they must be moved simultaneously; the one slide is adapted to catch under the recently exposed plate, so that, when the slides are lifted or drawn out, this plate is conveyed to the other chamber and left there; the other slide is adapted to catch over the plate at the other end of the said chamber, so that, when the slides are moved in again, this plate is carried from the second to the first chamber. Springs press the plates along in the chambers.

The number of plates moved—that is, of exposures made—is indicated by the following contrivance :—A numbered disc is pivoted so that a number on the circumference may show before a small window in the back of the camera. This disc carries an interiorly toothed wheel with inclined teeth. On one of the slides is a pin, so that, when the slide is moved into its outermost position, this pin comes in contact with the side of one of the teeth, and moves this tooth with the wheel and disc; on the return of the slide the same pin strikes on the opposite side of the wheel and moves the wheel by arriving against the inclined face of a tooth on this side thus with both movements, changing the position of the disc sufficiently to bring the next succeeding number before the window.

A further improvement relates to the focussing and finding of the view when the plates remain in position in the camera. The rays from the lens are deflected by an inclined mirror on to a ground glass at right angles to the sensitive plate in the known manner; but this ground-glass plate is enclosed in a space provided with a door, so that darkness prevailing in this space even with the door open the view is much more clearly seen than when the ground glass is in the outside of the camera, no focussing cloth being required. As the ground glass is a part of the wall of the actual camera or photographing chamber itself, the mirror is hinged so that it may be closed over the ground glass and thus prevent access of light through the latter; when the mirror is in position for focussing or view-finding, it lies upon a screen preventing passage of light to the plate hidden behind the mirror, the latter covering the hole in the screen through which the light would otherwise pass from the lens to the plate.

It is preferable that the door aforesaid should only be opened when the mirror is actually in position for focussing. This is effected by providing a spring for closing the door and a rod for thrusting the latter open, this rod being moved by a rotary arm or tappet on a spindle turned by the operator. The spindle carries a second arm with a pin engaging in a slot in the side of the frame of the mirror, so that by turning the spindle the mirror may be moved into or out of position for focussing; the tappet does not strike the rod until after the mirror is in position for focussing, and it leaves the rod before the mirror is moved on the reverse motion of the spindle.

Improvements in or relating to Photographic Cameras.

No. 20,007. Xavier Gustave Edouard de Faucompré, 33, Boulevard Haussmann, Paris, France.—*July* 30, 1892.

This invention relates to that class of photographic cameras in which the sensitive film is formed by or upon a continuous web carried by rollers and adapted for taking a number of negatives in succession, and the improvements which are applied to the mechanism for actuating the rollers carrying the web are designed mainly to ensure by automatic action of the various parts that it may not be possible for the operator to make any mistake in bringing a fresh portion of the web into proper position after taking each negative.

The apparatus is enclosed in a box, which only presents externally a push button, an eyepiece, two orifices to receive keys, whereby the rollers are turned, and a movable slide or screen. Between the sides of a wooden frame are placed a number of rollers; one of them, the supply roller, carries the web of sensitive material unacted on, and another serves as the roller upon which the web is wound as the negatives are taken upon the sensitive film, which is stretched vertically between guide rollers. The supply and receiving rollers are alike, and are interchangeable, and they may be removed and replaced. These rollers are made of wood or other material, having disc ends furnished with metal caps. The caps are slotted to receive pins, by which they are connected to gearing discs, and a screw serves to secure each cap to the end of the roller. A slot is provided, into which the end of the web is inserted, and thereby secured on the roller. The receiving roller is turned in one direction to wind on the web by a key fitted to the end of its spindle, a pawl and ratchet serving to prevent its rotation in the opposite direction. A disc, having a notch in it with which engages a catch upon a lever, serves to stop the movement of the rollers and other parts of the apparatus when a length of the web has been drawn off equal to the length of negative exposed. To prevent the catch engaging the notch in the disc when the apparatus is prepared for action, a lever is provided, having at its end a catch arranged to cause the disengagement of the first lever at a given moment. The lever first referred to has a notch wherewith engages a hook forming the opposite end of the second lever.

A counter is placed at the centre of the apparatus, and serves to register the number of negatives exposed and drawn on to the receiving roller. This number, which is indicated on a dial, is seen through a glazed opening in the cover of the box.

A ratchet for actuating the counter is operated by a rod and pawl. The several parts are operated by a push button or knob.

The supply roller is kept stationary by a jointed catch engaging a ratchet on it, and is operated by a rod or lever. A brake is fitted to bear on the supply roller and control the speed at which the web is unwound, regulation of the pressure of the brake being effected by a screw.

At the end of the lever first referred to is fixed a needle, which pricks the sensitive web to mark off the negative after each exposure.

The operation of the apparatus is as follows :—In order to wind on to the roller that portion of the sensitive web that has been exposed, the operator presses the knob, whereupon the lever turning on its pivot is moved a short distance, and is held by a hook. The operator may then turn the receiving roller, and thus bring into position for exposure a fresh portion of the web equal to the length of negative exposed. During this operation the lever, acted on by the knob, is automatically disengaged from the hook by the oscillation of the second lever, which is acted on at its end by a wyper. A projecting catch enters a notch in a disc, and stops the operator when the supply roller is stopped. By this time the web has traversed the entire length of the frame. The levers have then returned to their normal positions, and the operator has only to press the knob a second time and turn the roller to obtain a second negative, and so on until the supply of sensitive web on the roller gives out. The supply roller may then be replaced by one containing a fresh supply of the sensitive web, and the filled roller replaced by the empty one.

The construction of the interchangeable rollers permits of the replacing of the supply roller without having recourse to the use of a dark room. At the end of each web length is fitted a black or darkened strip, which, when the supply roller is put in place, covers the sensitive web and prevents the action of light upon it, and a like strip at the other end serves to cover the exposed web.

To prevent access of light at the edges of the sensitive web a narrow darkened border is formed on each side.

[As some of the items in the special claims attached to the complete specification were long previously published, a disclaimer will be necessary in order that this patent may be maintained.—Ed.]

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AUGUST 23,—Technical Meeting.—Mr. J. Traill Taylor in the chair.

Samples of amidol (the new developer) and of Richards' patent corners for securing photographs to the corners of albums were placed on the table.

PORTRAITURE OTHER THAN IN THE STUDIO.

In introducing this subject, Mr. J. NESBIT observed that, in taking portraits out of doors, the art of the retoucher was necessary. He had found that in portrait work done with a rapid symmetrical lens he got much detail and very sharp definition. He did not like to take such photographs unless the definition was clear. He took photographs as he saw them with his eyes, and not in the blurry manner now prevalent. He thought it a mistake in photographs of whole-plate size or less to have them at all blurred. He could not see the value of blurriness. Mr. J. Nesbit then passed round a series of outdoor portraits of the Chairman, Mr. C. Ray Woods, Mr. Cowan, and other gentlemen, drawing special attention to two portraits of Mr. E. Dunmore, one untouched, the other retouched. In reference to the latter, which Mr. E. Clifton had kindly printed in platinum for him at very short notice, Mr. Nesbit observed that the retouching had been skilfully executed by Mr. Redmond Barrett in a very short time. Mr. Barrett had made his name not only as a writer but as a demonstrator and retoucher. In the untouched portrait of Mr. Dunmore the corrugations were painful to see, whereas the retouched portrait was a very pleasing and successful one. Outdoor portraiture necessitated more retouching than studio portraiture, especially if such lenses as Ross's rapid symmetrical were used—those gave such wonderful definition. He had opened out such a lens so as to make it practically a portrait lens. In reply to the Chairman, he said the aperture would then be about *f*-6. The photographs he exhibited were taken in the angle of the walls of the back part of his house.

Mr. J. WEIR BROWN had recently attempted indoor portraiture, and exhibited some specimens taken in an ordinary room. The sitter was placed near a double window, half of which was partly stopped out by the blind, the light streaming through the other window at an angle of forty-five degrees, a white fabric being used on the shadow side as a reflector. In reply to the Chairman, he said he avoided the light spot in the eye by controlling the angle of light.

Mr. CHAPMAN JONES remarked that he never found the secondary light spot appear.

Mr. W. E. DEBENHAM described the most favourable conditions for outdoor portraiture, the sitter being placed with his back to a house, with a wall at the side. Such an arrangement gave results which might be taken for studio portraits. He had often taken portraits that way on account of the greater rapidity obtained. For portraiture in rooms, he placed the sitter nearly level with the window, or a little behind it, with a reflector on the shadow side, brought nearly forward to the camera, but not behind it. If behind the sitter, the outline of the head would be lost. For Rembrandt effects, he would place the reflector further back. Mr. Debenham exhibited a number of indoor portraits, chiefly of invalids, taken in the manner he had described.

Mr. T. SAMUELS asked whether the reflector should be inclined or perpendicular.

Mr. DEBENHAM replied that he generally placed it perpendicular. Using a plain white material, the angle was immaterial.

The CHAIRMAN described Solomon's system of indoor portraiture in a tent, with [illegible] as the illuminant, and said that in trying it he obtained flat results. He described the system by the aid of the blackboard. A method which gave admirable results was to place the sitter in front of a window, and photograph him from the outside. The Chairman concluded by referring to the system of employing a mirror to reflect the image of the sitter, and photographing that, describing the effects of lighting obtainable as very beautiful, and recommending it as a good system of indoor portraiture.

Mr. T. R. DALLMEYER said that Mr. Debenham, in stating that the alteration of the angle of a dead surface produced no alteration in the light reflected, was wrong. The same law with regard to the reflections from polished surfaces was followed, the difference being one of degree. Mr. Debenham said that it made no difference, but he (Mr. Dallmeyer) asserted that it did, and that was the point.

After further discussion on this point the meeting adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 18,—Mr. F. A. Bridge in the chair.

Mr. Percy E. Marshall, of 36, Victoria-street, S.W., was elected a member of the Association.

Mr. Beckett passed round a negative, one half of which was badly fogged, the other half quite clear; the result was considered remarkable, and he promised to bring the exact formula to the next meeting.

A question was asked as to whether a reply to a question in one of the photographic journals was correct. The reply was to the effect that eikonogen with carbonate of soda *would* successfully develop a wet-plate negative.

Mr. T. BOLAS said the reply was quite wrong; such a developer used for wet plates would precipitate the silver right away.

Mr. W. P. DANDO then opened the discussion of the evening on *Stereoscopic Photography*. He read a paper [see page 552], and passed round many prints and transparencies.

Messrs. G. W. Atkins and T. E. Freshwater also passed round stereoscopes and prints.

In the discussion which followed, Mr. DANDO said he could not agree with Mr. Chadwick that stereoscopic pictures should be no higher than the regulation size.

The CHAIRMAN, with regard to the distance between the lenses, stated that Mr. Nesbit, a great authority on such questions, had advised two and three-quarter inches between the lenses as a good average distance.

Mr. BIRT ACRES thought that the separation of the lenses to exaggeration had been the means of bringing stereoscopic photography into disrepute. When taking near pictures, such as flowers, &c., he thought that the lenses should be brought closer together, and he thought also that the lenses used should match, in the distance between, the lenses used in the stereoscope. He showed a stereoscope of his own invention, which, however, he had not quite perfected.

Mr. W. E. DEBENHAM referred to an instrument he had "re-invented"—the tele-stereoscope. He thought there would be great advantage in examining distance stereoscopically, and also for use in military operations. He thought also that the distance *between* the two eyepieces could be altered at will.

North Middlesex Photographic Society.—August 22. In the absence of Mr. Wall, Mr. Walker took the chair.—Forty-five members and friends were present. The Chairman introduced Mr. DEBENHAM, who addressed the Society upon the subject of *Transparencies by the Carbon Process*. He recommended that the tissue should be bought unsensitised, and sensitised as required by this formula: Bichromate of potassium, 1 ounce; ammonia, 1 drachm; water, 30 ounces. Or, if the tissue had to be kept for some time, it would be well to increase the water to 40 ounces. About three minutes' soaking would be sufficient. It should then be squeegeed on to a plate of glass (into the pores of which talc had been thoroughly rubbed), dried, and stored for use. It would strip with a bright surface, which would lie in close contact with the negative. He recommended, as an actinometer, that a negative of medium density should be taken, and, while the carbon print was being made, that a print on silver paper should be made through a small opening in a mask. He emphasised the necessity of a safe edge to the carbon print, and that the cut-out mask for that purpose should be placed outside the negative instead of between the negative and the tissue. By this means the safe edge would be vignetted off instead of showing a hard line, and there would be less risk of frilling in developing the print. It was necessary that the print, when placed in the cold water prior to development, should be squeegeed on to a sheet of glass before it had absorbed all the water it was capable of holding, otherwise it would be unable to take up the film of water on the glass, and close and permanent contact would not be made. Mr. Debenham illustrated his lecture by diagrams on the blackboard and by passing round transparencies, &c., in various stages of progress. He then proceeded to develop several prints, calling attention to the precautions necessary to secure good results. Many questions were asked and answered, and a vote of thanks was moved by Mr. MARCHANT, who said the Society was indebted to Mr. Debenham, and to the Affiliation Committee of the Photographic Society of Great Britain, who had made the arrangements for the interesting and practical demonstration just delivered. Mr. COX seconded the motion, which was carried with acclamation. The usual competition of views taken at field-days was held, the vote of merit being secured by Mr. A. G. Hewson, for West Hampstead. A large number of plates, kindly sent by the Paget Company, were distributed, each member present receiving a packet. Attention was called to the Hill Norris dry-collodion plate, particulars of which had been received. The next meeting will be held on September 12, when Mr. H. Smith will take the chair, and Mr. Beadle will demonstrate the making of lantern slides on various plates. Visitors welcome.

Hackney Photographic Society.—August 16, Mr. Beckett in the chair.—Messrs. Salmon, Dando, and Nunn showed prints on the Ilford P.O.P., samples of which had been sent. In every case satisfactory results had been obtained, Mr. DANDO stating that the bath he had used for toning was: Hypo, 1 ounce; alum, 6 drachms; water, 8 ounces. Let stand until properly dissolved, shake up, then add, in small quantities at a time, a solution of three drachms of carbonate of soda (crystals) in one ounce of water. Filter, let stand for a day, then add 1 grain of chloride of gold and 2 grains of acetate of lead (previously dissolved in 1 ounce of water). Printing must be carried on to a rather deep colour. Mr. ROBERTS said he had obtained a brick-red colour in print by printing in sunlight. The CHAIRMAN said that Mr. Welford had given a good formula for toning bath, consisting of 6 ounces of water, 4 grains of gold, 1½ drachms of bicarbonate of soda. This would tone fast or slow, according to quantity of water added. Mr. Debenham had stated that the more gold used in toning the greater chance there was of permanence. Mr. HENSLER showed results on Paget's plates. He had been troubled with splashes on them. The CHAIRMAN said it looked as if hypo had been the cause. Mr. Hudson presented the Society with several old journals. Mr. FOULSON asked: Would sulpho-pyrogallol be fit to use after two years? The HON. SECRETARY said he had used some which he had had about that

period, and which had given good results. Mr. Bynoe then showed Messrs. Beck's new hand camera, the "Freda." Cut films were used, and forty could be used in the camera without holders. Mr. Fitch had made films for them which would keep as flat as glass. The camera was small and compact, and was much appreciated. Mr. BYNOE then showed his own invention of printing frames. There was no shadow in printing, and, in answer to the Hon. Secretary, said prints could not possibly shift. The discussion on the stereoscope then was resumed, and, on the question of pairing lenses, Mr. BYNOE said an expert was required to do it. The CHAIRMAN had found colours blend very well by one picture being printed differently to the other.

South London Photographic Society.—August 15, the President (Mr. F. W. Edwards) in the chair.—After the announcement of additions to the library, a N. and G. aluminium blind-shutter, now being placed on the market, was shown by the Hon. Secretary, the working of which was much admired, exposures of one-fiftieth to the second being obtained by setting an index finger. Time exposures can also be obtained. A celluloid focussing screen, of the thickness of ordinary glass, which Messrs. Newman & Guardia are now fitting to cameras, was also exhibited. Mr. H. G. BANKS, one of the Vice-Presidents, then read a paper on *The Optical Lantern, its Construction and Use*, during the course of which he gave a practical demonstration of the working of the lantern. In order to show the great heat generated when using the oxyhydrogen limelight, a penny was placed in the flame, and in less than a minute a hole was made through the coin. Attendance thirty-two.

Manchester Photographic Society.—AUGUST 11, Mr. J. Schofield (Vice President) in the chair. The leaders of the outdoor meetings presented reports of their several excursions; but, with the exception of Mr. Pogson's to Alderley, they had not been very well attended, owing, no doubt, to the bad photographic weather. Mr. COBLEY opened a discussion on the *Gelatino-Chloride Printing-out Paper*. He said he had been well satisfied with the paper when first introduced, but latterly had found a difficulty in obtaining good tones. He asked if others had met with similar results, as he feared it was some defect in the manufacture. Other members had been troubled in the same way, and it was considered rather unfortunate that these defects should occur in a paper which otherwise gave good results, and no doubt the makers would endeavour to avoid the faults complained of in future batches. Mr. H. V. LAWES exhibited a twin-lens hand camera which he had altered to suit his own ideas of what a hand camera should be, namely, easily focussed, visibility of the subject when the exposure was being made, and certainty of the shutter "going off" when required. A number of prints showed his successful manipulation. He incidently remarked that for developing the Paget plates he used the following formulæ:—Solution A: Eikonogen, ½ ounce; sodium sulphite, 1½ ounces; hydroquinone, 60 grains; potassium bromide, 8 grains; water, 30 ounces. Solution B: Carbonate of potassium, 1 ounce; water, 10 ounces. For use, 1 ounce of A to 3 ounces of B. Mr. EVANS also showed and explained his hand camera, made by himself to suit his own requirements. The construction was ingenious, each plate being contained in a separate groove running from the reservoir at the top of camera to the exposing chamber. A slide between the reservoir and chamber permitted any one plate to fall in position, the front part of camera being adjustable so as to always retain the same relative distance between lens and plate. By having a focussing glass in the end groove the focus could be obtained before admitting the sensitive plate. Mr. H. WOOLLEY gave a hint as to packing exposed plates when away for any length of time. He had found that labels on the envelopes containing his exposed plates had imprinted themselves on the negatives, owing, he had little doubt, to pressure having been applied to the packets of plates, the sensitive film being affected on the part subjected to the greater pressure where the labels intervened between the plates. The Paget Prize Plate Company sent a number of samples for distribution to the members for trial.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

A LETTER FROM MISS CATHARINE WEED BARNES.

To the EDITOR.

SIR,—Will you kindly allow me the use of your pages for an open letter to my editorial *confrères* and photographic friends in Great Britain, both professional and amateur? It is impossible for me to express individually my keen appreciation of the consideration and courtesy shown at the Edinburgh Convention and elsewhere. Let me, therefore, publicly thank each and all; and I assure my fellow-workers who may favour us with a visit next year of a warm welcome and a fitting recognition of their high position in the art-science of photography. I cannot with a clear conscience delay longer this pleasant duty of returning thanks, trusting all will be able to read between the lines that which I find it difficult to put into words. Let me also acknowledge the valuable advice and practical assistance received, which has done so much to smooth my photographic pathway. Thanks are due, in addition, for cordial hospitality, which cannot be forgotten. To yourself, and to each and all who have been thus kind, let me again tender my sincere thanks.—I am, yours, &c.,

August, 1892. CATHARINE WEED BARNES.

[We are happy to be the means of conveying Miss Barnes' graceful thanks to the photographic public, among whom she is, and has been, a most welcome guest.—ED.]

ADJUSTMENT OF HAND CAMERAS.

To the EDITOR.

SIR,—As Hon. Secretary of a Photographic Society, it has been my duty from time to time to examine and report upon various hand cameras. As my experience with some of these may be useful to both manufacturers and users, perhaps you may consider the following notes worthy of insertion in your valuable JOURNAL.

Quite recently I had a somewhat high-price camera sent me by an eminent firm of manufacturers, with a request that I would show it before the Society, test it, and report on it. After having made myself acquainted with its design and method of working, which were admirable both as regards compactness, simplicity, and efficiency, I charged the magazine and sallied forth to fire off the necessary shots.

So far all went most satisfactorily, and my favourable opinion of the camera was fully maintained.

On developing, however, troubles began, each one of the negatives being hopelessly blurred in foreground, middle, and distance, showing that no part of the picture had been in focus. There was no appearance of shaking, and when looking into the matter I soon discovered that the lens was about a quarter of an inch out of focus. The camera had adjustable focus; however, instead of the lens being in focus for distant objects when brought right back, and having movement *outwards* only for near objects, in this case there was also a totally unnecessary *inward* movement of the lens, which latter caused the blurring, the lens having been pushed right back on the assumption that that was its proper place for distant objects, there being no indication to the contrary.

As this experience of hand cameras is by no means new to me, and, I believe, of altogether not uncommon occurrence, I venture to suggest that makers should have each camera carefully examined by a competent and conscientious man to ascertain:—

1st, That the lens of the fixed focus camera really gives a sharp image on the exposed surface.

2nd, That the lens of adjustable focus camera is properly in focus for distant objects when pushed right back as far as it will go, and that the focussing scale for nearer objects be accurately marked, and the pointer correctly placed.

3rd, That the finders should accurately represent the view given by the lens on the exposed plate, and that truly vertical and horizontal lines should be drawn on the ground glass of each finder to assist when photographing buildings and other subjects having vertical or horizontal lines.

4th, In the design of all magazine cameras I think provision should be made to prevent the possibility of continuing the changing after all the plates have been exposed; the last plate should, after exposure, be properly protected so as to prevent its being exposed twice.

These points would appear to be almost too obvious to require emphasising, but the fact remains that errors do occur, and probably under the most aggravating circumstances. I believe, therefore, that too much care cannot be bestowed in the first instance on these essential points, and, if carefully attended to, much discontent with hand cameras, in every other way admirable, would entirely disappear.

I do not, of course, claim that my remarks apply to every manufacturer, or to every camera; but I do assert that even the name of a firm of repute is not always a guarantee against errors of the kind mentioned. My advice, therefore, to every photographer who buys a hand camera to take with him on his holidays is, that he should on no account leave home without having first by actual test ascertained that the camera is in every respect correct and capable of taking sharply on the plate the views shown in the finders. By taking this precaution he may save himself much disappointment and annoyance when the day of development comes.—I am, yours, &c., L. S. F.

August 19, 1892.

THE COMBINED TONING AND FIXING BATH.

To the EDITOR.

SIR,—I made up to-day a combined toning and fixing bath for chloride prints as under:—

Tungstate of soda	190 grains.
Sulphocyanide of ammonia	250 ,,
Hyposulphite of soda	2400 ,,
Acetate of lead	7½ ,,
Distilled water	20 ounces.
Chloride of gold	15 grains.

I added ingredients in order given, and all went well till I added the gold, when a dark, red-brown deposit was thrown down. What is this?

I have filtered the bath and got rid of this deposit. Is the bath affected in any way? I have made up this bath hitherto by adding the gold first, and have never found any deposit.—I am, yours, &c.,

Horsham, August 22, 1892. BERNARD LINTOLL.

[The deposit is, doubtless, gold. Add the hypo before the gold, and, on the appearance of the red precipitate, shake the solution well when the deposit will, in all probability, be redissolved.—ED.]

PERMANENCY OF GELATINO-CHLORIDE PRINTS.

To the EDITOR.

SIR,—In reply to Mr. R. Wilson, with equal care, I think gelatino-chloride quite equal to albumen in all the points he mentions, and that a greater variety of tone is obtainable than with the ordinary ready-sensitised albumen papers. As to permanency, I do not know any method of working albumen paper by which I can obtain a print that will bear the test to which I put the gelatino-chloride print. With equal care in working I should expect the gelatino-chloride to stand the test every time.—I am, yours, &c., H. G. M. CONYBEARE.

The Hut, Ingatestone, August 22, 1892.

HAND CAMERAS.

To the EDITOR.

SIR,—My BRITISH JOURNAL OF PHOTOGRAPHY only reached me yesterday. My idea for the decline in use of hand cameras is, unless you have perfect sunshine, with snap shots nearly all are failures. I have to my Kodak a shutter of my own make, which will work at any speed. I purchased of Park, the stand-maker at Haggerston, a self-adjusting tripod stand which is always at dead level. Upon this I place the camera, and expose to subject. There is nothing to regulate; the whole thing is done in less than a minute, and you are away before being noticed. I can now secure nearly every picture, where before most of them were under-exposed. What used to be disheartening is now a pleasure.—I am, yours, &c.,

Sutton, Surrey, August 19, 1892. WILLIAM GOODE.

THE DECAY OF PROFESSIONAL PHOTOGRAPHY.

To the EDITOR.

SIR,—I beg to thank you for inserting the letter of "A Professional Photographer" in your issue of August 12. I am sure it expresses the opinion of a large number of photographers. I think the time has fully come when something should be done to protect the profession generally.

My own opinion is that the dealers have done more than any one, perhaps, to injure the profession. Years ago, when the amateurs in each large town could be counted upon the fingers of one hand, those gentlemen were almost entirely supported by the profession.

When will photographers unite and start supply stores of their own? This could be done, and I venture to believe it will be done in the near future.—I am, yours, &c., A.

August 19, 1892.

To the EDITOR.

SIR,—I begin to object seeing always the amateur thrown into every discussion, and with the addition of the most complimentary adjectives as if bowing to the "almighty," even while complaining of his encroachments upon professionals.

No mention is ever made of the amateur without adding that great discoveries are due to them, and never an addition, however small, is made towards the recognition of any improvement ever made by a professional. Professionals as a rule get very little credit for an invention, while, when one amateur finds anything, the whole crowd of amateurs get the credit for it, and it may be safely said that among the amateurs of this day not one out of 10,000 would be able to add a single item to existing things.

Let us give full credit and glory to the one that makes an improvement of any kind, but another name should be given him that does it than to the 9999 who merely put a few pounds in a hand camera, and go about snapping at everything and anything in sun, rain, or fog.

Please give us a rest (even if not correct English), always raising the amateurs to unusual heights. Let an amateur be what he is. The one that is able to improve on anything, to say, photographically, on the instruments, is more than an amateur, and probably an artist mechanic; and, when the chemical line of photography is improved, that party is certainly more than an amateur, and probably a student and chemist, which most amateurs are not.

Professionals, be professionals, and raise your hearts without always bowing to the amateur. Give due credit and respect to the inventor, but to him only, and don't sprinkle with the same glory 9999 plate-spoilers, even if among them you find an occasional few making by chance some good negatives. Quality remains the exception.

This in answer to some remarks of "F. J. A.," page 542.—I am, yours, &c., A. LÉVY.

Asnières, Paris, August 20, 1892.

DISCOLOURATION OF PHOTOGRAPHS.

To the EDITOR.

SIR,—I should feel obliged with advice on the following troubles I have had the misfortune to have revealed to me after the lapse of about six to ten months, that is, the discolouring of the negative films after the short space above mentioned, which unfortunately renders the negatives next to useless. I may add, that I have from twenty to a hundred negatives to develop each day; so it is to me a serious matter, as I have never had it before when working a different method; but this way is certainly very simple and quick when there is such a quantity to get through in a day, having to develop them in batches. I use a well-known brand of plates, and develop them with pyro and ammonia only, adding bromide.

Having developed a plate, it is rinsed under the tap, and then placed in the alum bath for about fifteen minutes, then rinsed under the tap and placed in the hypo bath for about fifteen minutes. It is then perfectly cleared of all opalescence, and is apparently fixed. It is then put in the washing tank, and washed for one to two hours in fast running water.

Then there is a yellowing of the film. To remove that, I put it in a clearing bath of hydrochloric acid solution; alum, one to twenty. Then from the clearing bath it is "rinsed" (not washed), and placed on the rack for drying, and is everything that can be desired until a few months have elapsed. Then the demon shows himself. It takes its course usually from the end of the plate where it is drained in the coating of the emulsion, as it is generally where the emulsion is thicker, gradually get as deep sherry colour, and goes all over the plate. Is there any way of restoring the negatives so spoilt? The same clearing won't touch it. —I am, yours, &c., FILM FIEND.

August 22, 1892.

NEW DEVELOPERS.

To the EDITOR.

SIR,—In reply to Mr. W. A. Wright, in your last issue, I may say that I have made a number of trials in the direction which he indicates, using for that purpose Messrs. Hurter & Driffield's photometric method. Not having yet received either amidol or metol, the investigation has been kept to ferrous oxalate, pyrogallol, hydroquinone, eikonogen, and para-amidophenol. So far the following points seem clear:—1st, The exposure required varies to some extent with the developer used; 2nd, That minute quantities of bromide in the developer often have a very considerable effect, whilst larger amounts mainly affect the time of development; 3rd, Having ascertained the differences in the action of various developers upon one batch of plates, it by no means follows that with another batch, or make, the results will be similar. This last point shows clearly the cause of the diversity of opinion with regard to developers generally, and also that no table of relative values can be given, except for the particular batch of plates upon which the trials have been made.—I am, yours, &c.,

Red Hill, August 23, 1892. J. STERRY.

CAMERA BACK TURN BUTTONS.

To the EDITOR.

SIR,—Sometimes the invention of a very little thing may prove the greatest assistance. I dare say my experience has often been that of brother photographers—how difficult it is sometimes in the dark room to turn the little buttons that secure the plate and blackened piece of tin in the camera back. Often the buttons get so jammed against the woodwork of the back that it is impossible to move them with the nail of one's finger, and I have had to get out my penknife, which all means loss of time and is disagreeable, especially in a small, hot dark room. My suggestion is that all these little buttons should be made with an indentation in them, something like the slit in the blade of a pocket knife, just deep enough for the finger nail to take a secure hold of the button. There would then be no difficulty at any time at once to move the button into its proper position. Will our camera-makers give my suggestion their consideration? I am sure its adoption would be a boon and a success.—I am, yours, &c., (Rev.) E. HUSBAND.

St. Michael's Vicarage, Folkestone.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Vauneck hand camera "by Watson" wanted in exchange for first-class silver-plated banjo.—Address, W. Walker, Scotholme, Nottingham.

Will exchange Marion's *Practical Flashlight Photography* for two volumes of Humphries' *Lantern Readings*.—Address, T. J. LEHMANN, Photographer, Mold.

Wanted, No. 3 Kodak "pistol," in perfect order, in exchange for gentleman's gold keyless lever watch.—Address, JOSEPH SAUM, 19, High-street, Mold, North Wales.

Wanted, Dallmeyer's cabinet portrait lens, or 12×10 camera, in exchange for safety bicycle, silver-plated parts, balls throughout, solid tyres.—Address, A. J. BAILEY, 35A, Hindon-street, Pimlico.

Mahogany whole-plate bellows camera, three double slides, lens, and folding tripod; No. 3 Ross' wide-angle symmetrical, hand camera, or bicycle.—Address, F. T. DAY, wanted, Photographer, Hendon, N.W.

Gem camera, takes twelve pictures on a quarter-plate, locket or postage-stamp size, four lenses, repeating back, will exchange for quarter-plate instantograph, without lens or shutter.—Address, Dr. FINNY, Norbiton.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & Co.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

James Jarrett, Keynsham.—*Portraits of T. C. Warner, M.P., Ed. Strachey, M.P., and J. E. Barlow, M.P.*

W. SANDERS says: "Would you say if the word 'photoscope' has been used before?"—Yes; often.

JOHN MCALLUM.—No doubt Messrs. Hopkin & Williams will be able to supply you with chinoline red.

W. BRACEWELL.—There is nothing novel in the tones of the prints or in the method by which they are produced.

COLLODION.—If the emulsion is, as you say, perfect, no doubt varnishing the negatives will get rid of what you complain.

M. C.—Probably the solvents of the collodion had not thoroughly evaporated before the gelatine was brought in contact with them.

TRIGSTOUR.—The subject is very fully dealt with in the ALMANAC for 1888; we have not space enough to repeat the information in this column.

PRINTER.—So far as we are aware, there is no rose-tinted albumenised paper in the market that will bear a prolonged exposure to light without fading.

E. S.—Write to Mr. J. B. Spurge, care of Mr. Clarkson, optician, Bartlett's-buildings, E.C., and he will supply you with particulars of his sensitometer.

SHEFFIELD.—Until the complete specification is accepted, it is impossible to ascertain in what the invention consists, except what the inventor may chose to tell.

"ONE OF THEM."—You do not authenticate your letter in the usual way; hence its non-appearance. We do not take cognisance of anonymous communications.

HORATIO YEATES (Melbourne).—The division screen you describe is in actual use at the present time, being made by Mr. W. I. Chadwick, of Manchester. Thanks all the same.

W. WEBBER (Bristol).—The sample of paper sent seemed right, but there was too little of it to enable us to subject it to such a trial as would warrant us in reporting thereon.

J. W. R.—The platinum will not deposit, and hence it must be precipitated from the solution. By all means keep the platinum cuttings, and treat them with the solutions for recovery.

H. TEO.—Full information regarding the forthcoming Exhibition of the Photographic Society of Great Britain may be obtained of the Assistant-Secretary of the Society, 50, Great Russell-street, Bloomsbury, W.C.

G. B. BRAVERY.—The cheapest process for such a great number would be collotype, but as to actual cost of production we cannot give you any idea. Better get an estimate from a firm of photo-mechanical printers.

HYPO says: "Can you inform me where I can obtain glass etching plates, so that when the etching is completed it can be printed from, like an ordinary negative?" Messrs. Sharp & Hitchmough, of Liverpool, supply such plates, we believe.

PERPLEXED.—In copyrighting the portraits, the person referred to lays himself open to prosecution; but you have no remedy against him, not having registered the picture anterior to the piracy. This, however, will not prevent you from now selling copies of the picture

W. BRAY.—The nitro-cellulose compound, usually paper, employed in the manufacture of xylonite, or celluloid, is not at all suitable for the manufacture of collodion for photographic purposes. The material is not what is known as gun-cotton or as pyroxyline, but xyloidine.

R. RIDLEY.—Two thicknesses of canary medium will be quite sufficient in a lantern with a good size fish-tail burner—that is, with ordinary plates; but if they be orthochromatised with eosine or erythrosine, the medium should be supplemented with a thickness of ruby glass or fabric.

H. W. B.—If the purchaser of the business repudiates you as his servant, and the seller did not give you notice to terminate the engagement, you will, we suspect, have to look to the latter for your salary. Your engagement was with him, and you say you have made none with the new man.

PHILIP NEWMAN.—Your better plan, we think, would be to submit the negatives to some such firm as Messrs. Valentine, of Dundee; Messrs. Frith, Reigate; Messrs. G. W. Wilson & Co., Aberdeen; or Mr. Spooner, Strand, London, who all engage in the publication of photographic views. Thanks for the enclosure.

SILVER.—Both the formulæ referred to will give excellent results if the solutions are carefully prepared. Pure material must be used. The potash is that known as pure by alcohol, and does not explode if dissolved in water. You are probably thinking of metallic potassium. No boiler or battery is, of course, necessary. The streaks you complain of arise from the glass not being chemically clean.

T. WATSON says: "I am going to do some oil-colour paintings, and I should like to do them on some etching like ivory, if there is such a thing, as I think ivory would be too expensive, as I shall sell them cheap. Could you inform me if there is anything similar to ivory, and where I could get it?" The British Xylonite Company, of Homerton, may possibly be able to supply the desired material.

A. MALLETT (Christchurch).—To call a collotype a photograph is perhaps somewhat of a misnomer, the more correct name being possibly "phototype," a term much used abroad. We do not think, however, that there is anything seriously misleading in the words "permanent photographs" applied to collotypes, since the production of the latter depends upon the employment of photography, while their permanency is at least as much assured as that of pictures produced by any other printing process. "Phototype," or "photo-collograph," however, would be a decidedly better name, to use in distinguishing them.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—Thursday, September 1, Outdoor meeting, Gilsland and Naworth. Leader, M. Auty.

PHOTOGRAPHIC CLUB.—Club outing for Saturday next, Snaresbrook; train leaves Fenchurch-street at thirteen minutes past two. Subjects for discussion:—August 31, *Optical Glass.* September 7, *Enlarging.*

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—September 1, Members' Open Night. 8, *Is there any Adequate Theory of Reversals?* 10, Outing to Greenwich; leader, Mr. A. Haddon. 15, *Various Printing Processes,* Mr. B. Foulkes Winks. 22, *Photographic Limits,* paper by Miss Catharine Weed Barnes, of New York.

THE results of the examination in photography by the City and Guilds Institute have been made known, and we note that the Polytechnic School of Photography again sends up the recipient of the highest honour. Mr. S. J. Beckett, a student at the course held by Mr. W. E. Debenham at the Polytechnic Institute last winter, has gained the silver medal and first prize in the Honours department, and three students from the People's Palace, under the tuition of Mr. C. W. Gamble, so long associated with the Polytechnic, have gained the silver and two bronze medals in the ordinary division.

HACKNEY PHOTOGRAPHIC SOCIETY.—The arrangements for September are as follows:—6, Ordinary meeting. 10, Excursion to Sewardstone; meet at Chingford Station at half-past two. 13, Discussion on Exhibition. 20, Ordinary meeting. 24, Excursion to Hampstead. 27, *A Holiday in the Isle of Man,* W. Fenton Jones. The Society purposes holding the Annual Exhibition at the Morley Hall, Hackney, about the first week in November, on the same extensive scale as last year. The classes will be:—A, Members' work since last Exhibition. B, Members' work before last Exhibition. C, Members' Excursions. D, Portraiture and Genre (members). E, Members' Lantern (six). F, (Open) Lantern Slides (six). G, (Members) Stereoscopic. H, (Open) Stereoscopic. I, (Open) Portraiture and Genre. J, (Open) Landscape and Seascape, &c. Prints may be by any process, direct or enlarged, opals and transparencies excluded. Forms will be ready at the end of September.

ON Thursday last the staff of assistants employed by Mr. W. Barry, photographer, of Hull, held their annual picnic. Leaving the studio in two brakes, about half-past nine, after a very pleasant drive through about the only bit of picturesque scenery and villages the district can boast of, to wit, Westella and Swaneland, the destination, Welton, was reached by noon. Substantial viands and luxuries were provided by the Welton caterer, Mr. Giddy, and then rounders were indulged in amid the verdure and beauty of the dale. Then came the event of the day, the long-looked-for cricket match between the sides "Palette and Brush" *versus* "Hammer and Saw," the former winning easily. This humorous and exciting match put every one into the best of spirits, and the day was deemed to be much too short, as the interval to its anniversary next year is now felt to be much too long. Justice was done by sharpened appetites to the host's ample table a second time, and eventually the setting-out place of the morning was safely regained by half-past nine in the evening, all voting it a capital twelve hours.

A COMPETITIVE Exhibition of photographic work, in connexion with the Bedford and District Amateur Photographic Society, will be held in the Large Hall of the Bedford Modern School (by the kind permission of the Rev. Dr. Poole, Headmaster) on Tuesday, Wednesday, and Thursday, October 11, 12, and 13. The officials are:—President: Rev. H. Victor Macdona, M.A., Hilbre Grange, Bedford. Hon. Secretary and Treasurer: W. E. Ison, Hughenden, River Crescent, Bedford. Committee: Rev. H. Victor Macdona, M.A., (President), *ex-officio,* Deputy Surgeon-General A. H. Beaman, Mr. H. W. Stewardson, Mr. Alexander Kirby, Mr. P. Hill, Mr. Montague Troup, Mr. W. E. Ison (Hon. Secretary), *ex-officio.* The Exhibition will be open to all amateurs, and it is also intended to make arrangements for a special class of photographic work for the members of the Bedford Schools. A series of awards will be granted, which will chiefly be of an honorary character, to the successful competitors. Mr. Andrew Pringle will be one of the judges. The Council will also arrange for a series of popular lectures, illustrated with the oxyhydrogen limelight lantern, during the three evenings of the days on which it is appointed the Exhibition shall be open.

THE CONVENTION GROUP KEY.—*No.* 107 *represents Mr. N. Alker; while, instead of "Bickersteth," No.* 21, *read "Mr. H. M. Hastings."*

JOURNAL OF PHOTOGRAPHY.

No. 1687. Vol. XXXIX.—SEPTEMBER 2, 1892.

CELESTIAL PHOTOGRAPHY WITHOUT AN EQUATORIAL.

We well recognise the necessity for an equatorial when a time exposure is to be given to a celestial body, as this, in virtue of the diurnal rotation of the earth, passes across the field of the telescope with a rapidity determined by the focal length and power of the instrument; and it has been pointed out in this Journal that, in order to depict some stars which are altogether invisible to the eye, even with the aid of a telescope, an exposure of an hour has been found necessary.

And yet, in the case of some of the more luminous celestial bodies, the amount of light radiated is such as to render quite possible the employment of a drop shutter, by which the necessity for an equatorial is abrogated. We have before us an admirable example bearing out this fact in the form of a telescopic photograph of the moon taken by Professor W. C. Gurley, M.A., Director of the Observatory of Marietta College, Ohio, U.S.A. It measures slightly over three inches in diameter, and is a direct photograph—that is to say, it is direct in the sense of the magnified image having been produced by the eyepiece of the telescope, and not by after-enlargement of the image.

There are two features of interest in connexion with this photograph; the first to which reference has been made, that of its having been taken without an equatorial stand; the second being the sharpness of the picture, notwithstanding that the object-glass was that of a properly corrected astronomical telescope.

We have on several occasions pointed out that when a lens is properly corrected for visual purposes—*e.g.*, as in an object-glass for a telescope—this correction will not serve for photography. In this sense achromatism, or freedom from colour, is different from actinism, which latter term implies the coincidence of the chemical and the visual foci.

There are two methods by which the objective of a telescope may serve the requirements of the photographer. The first is to ascertain by trial the distance at which the sharpest visual focus is situated from the sharpest photographic focus. The objective being of necessity over-corrected, this places the latter, or photographic focus, somewhat behind that for visual rays. We need scarcely say that when once this difference is noted it is a constant one for all distant objects. The second method consists in interposing a ring between the crown and the flint elements forming the object-glass, so as to effect a slight separation of them. This will undoubtedly weaken the power of the concave flint, and make the object-glass actinically correct. As in the former case, it has to be done by trial, for we know of no rule that can be applied that will apply to any or every objective indiscriminately. We are aware that in a few of the more important refractors of the world—the Lick telescope for example—a special crown glass has been provided for photography which is interchangeable with the crown employed for visual examination of the objects in the heavens.

A point of interest here intrudes. Assuming that there is a loss, no matter how small, in the definition obtained in a telescopic image when the photographic plate is placed in the best ascertained position for ensuring sharpness, and which may, as recorded of the Sheepshanks telescope, be an inch beyond the visual point of sharpness, the question arises in the event of the elements of the object-glass being brought, by a ring separation, into actinic correction, what would be the result as regards definition between the photographs produced by these two systems?

We now return to Professor Gurley's photograph of the moon. Although printed on paper, its sharpness is sufficient to bear examination through a magnifying-glass, which is rather surprising when we state that the exposure was not instantaneous (as we recognise the term), but lasted for three-quarters of a second, during which time the moon must have made a sensible angular progression. The object-glass of the telescope is six and and a quarter inches in diameter, and is of great visual excellence. The amount of separation of the components to effect actinic correction was found to be $\frac{9}{32}$ of an inch. A Huyghenian eyepiece of a magnifying power of sixty-five diameters was employed, as Professor Gurley finds it preferable to produce the enlargement in this way rather than by an after-process of enlarging the negative. Of course an extremely rapid plate was used. A 5 × 4 camera was affixed to the eyepiece end of the telescope, and on a partition just beyond the eyepiece was fixed the exposing shutter, actuated by a pneumatic ball. The plate was developed with pyro-soda, the pyro being reduced to one-half the quantity recommended for a normal exposure.

On the subject of photographing by a telescope (and we now mean its application to terrestial subjects) it would be interesting, in an historical point of view, if we could obtain from Mr. B. J. Sayce, or Mr. George Thomas, some details, other than were published at the time, of a telescopic view of *some* subject situated three miles from the camera. This was in 1854 (we quote from memory), and we think it was shown by Mr. Sayce. This goes far, especially in conjunction with Hartnup's telescopic photographs of the moon, taken about the same period, to assign the place of honour to Liverpool as the scene of the first application of the telescope to photographic purposes.

PHOTO-DYEING.

Processes for the production of coloured positives on paper, silk, and other fabrics, by means of the application of a species of dye to the silver image, have long been familiar to photographers, although it is true they have never at any time been extensively employed. Citing, in this connexion, the well-known ferro-prussiate process, which, nevertheless, differs essentially from those methods we have in mind, as probably the simplest way of producing paper or linen positives in colour, we may also note that, by the carbon process, in which a considerable variety of differently coloured pigmented gelatines are used, a great number of pleasing colours are obtainable. These methods, however, do not fall under the description of dyeing processes, with which we now propose to deal, in the hope and belief that they may open up the possibilities of an occasional departure from ordinary methods of positive printing in general use.

As typical of the means formerly adopted for colouring the silver image on fabrics, we will select for outline the following plan, which was in vogue about thirty years ago. Silk was first treated with a solution of gelatine, ammonium chloride, powdered alum, and distilled water, and after being dried was rolled, an operation which was repeated after the surface had been dried and sensitised. The picture was then printed, toned, fixed, washed, and dried in the ordinary manner, when it was immersed in a ten per cent. solution of acetic acid, to which a small quantity of the desired colouring matter was added—for red, eosine, for blue, bleu de nil, being employed, and so on for other colours as required.

Possibly it is not quite accurate to include even the foregoing plan among dyeing methods *per se*, inasmuch as the silver deposit simply undergoes a change of colour—is, in fact, "toned"—the term, perhaps, being more strictly applicable to certain adaptations of the bichromated gelatine process with which the employment of a dye is conjoined. In relation to this department, therefore, of the subject, it is of interest to note that M. H. Fourtier, in a recently published work on *Glass Positives*, has exhumed an old process of M. Charles Cros for the preparation of coloured positives on glass, which has the merit of simplicity in its favour, and the further advantage that, for the preparation of the bichromated surface, a spoiled or light-struck gelatino-bromide plate, or even an old developed negative, may be utilised. In the former case, the silver bromide must be dissolved out of the film, and the gelatinised glass thereafter plentifully washed; while, in the latter, the picture must be removed by a solution of potassium ferridcyanide and hypo, equal care being, of course, observed in the after-washings to leave the gelatine as chemically clean and stainless as possible, plates being selected that have not been passed through an alum bath. The dried film of gelatine is next sensitised on a three per cent. bath of ammonium bichromate for from three to five minutes, and, after the excess of bichromate has been removed, is dried and printed in the frame behind a positive. The plate is then well washed, again dried, when it is treated with a solution of the colouring matter which attacks those portions of the gelatine which swell. Those parts of the gelatine image absorb the colouring matter proportionately to the intensity of the light exerted on them, thus giving a positive from a positive. The excess of dye is next removed by washing, and the picture finally dried. For red, M. Charles Cros recommended carmine, fuchsine, or eosine; for yellow, picric acid or alkaline picrates; for blue, Prussian blue or aniline blue.

More recently, Mons. A. Villain, of Paris, has worked out a photo-dyeing process, somewhat on the lines laid down by M. Charles Cros, and applicable only to textile supports; and it may be remembered that we briefly drew attention to it in our issue of July 1 last. Since then, M. Villain has considerably amplified the practical details of the process; and as, from an inspection of some specimen pictures on linen produced by its aid, we conceive it to be of great possible value as a practicable photo-dyeing process, we shall now place a more complete description of it before our readers, gathered from a communication which M. Villain has just addressed to our esteemed French contemporary the *Paris Photographe*.

M. Villain claims for the process under notice that results in a great variety of tints may be obtained, and that the images are unaffected by light, acids, and alkalies. He sensitises paper or other fabric in a solution of 1000 c.c. of water in which 50 grammes of ammonium bichromate are dissolved, and to which, as a mordant, 5 grammes of ammonium metavanadate are added. The paper is dried at a temperature not higher than 25° to 30° C., the whites being discoloured at anything much greater. The sensitised paper or fabric is exposed under a negative until the details are well out and after the unfixed chromium salt has been removed by repeated washings, is then immersed in a solution of the colouring matter, which is maintained at boiling heat for fifteen or twenty minutes. If, after the dyeing, the whites are impure, either a warm bath of soap and carbonate of soda is used, or a cold solution of lime chloride acidified with hydrochloric acid. The print is completed by washing in (if the lime has been used) a slightly alkaline solution.

The colouring matters which M. Villain employs are chiefly anthracene derivatives, several of which we specified when formerly referring to the process, among them being alizarine red, alizarine violet, blue, and black, each of which affords a variety of tones according to the particular mordant employed, whether in the paper or in the colouring solution. In addition to these, other colouring matters are available, such as gallo-flavine, a product of the oxidation of gallic acid, alizarine yellow, green, and several more, affording an enormous range of tones.

It is obvious that the possibilities of such a process of photo-dyeing to which M. Villain has devoted his attention are very great, while the application and extension of the principle deserve attention. It will be noticed that the intervention of a gelatine film is unnecessary, and that it also differs from the process of M. Charles Cros in not being a direct method of reproduction, *i.e.*, one yielding a negative from a negative or a positive from a positive. As easy means for the production of coloured positives by dyeing, both methods are equally worthy of regard—the one for glass, the other for fabrics.

ONE LENS FOR ALL ANGLES.

We have had an opportunity of looking through an album containing a series of charming photographs—portraits and landscapes, dainty vignetted "bits," broad expanses of champaign embracing a narrow angle of view, and, again, street scenes including a wide angle. The pictures were mounted with taste and judgment, and though all were small—some were even not more than three inches across—yet the whole collection was a veritable set of pictorial gems. From it many lessons could be learnt, first among them the great desirability of cutting a

print down to the exact extent that would satisfy the most exacting critic as to composition and design. It cannot be denied that the practice, encouraged by so many exhibition committees, of fixing the particular size of photographs to be displayed, or, rather, entered for competition, has materially cramped the artistic effect capable of being obtained from a particular negative. We appeal to all who have been judges at photographic exhibitions whether there have not come before them, in the exercise of their judicial functions, very many photographs utterly ruined by the inclusion of portions of subject that offend against artistic propriety, and that ought to have been ruthlessly cut out, even though the view were reduced to one-half the size. But then, if this had been done, the collection would have been disqualified, so that, right or wrong æsthetically, the full tale must be given, the exact amount of square inches reached, if not over-passed. It may be said that the skill of the photographer is shown by the way he places his camera so as just to include what should be included and to leave out what would injure the picture. To a certain extent this is true; but, on the other hand, the possible standpoints are often restricted to a very small area, and, again, no power can expand a view that, for example, cuts up beautifully to a size of, say, ten inches by three to a ten by eight proportion. Hence it is evident that offering a medal, for example, for a set of six 10×8 views must cause either the exclusion of many a beautiful picture or the inclusion of many an unbeauteous accessory or component. It must not be supposed from these remarks that we suggest the abandonment of classes governed by size; neither do we suggest their retention. Our present purpose is to show one of the evil effects brought about by the system, and thus, at any rate, render it open to discussion, and suggestion for means of increasing the elasticity of the rules governing the boundaries of pictures.

These remarks have a further object. Once granted that in the taking of views the principle of having a collection a given number of inches long, and another fixed number broad, is by no means necessary to effect, and is often detrimental to beauty, and the ground is cleared for our main object. Amateurs who take photographs for the mere love of the work, and to produce a photograph which they hope will prove that "a thing of beauty is a joy for ever," form the large majority of users of the camera, and they need not be trammelled by any rules as to size. Those of them who cannot spend much money over their hobby, and who often lose a picture through not having a suitable lens, may value the suggestion that it is quite possible to work with one lens only, and yet obtain views of any practicable angle whatever, from the shot required in street work to the diminished range desirable in many landscape effects. The only condition requisite is, that the actual size of the view is not to be fixed. Two requisites are involved—the use of a reversing back and of a plate of maximum size. Given a camera of the selected size and a suitable lens, all that is requisite is to see that the view to be taken is centrally placed on the plate, and often to make the actual selection of view from the negative itself.

It will scarcely need pointing out that the lens will need to be chosen from the wide-angle class. What will embrace a wide angle will necessarily include a narrow angle. The only objection of importance that can be raised to the scheme is that the general average of size must be small, unless inner frames be used—a plan fraught with inconvenience, and unless plates of such large size be chosen that the cost of plates alone would be a serious item. It is true that to use a 12×10 plate to take, say, an 8×6 view would be wasteful; yet would it not be far better to waste that value of plate rather than risk the inclusion of objectionable features in the endeavour not to "waste" a plate?

The subject is a very large one, and is capable of being argued on many grounds and seen from many standpoints. In an article like the present, brief suggestions only can be made, and we will conclude by giving one or two practical details. If a lens (one of the wide-angle class) be chosen with a focus about two-thirds the length of plate, there will then be an average size of picture taken of length equal to the focus, i.e., two-thirds the length of the plate will be "wasted." A view embracing a very wide angle will need the whole-plate, one including a small angle only (unless one component only of the lens be employed) will only use one-half the length of the plate. Take the commonest size of all—half-plate. If a lens of four and a half inches focus be chosen, the majority of views taken will average about four or five inches; a street view may need all the plate, a landscape might possibly be best cut down to three inches. But what a gain there would be! Far better than a uniform longitudinal space would be the wise, careful, and artistic appropriation of just, and only just, what is needed to compose a picture. Apart from the one-lens question, let some of our readers act upon and report upon our suggestion.

ACCURATE EXPOSURES.

How frequently is the remark heard, in speaking of a negative or photograph, "Oh, that had a second and a half, but a second would have been quite sufficient;" or, again, "I gave that eight seconds in a very bad light, but it would have done with ten." Perhaps, in the case of an "instantaneous" exposure, the statement may be varied to "The exposure was one-tenth of a second, but you see it is overdone; one-twentieth would have been ample." We venture to assert that no such ideas of extreme accuracy prevailed amongst the workers of ten years ago, and, to go back still another decade, such remarks would have been considered absurd, even when due allowance had been made for the different sensitiveness of the plates of that day. The so-called "latitude of exposure" of the dry plates of twenty years ago was far too great to render such trifling variations in exposure of any importance whatever, while even wet plates, which did require a close observance of accuracy, would scarcely, we think, have been seriously affected by similar departures from the exact time, in skilful hands at any rate.

It is very certain that the latitude of exposure of gelatine plates of to-day is not less than it was ten years ago; on the contrary, the change, if any, is rather in the opposite direction, and any of the good commercial brands are more easy to manage, we believe, in the matter of exposure, than was the case at the period we mention. For one thing, some modern plates are, as a rule, if not invariably, more thickly coated with emulsion than formerly, and it stands to reason that a film rich in silver must give an image possessing proper printing gradation more easily than one in which the silver present only just suffices to give printing density under the most favourable circumstances. With a film rich in silver, over-exposure, of a far more serious character than is involved in the remarks we have quoted, only necessitates a longer application of the

developer, with or without the use of an additional quantity of restrainer, whereas the poor, thin film, under such circumstances, produces the flat, unsatisfactory result that gave rise to the term "burnt up." In case of under-exposure, the thickly coated film, by the use of a suitably modified developer, enables the details to be "coaxed out" without rendering the lights too dense; but the poor film, under such treatment, yields nothing but an equally poor image, in which, whatever may be the condition of the high lights, the shadow details possess no printing value.

It was not, however, all the plates of ten years ago that were of the unsatisfactory character we have spoken of, for some of them, although giving apparently much more transparent images, contained fully as much silver as the average modern plate. This transparency of image was due to the nature of the deposit, the bromide of silver being in an extremely fine state of division, in which condition the colour of the negative had much to do with its printing density. On the other hand, when newer methods of emulsification came into vogue—notably the "ammonia process"—the deposited bromide became much coarser, and it was then that poverty of film began to be felt. We do not refer to the ammonia process as being the only one that gave coarse and poor films, for the same result occurred from over-boiling, as well as in the different precipitation methods that were tried, but none of which ever came into general use. It was the struggle after extreme sensitiveness combined with the attempt to economise that gave rise to the class of plate that was deficient in "latitude," for such films when tried in the laboratory with the sensitometer, a standard-camera exposure, or under a negative at a fixed distance from a gas flame of tolerable uniformity, might give a satisfactory result, the exposure being a "correct" one, and yet altogether fail in the studio or field from the inherent want of latitude.

But with ordinarily good plates we have made equally good negatives from very varying exposures. On one occasion half a dozen plates came into our hands for development, all having been exposed upon the same subject, which was required for a special purpose, and, in order to secure at least one negative, each plate had received a different exposure, these varying in value from one to about six; but, unfortunately, the memorandum of exposures was lost, and we had no information whatever upon that subject; nevertheless, each plate produced a good negative, and it was impossible to say with certainty which had received the longest and which the shortest exposure. A similar result occurred on another occasion, when, with a view of giving a lesson in development, we exposed a series of plates for periods varying from one to ten; but in development we instinctively treated each plate in the best manner to produce a negative with a precisely similar result, and, although our lesson may have been useful, so far as it showed the possibilities of "latitude," it signally failed in demonstrating, as we intended to do, the peculiarities of over and under-exposure.

One more example will show the practical utility of latitude of exposure. Dealing with plates of such different degrees of rapidity as ———'s "Instantaneous," and the same maker's "Ordinary," we on one occasion went out with some of each kind in our slides, and carelessly exposed the "instantaneous" for the slower ones, giving the more rapid exposure to the latter. Thanks, however, to their elasticity in exposure and development, aided, no doubt, by our invariable practice of not cutting the exposure, every plate that day produced a good negative; it is needless to say we discovered the mistake on arriving home, and treated each plate accordingly.

As we have already remarked, there is not the slightest reason to believe that our modern plates are in any way inferior to those of earlier years in their capacity for meeting wide variations in exposure. Why, then, this supposed necessity for such extreme accuracy? The difference between one second and one and a half is an increase of fifty per cent., but this in comparison with one to ten is a mere nothing, yet many operators at the present day profess to find it produce an appreciable effect on their results. We have little hesitation in ascribing the cause to the introduction of "one-solution" developers and exposure meters, both of which, though useful in their way, are calculated to reduce development — scientific development—to the position of a lost art.

The one-solution developer, incapable of any modification beyond mere dilution, necessarily requires a closer adherence to some limits between which the exposures are made, or, in other words, entails greater accuracy. This in its turn entails in inexperienced hands the adoption of some instrument or method by which the exposure can be correctly estimated, and, when this is available, "one-solution" developers become thoroughly practical, though photography then becomes a merely mechanical process, and automatic development a fact. But, since the perfect "exposure meter" readily available for outdoor use has still to be invented, the fact that so many good results are obtained with fixed developing solutions argues rather in favour of the latitude of the plates than of the power of such a developer to meet all requirements. Where the "one solution" is employed, however good the plates, some little care must be exhibited in timing the exposure; but even then it is somewhat ridiculous to make a parade of a non-existent necessity for extreme accuracy. When it is alleged that a single second would have produced a better result than a second and a half, if the negative really show signs of over-exposure, it is more than likely, even with a single-solution developer, that a quarter of a second would have been nearer the absolutely correct mark.

These single-solution developers are undoubtedly useful under certain circumstances—that is to say, when the exposure has been within measurable distance of the "correct," whatever that may mean; but they are seldom of much avail when, from accident or necessity, more than usually wide departures are made from the normal, as in cases of accidental over-exposure in an excessive degree, or in photographing very rapidly moving objects. Then—and, indeed, for all classes of work—nothing has yet appeared in the shape of a developer than can compare with pyro and ammonia intelligently used; others of the newer developing agents, when used with varying proportions of alkali and restrainer, give a certain amount of power in varying the result; but none as yet come up to pyro, with which it would be utterly absurd to talk about a variation of fifty, or even a hundred, per cent. in exposure producing such an effect as is claimed by some.

In conclusion, we would strongly urge those who would thoroughly understand the theory as well as practice of development, and at the same time secure the largest proportion of successful exposures, to eschew single solutions, and to adopt, if not the ten per cent. system, at least one that will permit of the modification of the developer according to circumstances. Otherwise, the fancied necessity for extreme accuracy in exposure will undoubtedly become real, and one of the greatest powers of development absolutely lost.

The Eastman "Solio" Paper.—We understand that the Eastman Company intend for the future to call their gelatino-chloride paper by the name of the Eastman "Solio" Paper.

Heat and Photo-mechanical Work.—The intense heat of the past month, both at home and abroad, caused many inconveniences in the practice of photography. Studios, particularly those of the old "glass-house" type, have been almost unbearable, alike to sitters and operators. Great as was the heat here, it was still greater on the Continent, where, we are informed, some of the largest photo-mechanical establishments, whose work is dependent upon bichromated gelatine, were compelled to suspend operations entirely for a great portion of the month. With the thermometer at or about 100° Fahr., the successful dealing with bichromated gelatine in any form becomes next to an impossibility.

Definition in Portraiture.—Mr. J. Nesbit's defence of good definition in portraiture, delivered the other night in the course of some remarks on outdoor portraits before the Photographic Society of Great Britain, was supported by the cogent argument that he took such portraits as he saw them—that is, clearly defined—and not in the blurred manner now prevalent. No simpler, and at the same time more powerful, defence of sharp, or, at least, good definition in portrait photographs could, in our opinion, be adduced. It is only rational to suppose that such pictures should in the prints appear not less sharp than the eyes see the original, so that, if all modern photographers take portraits in the manner of Mr. Nesbit, it clearly follows that blurriness is, after all, a defect of the vision, and not due to any inherent objection to good definition *per se*. Some experiments on the eyesights of photographers who favour out of focus would be very interesting.

The Value of Retouching.—At the same meeting Mr. Nesbit paid a deserved tribute to the value of retouching under certain circumstances. He exhibited two portraits by himself of Mr. E. Dunmore taken with a lens of the rapid symmetrical type, the untouched one showing the corrugations of the face in a painful degree. In the other one these corrugations had been rapidly and skilfully removed by Mr. Redmond Barrett, Mr. Nesbit remarking that the result was most pleasing, and others testifying to the excellent manner in which the likeness had been preserved. Evidently, with outdoor portraiture, the services of a retoucher are not only useful, but, more often than not, are of positive necessity.

Intensifying "Blue" Prints.—Captain Himly recommends, for imparting greater intensity and brilliance to blue prints, an immersion in a solution of a ferric salt—perchloride of iron, for example—of a strength of five per cent., the prints afterwards being well washed.

National Association of Professional Photographers.—Continuous efforts are being made by the executive of this Association to induce professional photographers to take up membership in order to further those objects in which the profession as a whole is vitally interested, such, for example, as the revision of the law of copyright, relations with manufacturers, the right to the negative, and so forth. We are constantly publishing letters ventilating professional photographers' grievances, which, we may point out, would possibly be the sooner redressed if united action were taken. Hence our suggestion to these and others to join the National Association, whose Secretary, Mr. D. J. O'Neill, of 47, Charlotte-street, Birmingham, will be happy to forward full information and particulars. As we stated on a former occasion, the next annual meeting of the Association will probably be held in London some time during the Exhibition of the Photographic Society of Great Britain.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

As already announced, the Exhibition of the Photographic Society of Great Britain will open on Monday, September 26, and remain open until November 10, being inaugurated by the usual *conversazione* on Saturday evening, September 24. Medals will be placed at the disposal of the Judges for the artistic, scientific, and technical excellence of photographs, lantern slides, and transparencies, and for apparatus. The Judges are Messrs. F. P. Cembrano, jun., W. E. Debenham, W. England, F. Hollyer, and J. Traill Taylor, with, as scientific experts, Captain Abney and Mr. Andrew Pringle.

Entry forms, which may be obtained of the Assistant Secretary, Photographic Society of Great Britain, 50, Great Russell-street, Bloomsbury, W.C., should be sent to him by post on or before Tuesday, the 13th inst., or delivered with the exhibit on the following day at the Exhibition Gallery, 5a, Pall Mall East. These particulars may serve to answer numerous inquirers who have written us in reference to the latest date for sending in exhibits, ample time, it will be observed, remaining for that purpose.

We anticipate an Exhibition in no degree, as regards excellence and number of exhibits, inferior to any of its predecessors, and are confident that it will attract the support of all who are sincerely desirous for the advancement of photography. The American exhibits are already more numerous than hitherto.

CONVENTION JOTTINGS.—VI.

A Run through Some of the Scotch Studios.

MARSHALL WANE (Edinburgh and Ayr).

Our next visit was to Mr. Marshall Wane's studio in George-street, Edinburgh. Before coming to Edinburgh Mr. Wane held a world-wide fame as a first-class photographer in Douglas, Isle of Man; at that time for large, direct pictures he pretty well took medals at every exhibition that he entered for competition, and, to our knowledge, from his studios have emanated artists that now broadcast fill first positions in the highest-class businesses in the profession. Seeking a larger and more extended centre for the prosecution of his business, Mr. Wane selected Edinburgh as a likely venture, and selling out a business that had increased to considerable dimensions for the size of the place—viz., Douglas—he came and settled in the capital of the North.

Within the last three years he has further extended and opened a charming studio at Ayr, a favourite summer resort.

The Edinburgh place, as can be well understood, is one of the best of its kind, the entrance-way and showrooms being hung with specimens of his usual fine work; prominent amongst these are pictures highly finished in water colour, which is a large and profitable part of his business, large portraits in oil also being considerably in demand, whilst platinum, bromide, and carbon works come in for their full share of attention.

Those who visited the Edinburgh International Photographic Exhibition will remember the series of large platinum pictures exhibited by Mr. Wane—a collection of pictures that showed great excellence of workmanship, both artistically and technically. As we have said, Mr. Wane was one of the first and most successful photographers that entered the field with large direct portraits—that is now many years ago—but there is no lagging behind even now, for he is ever amongst the first to introduce the latest novelties to his numerous customers.

His showrooms are artistically arranged, the decorations being soft and subdued in tone, and his studio is furnished with backgrounds and accessories of the latest type. On visiting Mr. Wane's Ayr studio, we found it a marvel of completeness, and thousands of pounds must have been expended before such an establishment was so fitted and furnished ready to receive those clients for whose comfort it was enriched and decorated.

These business premises are in a large self-contained house situated in one of the finest terraces in Ayr, one of those select spots where no business is supposed to be conducted, and consequently no specimen cases or advertisement pictures of any kind are on view. In such a place the connexion must be made without the aid of such. All sitters who come to be photographed come with intent, as no indications are made whereby chance customers might be induced to drop in.

The studio and workrooms are built in the garden at the back of the main building, and joined by corridors to the front premises.

The first room on entering is the business-room, which partakes much of the feeling of a country house, and looks business. The

following rooms are showrooms, and we found these fitted in rather a novel way. Broad panel screens running on castors, so that they could be moved to any point or light, are ranged round these apartments, and each of these movable screen panels is tastefully hung with pictures—no crowd or excess of work, but beautiful things tastefully arranged. Behind these rooms is the studio, which has been faultlessly arranged as regards lighting, decorating, and accessories.

From the quantity and quality of the work here turned out, it seemed to us that the quiet of the exterior did not seem to retard the progress of considerable working operations within.

Mr. Yerbury's Studio (3, Hanover-street, Edinburgh).

When in Edinburgh, we had occasion to visit Mr. Yerbury's studio at 3, Hanover-street. Wishing to change some Eastman films, and his place being quite close to our hotel, we, knowing his genial disposition, went up for the use of his dark room. Not having been in his place before, however, we were quite charmed with the appearance of the compact little place, containing as it did the necessary room and appliances for a considerable trade in a compass that needed everything to fit in nicely if the work had to be got through expeditiously, for besides the usual portrait and group work, of which we saw many fine specimens, we found Mr. Yerbury producing opalines, —fishwife photographs and other popular subjects—which are sold as souvenirs, and which he supplies to the shops in the city. In a favoured place like Edinburgh there must be a large demand for such mementoes by the tourist and stranger, and Mr. Yerbury seems to have struck the groove.

His place is composed of two flats, the show and business rooms being immediately below the studio and workrooms flat. All the work is under the personal supervision of Mr. and Mrs. Yerbury.

We were received with great kindness by both, and their extreme courtesy and eagerness to help us will always be a pleasure to think of.

Mr. Warneuke's Studio (Sauchiehall-street, Glasgow).

Being in the north, we made it our business to go further afield than Edinburgh, that queen of cities; so next we betook ourselves to Glasgow, the commercial capital of Scotland, to see what was being done in that metropolis of the west, and here we found, what we have always found on former occasions, everything spinning along with an energy and "go" peculiar to the people and the place—no leisure about them when at their work; they mean business, and look it.

Our first visit was to Mr. W. M. Warneuke, who has now two places running, the one at 127, Sauchiehall-street, this one being the business premises in which he has been located from his start until May, when he acquired another place at 153, Sauchiehall-street, a few doors further up on the same side of the street. He is now going to run both places, the one at 127 under the title of "The West-end Photographic Studio," and the new place as "Warneuke's Studio." The old studio was constructed and conducted on old and familiar lines, but with the 153 premises Mr. Warneuke has made quite a new departure. At the time of our visit the finishing touches were just being put upon it, and very shortly it was to be opened to the public.

The place when he took it had a front shop, with large window and doorway. These he has had cleared away, making an entrance-way equal to the width of both, and in length right in to the stair that leads up to the showrooms. From the street all along this passage-way the roof and uprights are constructed of woodwork, all wrought in the fancy checked Alhambra patterns and style, looking remarkably solid, yet light and graceful. Both sides of the entrance-way, and reaching as far as the stair, the walls are fitted with plate-glass cases, large and free as windows, where the largest pictures can be exhibited with ease and grace, the uprights between the panes of glass being of the same style and finish as the other Alhambra work, the space between the cases, right and left, being so great as to allow of any likely number of people viewing the contents with ease and comfort, the whole effect of this unique arrangement being "catching" and pleasing to the eye, and arrests attention at once.

The door at the foot of the stairway is also very chaste in design fitted with stained glass, with a large bevelled oval of patent plate fitted in the centres.

On the first landing we reach a large picture gallery, lighted from the top, which has been furnished and decorated as principal showroom. In the way of wall decorations we here came upon what, to us, was quite new. To all appearances, the walls were covered with what seemed to us a brocaded silk damask of a dark greenish-blue colour; but, on closer inspection, we found the surface was oil paints. The effect, which is very pleasing, is, however, produced by first covering the walls with a special kind of white lace curtain in the same manner as you would paper them, and then the oil paint is applied to the surface of the fabric, thus producing the rich, silky effect that arrests the eye.

The pictures hung are artistic, appropriate, and not too crowded. The seats are Turkish ottomans, and the carpet is velvet pile. The woodwork is all of the Alhambra pattern that we have previously noted—in fact, this style of woodwork is carried right through the whole place, including business rooms and studio, and, wherever partitions intervene, these are all fitted with stained-glass windows.

The business and dressing rooms are on the same flat as the showrooms. With special attention to the ladies' comforts, cheval mirrors are to be found in all the dressing-rooms.

Going up another flight of stairs we come to the studio, which is built in an L-shape, the long limb forming the principal studio, which is arranged to be worked at both ends, the short limb of the L forming a small studio with a slanting top front light.

The walls of the studio are covered with the lace oil-painted—same as the showroom—in this case the colour is a greenish old-gold tone. The shutters run in three grooves, as we previously described as being fitted in Mr. Scott's studio, but in Mr. Warneuke's case they are made ornamental by each of them having a pattern and forming a panel. The top blinds are arranged and fitted on metal rollers—guide cords are dispensed with—and by a simple draw a ten-foot blind can be arranged with great ease.

The new American background stands are fitted, one at each end of the studio. Alongside is the Morgan's new vignetting ground and stand; here and there in the studio stand old antique oak cabinets, filled with bric-à-brac ornaments. The other general furnishings and fittings having been carefully thought out and arranged has resulted in so perfect a room, that Mr. Warneuke might be well proud of it.

The apparatus for electric lighting has been conducted into the studio, and stands ready for connexion. He has arranged to get his supply from the Corporation main—it will be some little time before they supply—but, when ready, he has contracted for light equal to 30,000 candle power; quite irrespective of taking pictures, his whole place is to be lighted by electricity.

The printing premises are at the back of the building, and entered from Wellington-street. Collodio-chloride pictures are what Mr. Warneuke favours most, and the tone he prefers and produces is a rich, reddy-brown, very charming to look upon, and which have caught on to the public taste; a taste that is often slow to catch even with the most artistic productions. The large platinum pictures that Mr. Warneuke has been sending out to most exhibitions have made way for him, and extended his popularity and name far beyond local limits. Being no stay-at-home-worker, medals come from all parts, both home awards and from across the seas.

SOMETHING ABOUT SHUTTERS.

The introduction of the new Jena glass lenses, with their flat field of definition at large apertures, changes certain conditions of exposure where it is of brief duration or so-called "instantaneous." Hitherto we have been satisfied with the central shutter in the case of compound lenses, because what was lost in the time required to open and shut was compensated for by the better definition caused by the exposure beginning with a point and ending with the same.

But a radical and insuperable difficulty in this form of shutter is that, during the entire duration of the open and shut action, any movement in the subject affects the impression; and, as this action is a double one, and the exposure is less than the half of that which

would be given by the same lens with the full aperture, being, in fact, only that of an aperture which has the quarter (approximatively) of the full area of the aperture employed, any approach to a minimum exposure is out of the question.

A shutter which operates in the mid-lens position, and does not open in the centre and close there, interferes with the perfect focussing of the image, as any one may see by focussing with the aperture of a rotary diaphragm partially, *i.e.*, eccentrically, placed, half way revolved into its proper position. There is a certain correction in the result, as the opening in the passage from one side to the other commits the same error in both directions, and the effect is only a slight confusion of the image, not enough to be noticed under ordinary circumstances.

The action of a shutter which presents an aperture passing from side to side when placed between the lenses is, therefore, objectionable in theory, and of no advantage in practice That of the form which we may call the guillotine, *i.e.*, in which a slot passes from top to bottom, or the reverse, or from side to side, is not correct, therefore, in the central position. But, if we apply the same action in the case of an exterior shutter, whether placed behind or before the combination, there is an entirely different effect. We do not diminish the illumination of any part of the field, but give the full power of the lens to each part of it, passing rapidly from side to side, with no return, so that we get all the light that is given, which permits each part of the sensitive film to be given a minimum exposure in as rapid succession as may be desired, and no interference with the definition is caused, either for the better or the worse; we simply uncover and cover again, by a progressive movement, the field of view, as it would be seen from the position of the sensitive plate. This is the action of the admirable, and once famous, pantascopic camera of Mr. J. R. Johnson.

With the old form of rapid lenses, whether symmetrical, rectilinear, anti-aplanatic, or other, in which the field of definition was curved, such a shutter gives no compensation for the interference with the equality of illumination by the proportional sharpening of the ray during the greater part of the exposure, and consequent better definition. The introduction of the lenses with a plane field of definition leaves nothing to be gained on that side; for the whole field is in focus on any given plane, and the loss of focus from plane to plane is at a minimum. What is wanted with these lenses is, then, a shutter which goes before or behind the combination, with an opening passing from side to side. The drop shutter is correct in principle, so far as the nature of the exposure is concerned; but it errs in giving the succession from bottom to top, or the reverse, because the motion, which possibly interferes with perfect definition, takes place from side to side (except in the case of falling objects), and the head of a figure passing through the field would therefore be taken before its feet, and, however slight the interval, the figure would be, *pro tanto*, distorted.

Where the time of exposure is largely in excess of that of the action of the shutter—*i.e.*, where the shutter works rapidly and remains open for an appreciable time, as in most landscape work—the central-opening shutter, whether before the combination or between its parts, presents no material objection; but in the former case, in what is called instantaneous action, it exaggerates the central illumination, and in both cases it diminishes the effective exposure as indicated by the time of the action of the shutter.

W. J. Stillman.

AMERICAN WORK AND WORKERS.

[Birmingham Photographic Society.]

In speaking on a similar subject before the recent Edinburgh Convention, I could only venture on a very general treatment of it, so that when your kind invitation to address you was received I decided to speak further on what camera workers are doing in the United States. We draw the lines quite as sharply as in Europe, and have as various species of the genus "crank"; but, after all, little really progressive work is ever accomplished in the world without the workers being looked upon as mentally unbalanced, to state it mildly, by those not possessed of a like enthusiasm. The devotees of the camera must bear their share of this experience, for, in spite of all proof to the contrary, the uninitiated are still unwilling to believe that the results of photography are not due to luck or, at best, a cleverly managed trick. We can well afford to smile at this view, however, realising, as every genuine worker does, the higher position it is constantly assuming among the world's actively beneficent forces.

Hand Cameras versus Stand Cameras.

With us, as more than once stated, the camera is too often considered only as a means to kill time, and the fact is then lost sight of that the so-called snap-shotters possess in their ever-ready instrument a wonderful, though too-often abused, power. But they should not claim for it perfect equality with tripod work. My own preference for the latter is mainly that, as more care is usually given to it, the results are better than hand work, but it seems also as if the former admitted of greater latitude in composition, to say nothing of subsequent treatment of the negative (which when well done is perfectly legitimate, from an artistic standpoint), and—I say it advisedly—the greater choice as to selection of subject it places in the worker's hands. This is without detracting from the use of hand cameras, which form a department of their own, covering an important field, and which should not necessarily conflict with tripod work. In the hands of any one who has gained large experience with the tripod, the hand camera is a valuable power, but with us the latter is usually considered as being easier to manage than the former, is therefore preferred by beginners, and its results cannot justly be compared with stand-exposures.

There is a very amusing amount of ignorance in the land on the subject of shutter-exposures, and the idea seems prevalent that instantaneous work (I dislike the term) is the result of some occult power residing in, and solely due to, the instrument, having nothing whatever to do with the operator. I was asked lately, on the shore of Loch Katrine, where my 8 × 10 tripod camera was being used. "Does your camera take instantaneous pictures?" "That depends on how you use it," was my reply, which seemed to puzzle my interlocutor. With us, as well as here, the camera army is divided into what might be termed "tripods" and "anti-tripods;" but we seldom use one to the exclusion of the other, except among those who do little, if any, really serious work. As long as the average user of a camera is satisfied with playing at photography, he will never consider it is worthy special respect. It should be stated in strict justice that, as a whole, American clubs offer finer working facilities than those of any other country, and are imbued with a progressive spirit which readily embraces every new improvement. Americans are—and I claim it without undue self-praise—not only able, but willing to learn where they make up their minds the game is worth the candle, and a really good idea is certain sooner or later to find general support. We do not hold on to any method or opinion because of proper respect for age, or welcome it because it is young.

One point which to my knowledge has never been considered is that camerists have widely differing gifts in the photographic field. Some do best in the studio, some with architectural subjects, such as interiors, and others with hand cameras. Very few can or should undertake to do all these with hope of equal success. I think one fault with us is that we are apt to attempt this all but impossible task.

American Apparatus.

Let me emphasise one point in favour of American methods, or, rather, instruments, which is to some extent being introduced in England—the question of lighter plate-holders. Englishmen claim that with them bulk is as great a consideration as weight, but to me the point does not seem to be well taken. Our holders may not be as ornamental in appearance as the smoothly polished ones so general here, but they serve the purpose of keeping out light just as well, and the slides are not nearly so inconvenient as the permanent ones which project beyond the camera, and at any moment are liable to cause vibration or to be broken off by a sudden movement of the operator. I must also endorse having the word "exposed" printed on one side of the slide, which, if the operator takes care to replace correctly, positively prevents double exposure. Their use, like most of the other mechanical appliances, requires a certain amount of brains, otherwise common sense. The tripod I am now using, and have for several years, is easily and quickly adjusted, and packs into a small compass, as does the camera, which closes in on itself, thus protecting the lens if a wide angle one, and the hinged ground glass is discarded in favour of one which permits being held back so as to let the plate-holder take its place, and when the holder is withdrawn the glass slips back into position. The tendency is growing to have as few projecting screws or other parts as possible, and those recently made are particularly noticeable in this respect. Opinions differ as to the advantages of front or back focus, being slightly in favour of the former except in the studio and with enlarging or reducing work. Few, if any, of our cameras are made to have the tripod top permanent in the instrument, but it does save room, and the idea is therefore good. We are in serious danger of making our instruments, especially the cheaper grades, altogether too light; but the demand is for portability combined with cheapness, and this leads to an enormous sale of small-size instruments. I have one camera in my large collection which cost hardly twelve dollars—camera, tripod, plate-holder, lens, and carrying case complete, and it does very tolerable work. For some inscrutable reason the small prints in our exhibitions are called the English size, though I noticed in the various excursions at Edinburgh very few

even whole-plate cameras. With you, as with us, the reason is usually given that enlargements are always available, but my preference is always for direct prints.

Uniform Sizes of Plates.

It would seem to be a fitting matter for international arrangement, the coming to some agreement for uniform sizes of plates. Our favourite size, notably for hand cameras, is 4×5; 5×7 has superseded 5×8 as giving a better proportioned picture, and from thence we go through 8×10, 11×14, up to as high as 18×22, but even the most ambitious seldom venture beyond 8×10. Before we made such excellent cameras we were dependent on foreign makers, and those of us who were not natural mathematicians were often annoyed by what we considered inconvenient numbers, those with fractional additions. The reason given us for retaining these latter has been that the glass thus cuts to better advantage, but I fail to see why it is not possible in the first place to make the sheet of glass of such dimensions as to cut evenly into any size plates desired. I have found it difficult to get 5×7 plates in England, though not 8×10.

Lantern Exhibitions.

We are taking great interest in lantern exhibitions, and it is an encouraging sign of comradeship that so many sets are being exchanged between English and American workers. If each, however, will insist on retaining a different size plate, the carriers, at least, should be international, so as to hold either size conveniently. We are, to some extent, using the arc light at these exhibitions, as well as for enlarging, and making slides, but it is so much more powerful than the oxyhydrogen, that the slides should be made with that point understood, or they will show weak on the screen. Our manufacturers make excellent negative and lantern plates, and I have been taken to task more than once this summer for saying ours are more rapid than the English, often a very questionable advantage, but actual experiment has proved to me that, with two representative makes of lantern plates, I had, under precisely similar circumstances, to give the English three times the exposure of the American to gain the same result. We are giving increasing attention to the nature of the subject in matting and mounting our slides, and the old circular, or even uniformly round-cornered matts, are now seldom seen. I must mention that in one of the New York societies the slides are thrown from behind on the screen, which is transparent, giving a charming ground-glass effect. One amateur, having a private lantern, projects his slides on a heavy ground glass, placed between two parlours, and framed by curtains. The effect is excellent. With my own oxyhydrogen apparatus, I use a heavy linen screen, buttoned on a framework, like an old-fashioned quilting frame, set on rollers. This is thoroughly wet, and then stretched taut. The light is powerful, and every slide I send out is thus tested before mounting. My matts are all cut from special designs, and sometimes a dozen will be tried on one slide, and the same slipped into my lanternoscope for examination before a choice is made. We have what are called test nights in two of the New York societies, when one or more of the Lantern Committee attends to give a final decision before the slide is considered suitable for a general audience, though the meeting is very informal, and members feel perfectly free to express individual opinions to the pleasure or otherwise of the respective slide-makers. In one society, if desired by any member, the meeting-room is at his or her disposal for an entertainment, and one of the Lantern Committee will attend to manage the slides. Films, in place of glass, seem to make their way slowly among us, in spite of their undeniable merit of lightness, and I can speak feelingly on the subject, considering the quantity of 8×10 plates I have to carry home in October.

Films have certain defects which make me, as yet, prefer glass, but demand always creates supply, and I expect to see them eventually almost supersede the latter. One of our leading firms making photogravures urges me to copy all my valuable negatives on celluloid, as a precaution in case of injury to the originals.

The idea is good one, as experience showed, when one of my 14×17 negatives was smashed on its way back to me from the reproducers through careless packing. He made me a negative, original size, from the small transparency he used, but the qualities of the original would have been far better preserved by the method above mentioned.

Development.

Coming to the question of development, there is much divergence among ourselves, and what little developing I have done in England has shown me that this is especially marked when compared with English methods. We are not given to using ten per cent. solutions, as is much done here, for many of our workers are skilful chemists, and have a great liking for experimental work both in development and printing, studying the scientific theory as well as practice, some workers having fitted up laboratory attachments to their developing rooms. I must say, though, that it is not always those who have the greatest number of well filled shelves and shining weights who actually accomplish the best scientific results.

The use of acid-sulphite is quite general, and, though in club dark rooms the hypo solution is ordinarily kept in stock, home workers prefer to make it up fresh, graduating its strength as desired. My own custom is to partly fill my fixing dish with water, and then put in a handful or more, as judgment dictates, of hypo crystals and a little acid sulphite to keep the bath clear. Even then I do like to dip the negatives or lantern slides in a bath of saturated alum and sulphuric acid either before or after fixation. When pyro, which is still first with a large majority of our workers, is used with ammonia or soda, it has for a long time been my custom, many times suggested to others, to make up solutions of sulphite and carbonate of soda in large quantities by hydrometer measurement instead of weight, the pyro being always made up fresh one to twelve, and old developer never being kept under any circumstances.

Then, with a little, very little, saturated bromide of potassium, not ammonium, and plenty of water, the operator usually has only himself to blame for failure. It seems a little strange that English workers prefer ammonia to soda as an alkali, and Mr. Bothamley, in his Edinburgh paper, gave a very clear idea of the action of each, which, to my mind, seemed rather in favour of soda. I was asked in London, by a scientific expert, which side of photography was my "particular vanity," as Sam Weller would say, and on my describing the advantages of my developing room, was triumphantly told that such was practically acknowledging photography science, not art, a dictum to which I promptly and positively demurred, claiming that each has its own special standing, alike worthy, thereby proving the length and breadth of the photographic field.

Printing Surfaces.

We are turning more and more towards matt surface prints, largely platinum and kindred processes such as kallitype No. 2., and plain salted paper; but we make a great number of bromides, especially in sepia tones, which are considered a refreshing change.

The Manhattan paper admits of several tones, according to development, and Iota prints, also made on celluloid as transparencies, are likewise very effective.

These latter processes are quite slow. The paper sent out by the Eastman Company seems to fulfil the promises made for it, and can be utilised for either glossy or matt-surface prints. It is to be hoped that our workers will, after a while, give carbon printing the place it should occupy among us. We admit its beauty, but only a few use it, though an effort is being made now to encourage amateurs to try it. Two or three of our leading manufacturers are making the tissue, but the heat of our summers renders its use mostly confined to the winters, when the light is poor.

We trust that every year we, the two English-speaking nations, will grow into closer accord, and each learn from the other of its best characteristics. There should be only a healthy spirit of rivalry, enough to bring out the latent energies of each nation, and thus continually advance the work in which we are mutually interested. It is growing rapidly among us, constant improvements are being made, new apparatus and methods of work new invented, societies formed and, besides the regular photographic journals, the daily press gives space to all especially interesting meetings, and our purely literary magazines more and more are utilising the art-science in their pages, for illustration and in the shape of articles. Photography has a great future among us, and he would be indeed a prophet who could reveal it; but we never will make lasting and steady progress without keeping thoroughly informed on the work being done this side of the ocean. We should mutually take part in each other's exhibitions, and can in no better way realise our deficiencies and gain courage from our evidences of progress.

There is plenty of room in the world for good work, and such will surely meet with recognition in the end. We, in common with our English co-workers, should steadily hold that fact in view, and give our best energies to its accomplishment. Thus, and only thus, do we deserve to reap the fruit of our labours in the many-sided harvest of photography.

Catharine Weed Barnes.

ROYAL CORNWALL POLYTECHNIC EXHIBITION.—PHOTOGRAPHIC DEPARTMENT.

Report of the Judges.—Professional Section.

The Judges have the pleasure to report that this department is well sustained both in the professional and amateur sections, and they were pleased to notice that upon no previous occasion was there less work of an inferior character. The first name which appears in the catalogue is that

of Mr. W. H. Harrison, a local photographer, who shows in several classes, and a first bronze medal is awarded to him for an enlargement of *Penryn street.* Mr. Whaley, of Doncaster, is represented by a picture of the *genre* order. Mr. Robert Frost, of Loughborough, two frames, one of which contains an amusing picture of *Missus' New Bonnet.* Mr. W. Scorer, of Havant, has three very large pictures taken on 30 × 24 plates, two of which would have been much improved by the addition of clouds. To his large view of Portsmouth Town Hall has been awarded a first bronze medal. Mr. W. J. Byrne, of Richmond, Surrey, takes a second silver medal for *Portrait Study of a Lady*, and he also shows several other works, including *The Alphabet Illustrated.* Messrs. Chaffin & Sons, of Yeovil, exhibit several frames of large portraits. Mr. Lyd Sawyer, of Newcastle-on-Tyne, this year has taken a new line with his *genre* pictures. Mr. R. H. Lord, of Cambridge, takes first silver medal in the *genre* class for his fine picture named *How's That.* Mr. J. Edison has one frame of indoor studies. Mr. R. Yeo, of Plymouth, is well represented. Mr. A. Guye sends a frame of fine enamels which have secured hon. mention. Mr. J. Milman Brown, of the Isle of Wight, receives a first bronze medal for *Landscape with Sheep*, and he shows several other very creditable productions. Mr. E. Vigo, of Chelsea, has sent several enlargements, which are somewhat hard and cold in tone. Mr. P. Lewis shows a frame of little gems, *Seaside Studies*, hand-camera work. Mr. Thomas Protheroe, of Bath, has taken first bronze medal for a portrait enlargement. Mr. W. J. Anckorn, of Arbroath, has been awarded a second bronze medal for flower study, *Lilium auratum.* Mr. C. James shows a well-posed group called *At the Pantomime.* Mr. C. A. Brightman exhibits some good interior work of Gloucester Cathedral. Mr. R. Terras has some *genre* pictures which evince careful study. Mr. Ernest Spencer shows four portrait studies, printed in platinum, which are very effective. Mr. Adam Diston has several pictures of the *genre* order in his well known style. Mr. R. S. Webster, of Edinburgh, sends an enlargement of a landscape showing castle. Mr. Wheeler exhibits a panoramic picture, printed in sections, of *Glaciers, South Island of New Zealand.* First silver medal for portrait work has been awarded to Mr. William Warneuke, of Glasgow. His work is of a very high order, and his landscapes deserve special commendation. Mrs. A. E. Blake contributes some portraits finished in colours by the air-brush process. Mr. Norman Blake sends three studies of flowers.

Amateur Section.

Rev. A. H. Malan shows a frame of curious pictures of the instantaneous order representing the last of the broad gauge. Mr. A. L. Spiller shows a frame of nine specimens of ancient armour, which are full of detail. Mr. J. F. Lloyd, of Liverpool, shows four frames of cloud, marine, and rural studies, which show very careful work. Rev. J. E. Hermon has a series of pictures of Venice of great interest. Mr. A. W. Gotflieb exhibits a good number of works, the most striking of which is a study of a bunch of grapes—it is almost stereoscopic; it receives a second bronze medal. Mr. J. Campbell shows four marine pictures. Rev. H. B. Hare, of Frome, is represented by three pictures in his well-known style. Mr. H. Tonkin, of Penzance, receives a second silver medal for his enlargement, *A Land's End Fisherman*, which is undoubtedly well merited; he also shows many other excellent specimens. Mr. A. R. Dresser, of Bexley Heath, exhibits enlargements printed on rough drawing-paper. Mr. C. A. Roe has been awarded first bronze medal for his picture, *The Sedge Gatherers*, and his other productions are very artistic.

Messrs. Brightman, Stabb, Harding, and Major J. D. Lysaght compete in the Hand-Camera class, the latter gentleman securing first bronze medal for his well-executed examples. Mr. F. H. Pickford sends a picture of a rather sensational order, of *Miners at Lunch*, taken 1120 feet below the surface in a coal mine, "Talk-o'-the-Hill," Hart's flash-lamps being used, same as exhibited a few years since. Mr. J. E. Austen sends some clever little pictures. Mr. K. E. Truscott shows several miscellaneous examples. Mr. H. Dudley receives first bronze medal for *An Old Porch*, which is well rendered. Miss Amy F. Eales sends three views near Penzance. Mr. A. J. Leeson has two editions of *A Thirsty Crew.* Mr. C. B. Moore, of Philadelphia, sends several pretty studies. Mr. W. L. Colls contributes four pictures, his river studies being very artistic. Mr. J. W. Evans sends three photographs of *Street Arabs.* Mr. A. Nicholson receives first bronze medal for instantaneous work *Off to the Fishing Grounds*; he has also some fine *Interiors of Haddon Hall.* Mr. A. G. Tagliaferro has three pictures of the *genre* order of an amusing character, to which honourable mention has been awarded.

Photographic Appliance Section.

Mr. W. Newton, of Fleet-street, London, sends two portable tripod stands, fitted with Elmer's patent levelling head, made in platinum, which is a very clever arrangement, and commends itself to travellers; he also sends a telescopic tripod stand, in the same metal, which is very light and portable. Mr. Hawkins, of Bloomsbury, London, sends a magazine hand camera, which possesses many novel points; it is well made and very simple in its construction and easy to work; the shutter is a very clever arrangement. Mr. H. Smith sends an adjustable printing frame for vignettes, which is very effective.

During the Exhibition week Mr. W. Brooks gave two lantern entertainments to large and appreciative audiences, Mr. J. F. Peasgood being the lecturer.

PHOTOGRAPHIC INDUSTRIES.

Messrs. Elliott & Son's Works at Barnet.

Since last we had occasion to inspect Messrs. Elliott's Works at High Barnet, considerable changes, not only in the scope but in the personnel of the house, have taken place. Whereas formerly the style of the firm was Elliott & Fry, which indicated that the establishment at Barnet was devoted to the production of the printing and enlarging for the famous Baker-street Portrait Studio, it will have been observed that the name has recently been changed to that of Elliott & Son. This alteration emphasises the fact that the house of Elliott & Son has been entirely dissociated from the firm of Elliott & Fry, with which, indeed, at the present moment its relations are simply those of any other business house, the two firms being entirely distinct in all respects. The erection of the house of Elliott & Son into a separate concern has led to some additions to its field of operations, the chief of its new undertakings being, as our readers are of course aware, the manufacture of the now well-known brand of "Barnet" dry plates.

Within the last few days we were given the opportunity of visiting the works at Barnet in order that we might observe the degree of expansion they had undergone since the date of our previous visit. On this occasion our conductors were Mr. Hubert J. Elliott, the son of the principal, and Mr. Birt Acres, the manager, the former gentleman exercising, we gathered, personal superintendence over the department devoted to the preparation of the dry plates. It should be here remarked that, for the innumerable photographic purposes to which these works are devoted, scarcely a better situation could be desired, their position at the summit of a lofty hill, and commanding a north-eastern aspect over open country, being an eminently agreeable and suitable one.

Possibly in few similar establishments to Messrs. Elliott's are there so many departments in simultaneous operation, and so large a number of rooms set aside for their due and proper conduct. Indeed, when we were there, the rooms we passed through were so numerous that we found it difficult to keep count of them, while their description, or even their mere enumeration here, would occupy a more considerable portion of space than could be well spared. Naturally, the dry-plate department first claimed our attention, and after passing through the glass-cleaning room, where we observed that the glass was being cleaned by the homely device of scrubbing, we came to the coating room, which is partly situated underground, and the temperature of which is controlled without the use of ice. Cadett's highly ingenious coating machine is used, its rapidity of working allowing of thirty-three half-plates per minute being coated. Here we note that at Barnet, in contradistinction to several other dry-plate factories, the single, instead of the double, half-plate is coated, Messrs. Elliott making it a feature to cut as few of the coated plates themselves as possible. The coating room is illumined by orange-yellow light, though the plates, as they leave the machine, are examined by ruby light, which, Mr. Acres informed us, is essential for the detection of defects. The washing, cooking, and drying rooms, all fitted with the most recent appliances, were in turn passed through, and incidentally we learned from Mr. Acres that the Barnet plates are tested stereoscopically—that is, a newly made plate, and a standard plate of known quality receive equalised exposure and development, in order that comparison may be the more readily and assuredly obtained. The stores departments of this section of the establishment amply attest the large output of plates.

If only for the extensive amount of silver printing which is executed there, it would be quite worth Messrs. Elliott's while to sensitise their own paper, but, when to this home consumption is added a large sale, it will be understood that this department, through which we were shown, is an important one. Pausing for a moment in the room where the fixing and washing are conducted (the latter being performed by the passage of the print through several successive baths), Mr. Acres stated that, during the recent epidemic of blisters, these scourges of the silver printer were unknown at the Barnet Works. Carbon printing and enlargements are a speciality of Messrs. Elliott, and at Barnet the carbon process is, as we said, worked *ab initio*, even the tissue, treated with something like twenty varieties of differently coloured pigments, being prepared there. We were shown a number of fine carbon enlargements recently executed. Two of these (one from a negative of a dog by Mr. Fall, the other a sea-piece of Mr. Birt Acres) were on view at the Edinburgh Convention, and attracted much attention. Besides one devoted to bromide enlarging, a separate department is occupied by platinotype printing, which is here largely employed. A great deal of the printing is done out of doors on shaded benches readily movable to any position, and at the time of our visit some hundreds of frames of various sizes were in requisition.

To a large extent a trade printer's or enlarger's partakes of the nature of a photographic hospital, for hither come all sorts of cripples in the way of

negatives, from which good enlargements or prints must be got by hook or by crook. We were struck with the skill of Messrs. Elliott's staff in the art of doctoring poor negatives, and of making excellent enlargements from indifferent originals. Mention of enlargements reminds us that for enlarged negatives the wet-plate process is employed at Barnet, and we were highly delighted with the extensive and, at the same time, extremely able manner in which the process was being worked while we were there. The wet-plate room appeared to us a model of neatness and good order. Daylight and artificial light are employed as occasion allows, the maximum size of negative made being 53 × 38. The silver bath for this and smaller sizes is swung on its centre, thus assuring an even flow to the solution. An adjacent room is devoted to the glass-cleaning.

An immense number of the small carbon opals with which the public are familiar are produced at the Barnet Works, quite a staff of young ladies being exclusively occupied in touching out defects, a huge pile awaiting their good offices as we passed through this department to that in which other young ladies were engaged in like attentions to silver prints, and thence to the domain of the artists whose duty it is to work up and finish off bromide enlargements, &c. Other rooms contained stores of negatives, mounted prints, and cards, a separate room being occupied for mounting. Needless to say, that in the course of our peregrinations the heating, ventilating, and machinery-driving arrangements were duly shown and explained to us, and, like everything else at the Barnet Works, appeared to be of the newest and most effective type.

The foregoing brief outline may convey some idea to our readers of the ramifications of Messrs. Elliott's business, although, as a mere effort of description, its inadequacy must be apparent when we mention that it took us several hours, in company with our courteous *ciceroni*, to traverse the innumerable rooms of the establishment. This very inadequacy can but, however, serve to indicate the extent and importance of Messrs. Elliott's Barnet Works, to which we have no hesitation in assigning a high place among modern photographic enterprises.

Our Editorial Table.

The Year-Book of the *Fotografisk Tidskrift* (our Stockholm contemporary) has a number of able articles and serviceable formulæ. The illustrations, of which numerous examples of the chief processes are given, are some of the finest we have seen in a photographic publication.

The Dallastype Shakespeare. Part II.

Duncan C. Dallas, 5, Furnival-street.

The second number of this reproduction of the First Folio (1623) edition is before us. It gives the chief part of the play of *The Tempest* in "Dallastype," which compares most favourably with other reproduction processes previously employed on the famous edition.

From Messrs. York & Son we have received their twenty-third annual supplemental catalogue of lantern slides and lecture sets for 1892–3—which gives particulars of many recent and attractive additions to their lecture sets, topographical, fictional, and otherwise—one being devoted to the life and works of the late Mr. C. H. Spurgeon. We note that the firm has removed to larger premises at 67, Lancaster-road, Notting Hill, W.

Messrs. G. W. Wilson & Co.'s list also contains particulars of many new sets from negatives by G. E. Thompson (Norman, Italian, Dutch, &c.), Lyddel Sawyer (*genre* studies), and other clever photographers. With few exceptions, the whole of these new sets are from direct negatives.

Pictorial Selection in Photography. By W. D. G.

Photographic Section of the Croydon Microscopical Society.

This admirable paper on composition as applied to picture-making by photography has now been reprinted, together with the excellent explanatory illustrations, in pamphlet form. As an enunciation of the rules of art which should govern the selection of photographs, it is distinguished by such clearness and accuracy as to be easily comprehended by students of photographic art. Copies of the pamphlet, which is tastefully printed, may be obtained, price *7d.*, of Mr. H. D. Gower, 16, Wandle-road, Croydon.

Standard Lens Flanges and Adapters.

By Taylor, Taylor, & Hobson, Leicester.

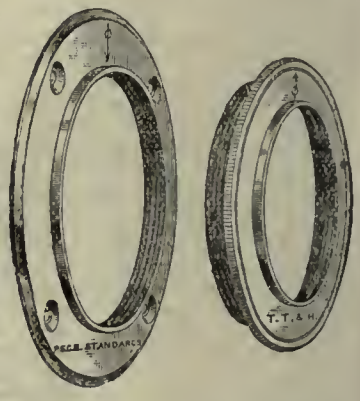
We have very often commented on that serious absurdity and drawback in our lens system, the infinite variety of diameters and screw-threads adopted in the lenses and flanges of the various makers, both at home and abroad, similar lenses of one manufacturer not screwing into the flanges of those of another producer. The Photographic Society of Great Britain did a great work in recommending a definite standard for adoption, and it is much to be regretted that this is not yet generally adopted, although it has been so in some instances. We have often cited the case of the microscope, in which uniformity prevails throughout, as the system which ought to be adopted with photographic lenses. We hail with pleasure every effort made to bring about this state of affairs; and as a very lucid exposition of certain improvements in this direction made by Messrs. Taylor, Taylor, & Hobson, we make no apology for printing the following which we have received from them:—

"We have much pleasure in sending you, by post, a 2-inch standard lens flange, and a 2 to 1·5-inch standard adapter, as examples of our recent improvements in lens fittings.

The well-known difficulty of starting the usual form of screw has two elements—that of knowing at what point in the revolution the threads first engage, and the difficulty of holding the screws in correct relation axially. Our invention surmounts these two elements of difficulty.

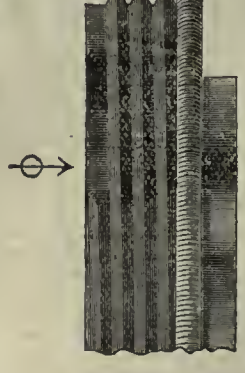
In order to describe it fully, it is necessary to refer to the system we designed for providing that all lenses fitting the same flange are held with their diaphragm indexes or other fittings in one uniform convenient position. The present invention is a supplement of that system.

By arranging that the threads of male flange screws upon lens mounts should terminate at their shoulders in one uniform position in relation to the diaphragm indexes, it was provided that they might all screw home with their diaphragm indexes in one convenient position. In the present invention, by arranging that the threads commence abruptly in a similar uniform position in both male and female screws, it is provided that any lens, when presented to its flange with its diaphragm index uppermost, or as it is arranged to be used, is in position, on being turned, to at once engage with the screw of the flange.



The illustrations show a standard flange and an adapter in the position of rotation at which the screws would immediately engage on being turned. This position is shown by the zero marks, which would again coincide when the flange and adapter have been screwed together. In the same way, any properly constructed lens would screw into the flange or adapter, its diaphragm index being at zero at the commencement and completion of the engagement.

So far it has been shown how this invention decides at what part of their revolution the screws shall first engage. The enlarged portion of a standard adapter seen in the illustration exhibits the manner of forming the male screw thread to commence abruptly near the zero, and it will be understood that both the internal and external screws are formed similarly in this respect.



The common practice of merely chamfering or bevelling the ends of screws, which leaves the threads to terminate not abruptly, but to die away gradually in the course of revolution, not only makes it difficult to find the position for first engagement of the screws, but by forming the chamfers into a kind of ball and socket, makes it hard to determine their correct position axially.

It will be seen that our method of removing this usually incomplete portion of a thread, and forming a cylinder at its root, provides a clear shoulder and bearing which determine the true axial relation of screws when placed together for engagement.

For convenience and uniformity the zero of a screw and its abrupt commencement are at that part of the revolution at which the point of a tool cutting the female screw would lie in the plane of its face or shoulder.

It must be borne in mind, however, that this applies only to a screw of absolutely correct size and form, for any error in the dimensions of a screw would cause corresponding displacement of its true zero.

For some time past, in view of the importance of accuracy in these matters, we have given attention toward the improvemsnt of appliances

for making and measuring screws, with the result that we now prepare all screwed fittings within a limit of error of one-thousandth part of an inch on their diameter, and confine the error on that side of the normal which ensures perfect and free interchangeability.

The fittings we have pleasure to send you as examples of our improvements in screws have been prepared to this degree of accuracy, and, with allowance for some very slight alteration during the processes of finishing, we are confident that all work leaving our factory is thus accurately formed."

We have nothing to add to this further than to say that the specimen flange and adapter received attest the great accuracy achieved in the fitting.

Spotting and Colouring Media.

J. R. Gotz, 19, Buckingham-street, Strand.

Mr. J. R. Gotz has submitted to us specimens of a new kind of moist colours for colouring photographs, which are applicable either to albumen or gelatine-surfaced prints. A special feature of the colours (of which there is a great variety) is that they dry with the same degree of gloss as the surface of the print. Mr. Gotz also has a series of moist "spotting" colours useful for either touching out defects on negatives or positives without previous preparation of the surfaces. Both sets should be extremely useful to professional and amateur alike.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
September 5	Dundee Amateur	Asso. Studio, Nethergate, Dundee.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

August 25.—Mr. J. J. Briginshaw in the chair.

Mr. Hubert J. Elliott was elected a member of the Association.

Messrs. Sprange & Co. sent a sample of sensitised paper (about quarter-plate size) for exhibition among the members; while Messrs. Newman & Guardia sent circulars of their "N. and G." shutters.

Stereoscopic Photography.

In the course of the adjourned discussion on this subject, a brief conversation on pseudo-scopic effect took place, subsequent to which Mr. T. Bolas alluded in complimentary terms to Dr. Donnaden's recently published book on *Stereoscopic Photography*.

Mr. J. S. Teape said he preferred to look at pictures without a stereoscope, as a great many stereoscopic pictures caused him much more pain than pleasure, which was the case with several pictures exhibited before the Association about eighteen months ago by Mr. A. L. Henderson. Several of these would not combine, and caused him such pain that it was impossible for him to continue looking at a number of pictures. He fancied that the principal cause of this was the incorrect mounting.

Mr. W. E. Debenham remarked that, by moving the lenses, the pictures Mr. Teape complained of would probably combine.

Mr. Teape (continuing) alluded to a collection of stereoscopic slides he had brought with him, and said that they exhibited two kinds of distortion—in one case one picture being mounted higher than the other. The slides were between thirty and forty years old, and had been placed for eight years in a damp cupboard, where some of them had got stuck together and mildewed. Only a few, however, had deteriorated. In one slide both pictures were exactly alike, so that no stereoscopic effect could be obtained.

Mr. J. Weir Brown said that one fault with stereoscopic slides was that they sometimes showed more stereoscopic effect than was agreeable to the eye. They were, in fact, something like the set scenes in a theatre—one part standing out very much like side pieces.

Mr. Debenham asked whether the slides to which Mr. Weir Brown referred were from nature? If the lenses were separated more than the natural distance of the eyes, the effect of a model would be obtained. No photograph from nature would give that effect. An object looking like a set scene at a theatre would have greater rotundity, and would, in fact, be like a miniature model with everything in its own proper relief. He thought they were justified in using instrumental aid for obtaining more relief than with the natural eye.

Mr. Bolas spoke of a photograph of the *Venus of Milo*, which, owing to a wide separation of the lenses, showed an exaggerated relief when viewed in the stereoscope.

Egg Albumen *versus* Blood Albumen.

The following question from the box was read: "How can photographers tell whether blood or egg albumen has been used in the preparation of sensitive albumen paper?"

Mr. Bolas said he had had submitted to him samples of blood albumen which showed signs of putrefaction, while others did not. He thought it was rather a question as to how the albumen was treated than the origin of it.

The question was not otherwise answered.

Flower Photography.

Mr. Weir Brown asked what was the best background to photograph a white flower against, at the same time passing round a photograph of a white flower backed up with black velvet, against which some green leaves were indistinctly rendered.

Mr. Beckett recommended brown paper placed out of focus.

Mr. C. H. Cooke would use a grey background with a plate dipped in erythrosine.

Amidol.

Mr. J. A. Sinclair exhibited a number of lantern slides developed with amidol according to the following formula:—

Amidol	80 grains.
Sodium sulphite	800 ,,
Water	8 ounces.

For use, one ounce of the solution diluted with three ounces of water, with one and a half grains of potassium bromide to the ounce of developer.

The tones of the lantern slides were much admired, and Mr. Sinclair stated that he had used the developer for negatives successfully.

Hackney Photographic Society.—August 23, Mr. Hensler presiding.—Members' work shown from Messrs. A. Barker, Dean, Hensler, and Sodeau. Borax recommended to be added to toning bath for printing-out paper. Mr. R. Beckett read a useful paper on *The Suitable Printing Process for a Given Negative*, recommending the following: Bromide rapid paper, at great distance from the light for thin negatives; bromide slow paper, longer exposure, and thicker negatives. Bromides generally require a thin negative with a compressed scale of gradation. For enlarging, avoid hard or yellow negatives. The greater the distance the more latitude. Always make a test exposure. Contact printing—exposure must always be exact. Ferrous-oxalate developer—best half old, half fresh. Alpha paper—half tones must not be too heavy. Over or well expose, should develop red colour; can then tone all shades from red, brown, black, to blue. Developer recommended, hydroquinone and elkonogen mixed, can be used over and over again. To mount alpha paper with the polished surface, paste waterproof paper on back (black side outwards) after squeegeeing. Use glue and treacle, or glue and glycerine, work up to a froth on a board, hold print in hand, dab on and off several times in the same way that boxmakers do, till sufficiently glued, and place on card mount. Gelatino-chloride papers, same treatment. Platinotype, high lights must be heavy; use the new cold-bath process. With this paper the delicate tones do not fix out much. Carbon tissue, best for all work above whole-plate. Thick pigment for thin negatives, and vice *versâ*.

Leytonstone Camera Club.—August 24, Special General Meeting, Dr. W. Pickett Turner in the chair.—A proposal was brought forward from the Photographic Society of Great Britain, setting forth the advantages of affiliation with them. After a discussion, it was decided to become affiliated. The Exhibition was decided to be held on November 10, 11, and 12, at the Masonic Hall, Leytonstone.

Richmond Camera Club.—At an informal meeting held at the "Greyhound Hotel" on the 26th instant, the President in the chair, Mr. G. W. Ramsay brought some fine studies of sea and cloud taken from his yacht, and some printed on rough drawing-paper. Mr. Cembrano, junior, showed a copy of the Convention Group taken on a whole-plate by Mr. J. Stuart, of Glasgow, which showed remarkable definition and good detail, although taken with a drop shutter and lens of *f*/12·5; the lens used was one of Zeiss's, of seven and three-quarter inches focus. Mr. Ennis had a series of experiments on toning Ilford printing-out paper, showing a great variety of colour, from red-brown to black, the first colour being obtained by one minute's toning in a combined bath, and the black by a quarter of an hour's immersion in the same bath. He further exhibited a print on the same paper, which had been exposed to sunlight during the last six weeks, one-half of which had been covered with black paper; no deterioration or signs of fading were apparent. One of the members having asked which was the best way of stopping out pinholes in a negative, Mr. Cembrano said that he used smoke-black and a very finely pointed sable brush No. 0; instead of water, he preferred wetting the brush in his mouth; only the smallest amount of pigment was necessary, and, in order to match the colour of the negative, he would first try painting on the clear

rebate of it. Mr. C. H. Davis showed Ross's divided camera with swing-back attachment. Messrs. R. & J. Beck sent for inspection the Bynoe printing frame, which has the advantage of being small, casting no shadow on the print, and enabling the operator to have a full view of same. Mr. J. B. Huddy was elected a member.

Birmingham Photographic Society.—August 23.—The members assembled to welcome Miss C. W. Barnes, of New York. During the evening about fifty slides, comprising views of Birmingham, Warwick, Kenilworth, Stratford-on-Avon, Wooton-Wowan, Broom, &c., were exhibited by Mr. E. H. Jaques. Mr. E. C. Middleton described the different views as they appeared on the screen. Ordinary meeting held on August 25, Mr. G. F. Lyndon in the chair. —Three new members were elected. Reports were read of excursions to Berkswell, Wixford, Warwick, Aston, Cantlow, and Kenilworth. Miss Barnes accompanied the members on the latter excursion. Messrs. Marion & Co. sent a sample box of dry plates for the purpose of illustrating their new system of packing, the object of which is to secure a packing perfectly non-injurious to the film. The system met with the unanimous approval of the members present. The CHAIRMAN announced that the judge had awarded the prize offered in connexion with the Development Competition, held in July, to Mr. Geo. Wilkes. The enlargements offered by the Society for the best prints from negatives taken on the Berkswell and Wixford excursions were awarded to Mr. E. Underwood and Mr. Sears respectively. It was moved by Mr. E. H. JAQUES and seconded by Mr. E. C. Middleton: "That the hearty congratulations of the Society be offered to the President (Sir J. B. Stone) on the occasion of his receiving the honour of knighthood from the hands of Her Majesty the Queen." A discussion on *Hand Cameras and their Work* was opened by Mr. JAQUES. Messrs. GRIFFITHS, MIDDLETON, SHEAFF, T. TAYLOR, THOMASON, UNDERWOOD, and the CHAIRMAN took part in the discussion, which was of an extremely interesting and instructive character. Several hand cameras were exhibited and described. Miss C. W. BARNES then delivered her paper on *American Work and Workers* (see page 567).

Liverpool Amateur Photographic Association.—August 25, the President, Mr. W. Tomkinson, in the chair.—Messrs. E. T. Cockerham, A. S. Clare, A. A. Vos, and H. Anderson were elected members of the Association. Mr. Marriott showed some specimens of home-made ground glass, which, he explained, were produced by simply taking two spoiled negatives, placing a little fine sand and water between, and grinding them together for a short time. Mr. F. H. Elsby gave a demonstration on the use of the Society's enlarging and reducing camera. The President then demonstrated the development of under-exposed and over-exposed plates. Under the same conditions as to light, stop, and subject, he had exposed two plates, one for about one-twentieth of a second and the other about five seconds, and from each he now developed a very good negative. The Secretary exhibited Beck's new printing frame, which enables the whole of the print to be examined at once without fear of movement.

Northern Tasmanian Camera Club.—Third Annual Meeting. The President (Mr. R. L. Parker) occupied the chair.—The Secretary read his report, in which he stated that during the year the progress of the Club had been most satisfactory; the number of members on the roll had increased from thirty-six to forty-two. The monthly meetings had been fairly attended, especially those during the latter part of the year, and those at which the optical lantern formed an important feature. At some of the latter meetings a number of visitors, including ladies, had attended. The optical lantern had been in good demand during the year, the loaning of it to members being much appreciated by them. The journals subscribed to by the Club had been in good demand, many of the members being very regular in their application for them as a means of information and instruction. The returns of income and expenditure were given in the Treasurer's statement, and a credit balance was shown. At the conclusion of the reading of the Secretary's and Treasurer's report, office bearers for the ensuing year were balloted for. Competition for the three vacancies on the committee was very keen, there being eight candidates. Four were equal in the first ballot; a second was taken, and the following result was arrived at:—*President:* Mr. William Gibson, of Scone.—*Vice-Presidents:* Rev. A. H. Champion, Messrs. R. C. Kermode, and R. L. Parker.—*Committee:* Messrs. A. C. Bonner, F. Stewart, and J. Sparrow.—*Hon. Secretary and Treasurer:* Mr. F. Styant-Browne. Hearty votes of thanks were accorded to the retiring President (Mr. R. L. Parker) and to the Secretary (Mr. F. Styant-Browne) for their services during the past year. The members of the Camera Club have reason to be well satisfied with the growing prosperity of the Club, and it is expected that during the coming year this prosperity will still continue to grow and do good work in fostering artistic instincts and the love for the scientific and beautiful among its members, and still more spread the knowledge of the charming art science of photography.

PATENTS COMPLETED.

IMPROVEMENTS IN MAGIC LANTERNS.

No. 12,244. HERBERT CHARLES NEWTON, 3, Fleet-street, London, E.C. *August* 6, 1892.

THIS invention relates to biunial and triple lanterns, the discs of which are made to coincide on the screen.

In such lanterns, the front plates carrying the lenses are hinged so as to be capable of tilting to converge the rays upon the same spot of the screen, from whichever division of the biunial or triple lantern they are projected.

This tilting of the lenses has the effect of diverting the optical axis from the horizontal to an inclined plane, and a difficulty is thus introduced in connexion with the luminant, which is the object of my invention to obviate.

The tray carrying the luminant usually slides in grooves on the base of the lantern, so that the luminant can be moved backwards and forwards towards and away from the condenser along the line of the optical axis. But when the front carrying the lenses is titled, as above described, the motion is no longer in the line of the optical axis, and the value of the adjustment is thereby considerably diminished.

It is desirable, to obtain the best results, that the luminant should be maintained on the line of the optical axis, and be capable of travelling to and from the condenser without moving out of the optical axis, and to this end I carry the lamp on supports rigidly secured to the lantern front, which also carries the lenses, so that the lamp follows the tilting movement of the front plate, to maintain the luminant in the optical axis of the lenses.

The claim is:—In biunial and triple lanterns, the employment of supports for the luminant, rigidly connected with the hinged or movable front plates which carry the lenses, substantially as described, and for the purpose set forth.

A HAND OR DETECTIVE PHOTOGRAPHIC CAMERA.

No. 13,448. GEORGE FREDERICK FRAAS, 18, Portland-street, Stepney, London. *August* 6, 1892.

MY invention relates to improvements in photographic hand or detective cameras, by which a number of sensitive plates or films may be successively exposed in a simple manner.

In carrying out my invention, I provide a suitable box, to carry two stages provided with springs or catches to hold the ends of the plate or film-holders when drawn into them by the changing rod, which will be hereinafter described. For convenience, I store a number of suitable holders to contain the sensitive plates or films—say eighteen, for example—and when the plates or films are so stored they lay in a horizontal position near the top of the box.

To remove or change a plate or film into position for exposure, I provide a rod, composed of any suitable material and made in such a form that it will withdraw the bottom holder, containing the sensitive plates or films, every time it is operated upon; and by its movement it draws or slides the ends of the plate or film-holder into the stages, as above described, and finally places it in a vertical position ready for to be exposed.

The holders containing the sensitive plates or films are held firmly by three or more springs or catches, and remain in the vertical position until the required number is exposed.

What is claimed is:—1. A photographic camera by which a number of plate holders may be changed in the manner substantially as hereinbefore described. 2. The stages by which the plate-holders are held by the springs or catches, as herein and for the purpose described. 3. The form of changing rod by which the bottom plate-holders in the horizontal position are withdrawn and changed in the vertical position, substantially and for the purpose described. 4. The manufacture and use of the improved camera hereinbefore described and illustrated in the accompanying drawings.

AN IMPROVEMENT IN MAGIC LANTERNS.

No. 18,620. HERBERT CHARLES NEWTON, 3, Fleet-street, London, E.C. *August* 6, 1892.

IN optical or magic lanterns, where large condensers are used to cone the light down through the picture of smaller diameter than the condenser on to the focussing lens, it is obvious that it is advisable to place the picture at such a distance from the condenser that the whole of the cone of light passes through it, so that the utmost illumination may be obtained on the screen.

This object is sometimes attained by moving the slide forward till it reaches the required position, and sometimes by moving both picture and front lens forward together.

These methods, however, while providing adjustment for properly coning down the light through the slide, introduce disadvantages, inasmuch as there is a disturbance of the picture on the screen, owing to the positions of the slide and front lens in relation to the screen being changed during their adjustment with respect to the condenser.

This makes it very difficult to ascertain whether the alteration in position has really increased the illumination, and hence these methods are not generally used.

According to my invention there is no disturbance of the slide and front lens with regard to the screen, but I fix my condenser to a movable base on which the jet also adjusts, so that, leaving the picture and front lens in position, I can rack the condenser and jet (without disturbing their relative adjustment) away from the picture, thus obtaining the same advantage as by the other methods without their disadvantages, as I can rack the condenser and jet backwards and forwards to find the best position without affecting the picture on the screen in any way, except by increasing its brilliancy.

The main features of the lantern are the same as those to be found in lanterns already in the market, but the condensing lens, instead of being mounted as heretofore, is carried in a pair of brackets supported in the movable base. This base also carries the luminant, and is capable of adjustment longitudinally by means of a pair of racks engaging with rack wheels upon the transversely mounted spindle.

Thus the condenser and the luminant, without disturbing their relative positions, can be readily retired from the slide in order to bring down the cone of light to the diameter best suited for the picture to be shown, while the slide and the front lens remain undisturbed with regard to the screen.

The claim is:—Mounting the condenser and illuminating jet of magic lanterns on a movable base capable of adjustment to and from the slide, substantially as explained, for the purpose set forth.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

PHOTOGRAPHY BY RULE.

To the EDITOR.

SIR,—Having read the paper submitted by Mr. Bedding to the North Middlesex Photographic Society, I should wish to enter my protest against the whole tenor of his communication.

Almost at starting he says, "The comparative and particular speed of sensitive preparations have been made the objects of close investigation and valuable experiments; and mechanical aids to exposure have called an apparently inexhaustible supply of inventive genius into existence, the main, and, indeed, the sole object underlying all these efforts being not merely the simplification of exposure and development, but their reference to pure rule and system." Yet his whole argument is an attempt to show that there is no value in these valuable experiments comparable with the method of observing the focussing screen, and thus, by trial and error, ultimately acquiring judgment sufficient to produce technically high-class results. His warrant for this conclusion is his own belief, against which may be cited numerous beliefs to the contrary held by good men and true; consequently some more valid argument than personal belief should be forthcoming to justify the principle (if it be a principle) which he advocates.

Turning again to my quotation, we read, "The simplification of exposure and development." What "inventive genius," I would ask, has endeavoured to simplify, and refer to rule or system, the question of development? Beyond a well-founded assertion that many complications of development, formerly supposed to correct errors of exposure, have not the potency once claimed for them, I know of no such attempt in the question of development. What is this "apparently inexhaustible supply of inventive genius" devoted to exposure? A few cards of exposure notes and two really valuable instruments! If Mr. Bedding decries exposure notes made by other people, he must also condemn exposure notes made by the student! The learner must ignore the observation, made for him by others, that, on discarding one-half of a symmetrical lens, he must quadruple the exposure. He must look at the focussing screen, and guess until he can judge. I hold that it is well to learn by errors, when they occur, but it is better to get rid of as many sources of error as possible before calling the judgment into requisition.

While clearing the ground of all elements of knowledge in order to display the pre-eminence of judgment, Mr. Bedding cuts away the ground from under the feet of judgment itself, for he allows no mode of the formation of judgment but the method of trial and error, *alias* "rule of thumb," which he also disowns. And he refers to the results of "judgment" in the matter of formulæ as "most bewildering." Never have I seen an article so calculated to dishearten and repel a beginner in photography as this one in question; and, unkindest cut of all, if a beginner, resolutely discarding all aids to exposure, produce worse results than his companion with such aid, he must not attribute the other's success to his method, but deplore his own want of brains and give the thing up.

They who wish to monopolise technical excellence may be expected to exaggerate the difficulties in the way of a beginner; but I am sure that this is not Mr. Bedding's object. I therefore am somewhat in doubt whether he intends his doctrine to be so literally interpreted as I have done; but, if he concedes anything, it is hard to see where he can stop. He is urging, he says, the principle of buying photographic wisdom by photographic experience.

If once he admits vicarious experience he abandons the whole position. For what are these aids to exposure but the focus of other people's experience? Scientific reasoning, from the multiplication table and the law of inverse squares, is tested by experiment before it is accepted; and, in using an extraneous aid to exposure, we are taking on trust the judgment of others as far as they can help us in the matter.

If it be true, as Mr. Howard Farmer contends, that distance and colour are not sufficiently taken into account, that does not invalidate the claim that the speed, diaphragm, and light are more correctly dealt with than by mere observation of the focussing screen. Moreover, it is impossible that the learner should, while using the same class of plates, calculate his exposures and observe the illumination without learning the lesson Mr. Bedding wishes to teach; he will soon detect an error in his calculation by the appearance of the ground glass.

Will anybody guarantee to obtain a good negative on an unknown plate? Surely not; and, the more one knows of the speed of his plate in relation to the light falling on it, the less will be left to judgment, guess, work, rule of thumb, and the better will be the results.

The "retrospect" is, I think, altogether unfair; from the days of Jabez Hughes downward definiteness in weights and measures has always been advocated, but from Mr. Bedding's account one would conclude that the balance and the ounce measure were inventions of the present decade. It cannot be shown that pinches and handfuls were more or less common then than now, but we for once find pinches and handfuls of light advocated in preference to calculated quantities.

An annual exhibition of the best productions of photography can give no clue to the rise or fall in average quality of work, and, granting that the average may be lower than formerly, this would only prove that a large number of mediocrities have been called into existence by the modern facilities of photography. It cannot be shown that Mr. Bedding's work is worse than formerly; he can, on the contrary, obtain good results where in old times he could have got none; his facilities for picture-making have increased immensely, and no modern innovation tends to the deterioration of his results.

I have observed operators of long experience and judgment, and find that a new sample of collodion, a new bath, a new brand of dry plates almost invariably leads to error; a trial plate is always demanded; and the man of judgment rectifies his error on the second or third trial, while the novice requires a dozen or more.

Though Mr. Bedding states that he is about to examine some of the principles upon which actinometrical or actinographical systems are based, not a word of any such examination appears in any part of his paper. The paragraph headed "No exposure factors constant" is *not* an examination of these principles, but merely a reminder that the list of conditions may require augmenting. The epithets, "mere empiricism," "falsely inspired formulæ," &c., with which his discourse abounds, would lead one to suppose that he was combating dishonest fictions, palmed off on the public for gain. As I understand the question, this is not the case; the empiricism is on the other side. The factors of exposure calculators are correct as far as they go, and their combined effect is *rationally*, not empirically, deduced; and, Mr. Bedding notwithstanding, the beginner *will* extract from them more reliable knowledge with a dozen plates than the unaided student with a great gross. I strongly suspect that the grey-heads also might learn something to their advantage, how to keep pace with the boys. In conclusion, Sir, I cannot help looking on this paper, from first to last, as a mistake.—I am, yours, &c.,

R. C. PHILLIPS.

The Arts Club, Manchester.

P.S.—I see that some gentleman writes in high glee, assuring all and sundry that he agrees with Mr. Bedding. It turns out, however, that he has never made use of the much-abused "aids to exposure." So I should have conjectured.

The foregoing having been handed to Mr. Bedding, the following is his reply:—

"Mr. Phillips' concluding estimate of my paper as a 'mistake' is perfectly admissible in one who is not indirectly interested in the popularisation of Messrs. Hurter & Driffield's actinograph, which, of course, he includes among the two really valuable instruments to which he makes reference. Upon like grounds, also, I can easily understand why Mr. Phillips regards the paper as calculated to dishearten and repel a beginner. While, therefore, I recognise the ability and am flattered by the length of Mr. Phillips' criticism, I ask his leave to subject his counter-arguments to a reasonable rate of discount calculated in the exact ratio of his partiality.

"With the practised skill of an old debater, Mr. Phillips prefers rather to dissect and examine fragments of the paper than to meet it as a whole, a course which renders it a little difficult for me, except at a length to which I am not agreeable to go, to reply to all the points he has raised. I will, however, briefly deal with the principal ones, and at the outset I shall be glad to waive my own belief in the practical value of the method of trial and error, as applied to exposure, if he is content to place the contrary beliefs of his good men and true in the scale against the work done by the vast majority of professionals and amateurs who do not employ aids to exposure.

"In his third paragraph, Mr. Phillips overlooks my reference to mechanical aids to exposure, *i.e.*, shutters, and seems to be unaware of all that has been written and said on the subject of scientific and rational development, and equally oblivious of the fact that ready-made one-solution developers are articles of commerce. If all these, in conjunction with Mr. Phillips' 'few cards of exposure notes, and two really valuable instruments,' have not for object the simplification of exposure and development, Mr. Phillips will, perhaps, indicate their uses. I agree with Mr. Phillips as to the wisdom of getting rid of as many sources of error as possible before calling the judgment into requisition; but it is at least as important that we should be assured that those sources of error are really removed, instead of merely disguised. Does Mr. Phillips undertake to maintain that in either or both of the two valuable instruments he speaks of no 'sources of error' exist?

"Mr. Phillips' next paragraph is cleverly but unfairly cast. I did not refer to the results of judgment in the matter of formulæ as most bewildering. I never used the word judgment in that connexion at all, but the phrase 'differences of opinion.' Again, I did not convey that 'if a beginner, resolutely discarding all aids to exposure, produce worse results than his companion with such aid, he must not attribute the other's success to his method, but deplore his own want of brains and give the thing up.' May I be pardoned for regarding these and other examples of Mr. Phillips' style of controversy as scarcely worthy of him?

"Mr. Phillips is, I think, unfortunate, and at the same time slightly rash, in looking upon aids to exposure as the focus of other people's experience, and forgets the fact that, in photography as in everything else, a little of one's own experience conveys much more instruction than a great deal of another's. I have failed to discover that even the authors of Mr. Phillips' few cards of exposure notes are really practical photographers, and that any exposure table extant has been compiled from actual experience. I rather fear that a knowledge of mathematics is at the bottom of most of them. I have no objection to take the judgment of others in photography on trust, but I demur to having it thrust upon me as infallible.

"I hope that Mr. Phillips' challenge for a good negative from an unknown plate will be taken up. I have myself successfully used unknown plates (that is, plates with which I had never previously worked, which, I suppose, is what Mr. Phillips means), and if my latter supposition is correct, I should think that even with such a slight guide as a trade description of the plates, any photographer of experience would easily accomplish what Mr. Phillips evidently regards as a great feat. But I do not see the utility of this and several other of my critic's remarks, notably that in which I am accused of advocating 'pinches and handfuls of light,' whatever they may be. The phrase is both a misnomer and an exaggeration. Mr. Phillips' final paragraph is word-splitting and nothing more. If my impeachment of the constancy of the factors taken into account in the systems he speaks of was not the result of an examination of principles, what, pray, was it?"

THE NEW DEVELOPER.

To the EDITOR.

SIR,—Having seen in your last week's issue an inquiry with regard to amidol, I think that, as a resident in Germany, I may be able to give some information with regard to it. A few months ago a new developer, called "metol," was brought out by a firm at Feuerbach, near Stuttgardt, which was much approved of by Dr. Eder and other experts, and which, in my hands, has proved in every way excellent. This is a two-solution developer, requiring the addition of sulphite of soda to the solution of metol as a preservative, and when required for use, the addition in various proportions of a solution of carbonate of potash or of soda, according to the negative required—vigorous or soft. The same chemist has now produced "amidol," which is said to be a similar preparation, but containing in itself the accelerator, and thus forming a one-solution developer. It is, however, not yet on the market, and I have been given to understand that its publication will be withheld until the manufacturer has obtained a marked success, and consequently a large pecuniary return from the sale of the first-named substance. When the "metol" is firmly established, then amidol will be offered for sale, so that it is useless to endeavour to obtain it at present. I would strongly advocate the use of "metol," which is beautifully clear in its action, requiring no alum bath, and developing plates of all brands, films, and Eastman's films with equal excellence.—I am, yours, &c.,

August 26, 1892. ETHEL CONSTANCE MAY.

[Our correspondent is evidently unaware that amidol is already an article of commerce in this country, and, as she will see from other parts of this week's JOURNAL, in actual and successful use.—ED.]

PHOTOGRAPHY IN NORTH QUEENSLAND.

To the EDITOR.

SIR,—I sent you in 1890 a few prints of life and scenery in North Queensland, which you criticised very favourably in your issue of July 25, 1890. I have since been working an 8 × 10 Watson's Acme camera, and am now sending you a few prints taken with same, accompanied by a few notes on amateur photography at this end of the world. It is said there is nothing new under the sun. However, a few of my experiences may prove interesting, if not instructive.

Having been over seven years on North Queensland sugar plantations, I left here on February 5, 1891, to visit the scenes of my childhood in Victoria. On the night of the 4th we registered four inches of rain, so I had seven miles of mud and water to drive through to the landing-place on a mangrove creek. On arrival there I found two feet of water round the wharf, and the little tub of a steamer was high among the mangrove branches Armed with the Acme and a spool of forty-eight exposures in roll-holder, I was soon aboard and bound for Townsville, to catch the intercolonial steamer. When about two hours' sail from our destination, at eight p.m., a squall caught us between the lighthouse and a bad patch of rock. The night was black as pitch, the seas swept the decks, the rain came down as only tropical rain can, and the wind put out the lights in the compass box. To make matters worse, the lighthouse was obscured, and for four hours we were tossed about at the mercy of the waves. I began to fear that neither myself nor the Acme would reach dry land again. However, we did, and in two weeks more I was in my native land.

I was most unfortunate with the Eastman roll-holder and film, but owing to no fault of either. To begin with, part of the holder got loose, no doubt owing to my wet trip affecting the glue. I took it to a photographic dealer's in Melbourne for repairs, and on getting it back did not observe the position of the indicator, which they must have wound on several turns, as the first three exposures I cut in half.

I took train for the river Murray, where I embarked on a river steamer bound for the far-famed irrigation colonies of Chaffey Bros., called Mildura. Light and scenery were all one could wish for to make a set of first-class 8 × 10 pictures. During the five pleasant days I spent on the water, and one day at Mildura, I made some two dozen exposures.

I next made a trip, in a few hours by rail, to the district I had spent my childhood in. When I left there to earn my own living, eleven years ago, it was a long, rough, drive or ride of about ten or twelve hours. Now, the iron horse glides smoothly up the valley of the Goulburn River, but apart from that there seemed to be little change, and little increase of population. Only here and there had the monotonous gum forests given place to cultivated fields. This is due to the extent to which protection is carried in Victoria. The great bulk of the population are in, and close to, Melbourne.

Arrived at the little township near which my home used to be, I found it more slow-going and sleepy than ever. No bell was rung in the hotel I went to (the leading one), and, after hanging round the breakfast-room for a long time, the only other man who was in it remarked to me that, if I wanted breakfast, I would need to go to the kitchen and order it—and so I did. Even *North* Queensland is a peg ahead of that. I exposed a lot more film here, and then went to a sheep station, twenty miles from the township. The night was the coldest I had felt for eight years, and in my bedroom I removed the roll of exposed film in the dark, and then began to struggle with a new roll I had bought in Melbourne. To my dismay, I found it was a roll of cut sheets, and, for the first time, I discovered that I should have asked for a "spool," and not a roll. This ended my photography, though I could have got another forty-eight splendid views. Now comes the worst part of it. On arrival here again, I began to develop, and after cutting three in half, owing to the roll being wound on a few turns by the man who repaired it, I developed the remainder, and found them all hopelessly fogged, owing, no doubt, to the same man letting light into the roll-holder. Such is my experience with Eastman film.

Before leaving Melbourne I purchased two film-carriers to use the cut sheets with. I made one exposure there. Before I got it developed here, I was taken ill and laid up for three months. On recovery, the hot weather had begun, so I did no more photography till May last. I then developed this film, which had been exposed twelve months ago, and got a very good negative.

I store my plates and paper as follows:—I cut the tops out of two 4-gallon kerosene tins, paint them with red lead, then put them back into the case they came out of, which I also paint. I then make a lid with a pad of leather on the under side, which, when shut down and a weight placed on it, makes the two tins quite air-tight. On a very dry day I pack away plates, paper, &c., in the tins, and find that goods so stored are just as good at the end of our rainy season as they were when bought fresh. All the vessels I use to store and carry water in and to wash plates are made by myself of tins painted with three coats of red lead. I have two kerosene tins on a high shelf and a small piece of rubber tube leading from them to the table I work at. I have a big wash-up dish, also painted, over which the tube hangs, and is very handy for washing plates when changing from one solution to another. My shelves are kerosene cases one above the other, laid long ways for small bottles, and end up for long bottles.

Negatives, 8½ × 6½, I keep in "Pain Killer" boxes, and I fold a sheet of foolscap once, and place the negative between, with the number and subject written outside; 8 × 10, I have to make boxes for, and use a double sheet of foolscap cut to size.

I stick to the old-fashioned pyro-ammonia developer. I do not put my prints into an album or mount them on cards, but bind them in a novel way of my own, a description of which may be of interest. Whole-plate views, for example, I print on paper cut to give a margin on the top, which is masked while printing. Into a wooden frame, which I made for the purpose, I place, first, a sheet of strong but thin paper, exactly the same as I am writing on, but not ruled, of course; then a print with masked margin exactly over the edge of the first sheet of paper; and so on, a print and a sheet of paper alternately, till a book of twenty-four or forty-eight is complete. I then punch holes along the upper edge through both print and paper, and bind all together with fine copper wire. For the cover, I salt, and sensitise, and expose to light, and tone to a warm brown, two sheets of some strong paper, and finish off bound edge with a

strip of the same. Now just a touch of starch paste to each loose corner of print, and the book is finished.

Such a way of keeping prints has many advantages. Several hundred occupy a very small space; they will stand any amount of handling without being damaged or the cover showing finger-marks; the prints being bound into the book, no mountant is used, except at the two lower corners, hence they are not so likely to fade. I carried all my collection of prints everywhere when I was away in the south, and they were handled by scores of people; but they are in as good order to-day as when first printed. A description of each can be written on the page opposite the view.

In an out-of-the-way place like this one has none of the luxuries and advantages of a town, such as gas and water laid on and the like, but has to make all kinds of contrivances for himself.

I also go in for lantern slides, and reduce most of my views to lantern slides in the camera in a dark room, with hole in window for negative, and sheet of white paper outside. We have a Watson's lantern and a 12 × 10 sheet sized and whitewashed, which we erect in the stable yard on dark Saturday nights, and display to the astonished South Sea Islanders pictures of themselves larger than life size. They come from another plantation, sixteen miles away, to see it, and are never tired. They would stay all night if we kept it up.—I am, yours, &c.

D. Macfarlane.

Pioneer Estate, Lower Burdekin, viâ Townsville, N. Queensland.

[Our correspondent's letter was accompanied by several photographs of the natives of the New Hebrides, views in North Queensland, &c., which, considering the difficulties under which he has to work, are excellent in all respects.—Ed.]

MR. C. W. HASTINGS.—DISSOLUTION OF PARTNERSHIP.

To the Editor.

Sir,—Will you allow me to inform your readers that the partnership which existed between myself and Messrs. Hazell, Watson, & Viney, Limited, in connexion with their photographic publications, has been determined, and that I have no direct or indirect interest in the photographic publications issued from the offices of the *Amateur Photographer*, Messrs. Hazell, Watson, & Viney, Limited, having acquired all my interest by purchase this day.—I am, yours, &c.,

Charles W. Hastings.

Manor-road, Sidcup, Kent, August 27, 1892.

DECOLOURISING SHELLAC VARNISH.

To the Editor.

Sir,—You are perfectly correct in saying it is useless to attempt to decolourise shellac varnish by shaking it up with animal charcoal and setting in the sun. There are two or three points to be attended to in order to secure success. Firstly, the animal charcoal *must* be quite fresh, and recently carbonised; and, secondly, the varnish *must* be *boiled* with the charcoal, and not merely shaken up with it. Now, although this will not absolutely decolourise the solution, it will effect a *great* improvement; *the strong yellow colour will be removed*, and the resulting varnish will be a good, workable varnish, in which the colour that remains will be of little consequence in the thin film on a varnished plate.

I have found the following plan answer very well:—Procure a glass flask of, say, four ounces' capacity, put in half a pound of freshly burnt animal charcoal, then fill it about three parts full of the varnish to be decolourised; boil hard for a quarter of an hour or twenty minutes, cool and filter; sometimes half an hour's boiling will be required. The narrowness of the neck of the flask will prevent much waste. If this will not remove sufficient colour, boil it with a *fresh* lot of charcoal. The resulting varnish appears somewhat dark *in bulk*, but is not so in reality, as the bright orange colour will be destroyed.—I am, yours, &c.,

August 29, 1892. Edwd. Dexmore.

To the Editor.

Sir,—I have noticed from time to time what difficulties there seem to be in obtaining a clear solution of shellac without great waste. I have always succeeded by filtering through silver sand.

Have an ordinary tin funnel made in two parts, the upper part should have a piece of linen tied round at the bottom to keep in the silver sand, which should be clean and filled about half way; allow a little methylated spirit to run through before putting in the varnish, the deposit will accumulate on the top of the sand, and as it does so it can easily be removed by a spoon, and which will cause the varnish to run through quicker, the result will be a clear solution without waste.—I am, yours, &c., Arthur Bloo.

The Studio, Finborough road, Stowmarket, August 29, 1892.

THE DECAY OF PROFESSIONAL PHOTOGRAPHY.

To the Editor.

Sir,—It is the decay of the apprenticeship system that will ruin professional photography, as it is ruining many other businesses which require long and patient practice to produce experts.

These technical schools, where lads for a few shillings a quarter learn to cackle a garbled miscellaneous collection of chemical formulæ, flood the profession with a host of young fellows in their own estimation first class in everything, but, as I have found to my cost, really clever in no single branch of the business. Unfortunately some of the teachers in these technical schools are blind guides, who, having failed in business as photographers or chemists, eke out a precarious income by professing to teach what they know very little about.

You deplore the fact that a professional photographer does not personally execute his own operating, retouching, printing, enlarging, &c. A photographer's place is in his studio, and therefore, if he has anything like a business, it is impossible for him to do more than engage clever assistants to manage these departments, and see that the work is well and thoroughly done.

Notwithstanding your dictum, I maintain that *most* respectable photographers execute their own retouching, finishing, mounting, &c., on the premises, and do *not* give it out. A very large number also do their own enlargements. I have had a large experience of the pupils of these technical and polytechnic schools during my twenty-five years of professional photography, and I remember I foolishly engaged one assistant on the strength of the credentials he had from one of these institutions. He asserted that he was (amongst other things) a *first-class* operator, but I found he had about as much idea of making a graceful portrait as an Imbecile Hottentot. I was very gentle when I gave him his month's notice, because I thought, "It is not the fault of this poor youth, but it is through the folly of his parents, who did not apprentice him to a good photographer, when he would (if he had possessed ordinary intelligence) have been taught to be of some use."

Portraiture and photography are two totally different professions, only long and patient study in a professional studio can make a good portraitist. The tongue of the operator is as potent as the chemicals in making a successful portrait, and no technical teacher can impart to a pupil the tact a portraitist must acquire. Then, again, can the technical teacher take his pupil to picture galleries and exhibitions, and teach him what to copy and what to avoid? Can he set his pupil by the side of an expert retoucher and show him the negative the lad has assisted to take skilfully retouched? Can he send him into the printing-room and let a competent printer show him how to make the best possible prints from the negative? No, sir. It requires from three to five years to teach him all this, and he must be a clever lad to start with, into the bargain.

It is a significant fact that if I want a really useful assistant I have to train one myself, or else employ a young gentleman from the continent who has been apprenticed for a term of years with some good firm, and consequently is an expert at what he professes to do for his money.

And now, sir, let me point out the harm your article will do the profession. The amateurs whose name is legion all read the photographic literature; they will very naturally quote this article as an authority when consulted by non-photographic friends as to the best means of having their offsprings taught photography. The result will be that the tender suckling will miss the instruction he will need most, will ultimately start in business with a smattering of chemical knowledge only, will fail as a matter of course, will struggle on by working at starvation prices, and the premium which the photographer would have given good value for goes into other channels.—I am, yours, &c.

Augustus W. Wilson.

13*f*, *Dalston-lane, Kingsland, August* 30, 1892.

Exchange Column.

*** *No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.*

Samuel's Patent hand camera, two finders, holds twelve plates, perfect condition; exchange for 10 × 8 or 12 × 10 rectilinear lens.—Address, T., 7, Abercorn-terrace, Upper Holloway, N.

Will exchange Lancaster's 1891 Special Instantograph, two slides, lens, shutter, quarter-plate carrier, ash stand with adjusting top, complete in good condition, for safety bicycle.—Address, Howard Artiss, 91, Potters-hill, Aston, Birmingham.

Photographic Club.—September 7, *Enlarging*. 14, *Transparency Printing*. Outing, September 3, Finchley and Dollis Brook. 10, Greenwich.

Messrs. George Houghton & Sons have recently despatched to America a Moessard's pattern panoramic camera to take pictures 48 × 15, which is said to be the largest of its kind made, having taken several months to construct. The details of the instrument have been well thought out.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," 2, *York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

William Vass Morris, Cork.—*Photograph of lugger yacht "Windfall."*

Edmund Smith Baker, jun., Birmingham.—*Photograph of Fire Escape.*

Richard Cobden Philips, Manchester.—*Photograph of Mrs. Alexander Ireland and Annie Elizabeth Ireland.*

FRANK WELLS.—The Autotype Company, of 74, New Oxford-street, W., undertake chromotypes.

JAS. B. ROSS.—You are precluded by the patent from either making the paper for use or from selling it.

T. WALLIS.—All materials for working photo-lithography, or zinc etching, may now be obtained from most large houses that supply printing material.

MECHANIC.—Apply to the Aluminium Company, Cannon-street. If they do not supply the castings, they will, doubtless, tell you where they may be obtained.

A. Z.—Your description of the defects is far too vague for us to form anything like a definite conclusion as to the source of the trouble. Send one or two examples.

EXHIBIT.—The Exhibition of the Photographic Society of Great Britain opens at the Gallery of the Institute of Painters in Water Colours on Monday, September 26 next.

D. C. MORGAN.—*Pure* zinc is several shillings a pound, but the ordinary metal, such as is used commercially for building and similar purposes, will answer quite well for reducing silver from residues.

C. BROWN.—If you do not succeed in getting satisfactory casts with paraffin wax, try plaster of Paris, using the finest kind. This may be obtained from those who make modelling in plaster a specialité, such as Brucianni's.

REX.—The drawing of the finder you submit is quite correct. When standing behind it, the sky of the landscape will be farthest away from you. A double convex lens of two and a half to three inches focus will answer quite well.

C. SOLOMONS.—If the business was sold under a misrepresentation, of course the purchaser is perfectly right if he repudiates the transaction or institutes proceedings for the return of the purchase-money. If he proves his case, he will certainly succeed.

F. SIMS.—There is no possible objection to using the 5×4 "rapid" lens for half-plate pictures, provided it will do the work. It will, however, embrace a wider angle than a lens specially constructed for half-plates, and thereby give a more violent perspective.

H. S.—It seems that the agreements are informally drawn, or rather not as a solicitor would word them, but that is not of much moment. It is usual to have one or more witnesses to attest the signatures. However, as the documents are not stamped, they are of no value.

J. C. DAVIS.—Within reasonable limits, the proportion of gold to sulphocyanide is not very material. You might safely replenish the exhausted bath with fresh gold for three or four times without the addition of sulphocyanide, when a fresh proportion of the latter would be advisable.

W. W.—Unless the colour of the paper upon which the engraving is printed is of a more or less yellow shade, there will be no advantage gained by orthochromatising the plates. The best plates for the purpose are those supplied for photo-mechanical purposes, or such as give great transparency in the blacks.

BEGINNER (Croydon).—A studio ten feet long and six feet wide will be of very little use, even for a beginner. If your means at present will not admit of building a larger one, it may be well to defer its erection for the present, and in the meantime, with the aid of a few curtains, utilise a shaded portion of the yard.

C. HURTMAN.—Stereoscopic transparencies backed with ground glass, are not suitable for use in the lantern, unless that be removed. Even then they are rarely so good as transparencies specially made for lantern purposes, as they are usually too dark. A transparency that is of the right density for the lantern will be too thin as a stereoscopic slide.

PROCESS.—If your only difficulty lies in obtaining electrotypes from the moulds, we should advise you, in the preliminary experiments, to take them to a practical electrotyper who is experienced in that particular class of work. When you have proved that the method is thoroughly practicable, and that it will yield good results, then give attention to the electrotyping part of the process.

R. MCCONCHIE.—1. All the troubles seem to point to impurities in the materials used, or uncleau vessels. If the former, the water particularly might be suspected first. Try making the toning bath with the ordinary tap water, that has been boiled for an hour or two and allowed to cool. The small amount of light the toning bath is exposed to would not account for the trouble. 2. Better use an emulsion paper if a surface with a fine gloss is desired. This is not to be obtained on drawing-paper when squeegeed on glass. One of the photographic papers, Saxe or Rives, should be employed if a surface giving the finest detail is desired. When an emulsion is prepared, it should be used withiu a short time of preparation, and not kept in stock.

F. E. G.—1. To copy an object so that the photograph shall be the same size as the original, it is absolutely necessary that the camera shall be extended to twice the solar focus of the lens. It may be necessary for you to add a small piece to the camera front so as to get the lens farther from the ground glass. 2. Probably air bubbles or impurities in the hypo. Try a different sample of the latter, or use a pledget of cotton-wool with that which you are using.

REFLECTOR.—1. The image thrown on the horizontally placed ground glass will be of the same dimensions and sharpness as if it were received at the end of the camera. 2. In taking portraits by the aid of a mirror, as described, while it would be theoretically better that the silver should be deposited on the front of the glass, in practice it is advisable that it should be protected by the glass, as the double reflection causes no inconvenience, owing to the feebleness of that from the front surface. 3. By bringing the lenses of a rapid rectilinear nearer together, whether it is done by rackwork or otherwise, a larger field of illumination will be obtained, at the expense, however, of roundness of field. We would strongly advise you not to effect such an alteration of the mount, especially if the lens be a good one.

A COUNTRY PHOTOGRAPHER writes: "I have a series of copyright photographs, and last year gave permission to the editor of a leading monthly publication to reproduce certain of them to illustrate an article in that publication, under the conditions that my name appeared under each as the photographer. This was done. I find that this year, in another publication by the same publisher and on a similar subject, these photographs have again been used, entirely without my knowledge and sanction, and without my name appearing in any way. Will you advise me as to the best course I can take in the matter?"—It appears to us that you, although having given permission to use the photographs for a certain purpose, under certain conditions, does not entitle the same or any other person to use them for any other purpose whatever, except with your permission. Your remedy is to proceed against the parties for infringement of copyright. But, before doing so, we advise you to consult your solicitor. You can, however, do no harm in writing a formal letter to the offending parties for an explanation.

T. W. EDWARDS says: "During the past week I have experienced great trouble with my silver bath, and appeal to you to help me out of the difficulty. My silver bath has worked well for a considerable time now, and my batches of prints would tone within twenty minutes, but now I cannot get them to tone beyond a reddy-brown, bleached-out colour, although I have tried a new toning bath. Silver bath does not seem to be acid. I have put carbonate of soda in it, and have filtered also. The solution, after standing, is quite clear, and I am at a loss to know what can be the matter with it. My toning bath is the ordinary acetate bath, which I have worked for years with success. Silver bath I keep up to sixty grains, with kuloin in it, and add a little carbonate of soda twice a week."—Supposing no change has been made in the kind of paper used, there is little doubt that the silver bath is too weak. The argentometer is not always a reliable test with baths that have long been in use. Make up a small quantity of new bath, sixty grains to the ounce, and sensitise a little paper on that, and see the result.

S. W. B. writes as follows: "Would you give me an answer to the following difficulty? I have three bromide prints, which I value highly, and, as the negatives have been hopelessly spoilt, I cannot produce copies of them. They are all of small size (quarter-plate), and, though I nave tried copying them in the camerr, I can get no satisfactory result. Is there any process by which I can free the film from the paper, and then transfer it to glass? I have not dared to try hydrofluoric acid, as I was afraid it might not act on paper positives."—There ought to be no difficulty in copying the pictures in the camera. It would be very risky to attempt to strip the gelatine film from the paper, and, if it could be successfully accomplished, the operation would be troublesome and to little purpose. Hydrofluoric acid would not assist. If the prints are unmounted, they might be used, perhaps, for printing on to a dry plate, with a view to making a fresh negative that way. But the best result will be obtained—and this ought to be nearly equal to the original—by copying the prints in the camera. Try slow plates, and do not over-expose.

LEYTONSTONE CAMERA CLUB.—There will be informal meetings on September 3, 10, 17, and 24.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—Next Meeting, Tuesday, September 6. Subject, *Comparison of Holiday Work.*

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.—Mr. Chapman Jones, the Hon. Sec., writes:—"Will you kindly remind your readers that Wednesday, September 14, is the only day for receiving exhibits at the gallery for the exhibition of the Photographic Society of Great Britain, and that exhibits may be sent at any time up to September 13 to our agents? Full details can be obtaiued by application to the Assistant Secretary, 50, Great Russell-street, Bloomsbury, W.C."

AMIDOL.

New developers not infrequently suffer in public estimation from a failure on the part of their introducers to indicate with sufficient exactitude not only the precise nature and the proportions of the developing solutions of which the new substance is to be a constituent, but also in respect of the great and far-reaching claims which are urged on their behalf, without anything more than the results of a few private experiments to justify or attest them. Naturally inventors are prone to look upon the efforts of their skill with a favourable eye, a view which experience has over and over again shown that an impartial public has failed to ratify; and thus perhaps we can understand how it is that, in the case of new developers, the rivals which were confidently expected to drive pyrogallol from the field have so far failed to effect that purpose. This, however, is no denial of the valuable properties which, under certain conditions, hydroquinone, eikonogen, and para-amidophenol undoubtedly possess.

Amidol, so far as we are aware, has not been heralded by any considerable flourish of trumpets implying that it is to revolutionise development; and thus, whatever the final place it has to occupy in the photographic formulary, it will be safe to conjecture that it will neither create nor perpetuate a sense of disappointment. Early as it is, however, we are inclined, both from our own and the experiences of others, to forecast something more than a transitory popularity for amidol. As our readers have already been apprised, it is a developer *per se* —that is, the use of an alkali with it is unnecessary, although it is only in the presence of sodium sulphite, which practically performs the office of an accelerator, that its full developing properties find sufficient scope to be practically utilised. In our brief allusion to it of August 12 we indicated the chemical composition of the new reagent, although possibly that is merely its theoretical formula, so that, under analysis, it might give a somewhat different reading of the equation. This, however, is merely conjecture.

Those responsible for the introduction of amidol as a commercial article in this country are to be congratulated upon having provided a formula for its employment which, both in our own and others' hands, requires little or no modification in order that the principal properties of the new developer may be deduced from experimental use. It is, in fact, on that account easier to institute comparisons of the new substance with, for example, pyrogallol, than it was to accurately compare hydroquinone or eikonogen with that developer. We have not found it necessary to vary the proportions of the stock solution of 20 parts amidol, 200 parts sodium sulphite, in 1000 parts of water, with which our first trial of the developer was made, and can therefore recommend those of our readers to adhere to these proportions.

The first question which arises in considering the properties of a new developer is, what are its advantages or disadvantages as compared with pyrogallol — still, in all probability, the standard developer for negative work, and probably the most effective? We may at once state that amidol, practically considered, has no discoverable disadvantage compared with pyrogallol, while as to its positive properties we are disposed to consider it as perhaps the most dangerous rival which pyrogallol has thus far had to encounter. Used in a strength of three parts of water to one of the stock solution above described, its rapidity of action upon a correctly exposed plate is remarkable, weakening by dilution appearing neither to retard its rapidity nor decrease its energy of attack in anything like the same degree as with other developers. Used without bromide, however, it appears to us to have a tendency to set up a surface veil, even with correctly timed negatives and development retarded by dilution, and thus we find the invariable employment of a small quantity of bromide—about one-eighth of a grain to the ounce—as decidedly advisable of course increasing the quantity as development progresses in accordance with requirements.

With that small addition of bromide, the image has all the best characteristics of one developed with pyrogallol in collaboration with an alkaline carbonate, the finer details being perfectly rendered, while the control of density is so thorough that, given proper exposure, with a developing solution such as we have specified, practically any degree of intensity is obtainable with little prolongation of development beyond the normal period. Dried negatives very closely resemble pyro-developed *clichés* in colour, but are much clearer and freer from stains, inasmuch as the solution undergoes little, if any, discolouration during use. Indeed, we have left some in an open graduate for several hours without observing any change in its appearance, although at the end of a day a rapid degradation of colour supervened, with, at the same time, an almost total loss of developing power. On the other hand, amidol's conservation of developing energy in a solution in actual use is exceptional, for, in submitting ten plates to the action of one developing solution, we found that the difference in time occupied by the first and tenth plates was so small as to be neglected. In brief, amidol appears to render vigorous, yet harmonious and soft, negatives of a pyro-like character, with the advantages that it is quicker, cleaner, more energetic, and more economical than the older reagent.

Without going so far as to class amidol as a universal developer, we are persuaded that it has great possibilities for paper positives, inasmuch as on bromide paper it yielded us results quite the equal of those given by eikonogen, that is, the colour of the image was of a warm black, with the shadows free from clogginess, and it did not discolour the whites. For lantern slides it scarcely appears so well suited, since, while the colour of the deposit is not so rich as is generally desired, it seems a little difficult to escape a certain veil which detracts somewhat from the brilliancy of this class of picture. We do not doubt, however, that further experience will obviate these slight defects.

On the whole, we lean to the opinion that amidol is a valuable addition to modern developers, with certain advantages of its own, which place it at least on an equality with each or any of its rivals at their best. A point greatly in its favour is its easy solubility in water, and it should, in conclusion, be pointed out, that not only is the addition of alkalies needless, but that the latter practically destroy the developing properties of the amidol-sulphite solution, while as restrainers the organic acids sometimes used for that purpose have no advantage over plain potassium bromide.

FINISHING GELATINE PRINTS.

Few of those who regularly employ gelatino-bromide or chloride papers have become so completely diverted from the old style of albumen print, with its glassy surface, as to be satisfied with the comparatively rough surface of the modern gelatine print, for small work at least, when it is not glazed or finished by transfer from a glass or other polished surface. At the same time, many complain of a difficulty in securing the necessary finish, and speak in unkind terms, consequently, of an otherwise satisfactory style of print.

And yet the process of enamelling or glazing the prints is one of the simplest and easiest it is possible to have to perform if only a few plain rules and precautions are observed, for which reason we are inclined to think that at least the greater part of the trouble complained of is due to some carelessness on the part of those concerned, or possibly to a want of knowledge of the details of the process. In the latter belief, therefore, we propose to give simple details of the manipulations in the most practical methods of procedure.

The old style of enamelling silver prints consisted in cementing the prints in contact with a collodionised sheet of plate glass, from which, when dry, it was stripped, bringing with it the film of collodion, and presenting a surface equal in brilliancy to that of the glass itself. In the more modern methods the preliminary film of collodion has been dispensed with, and, the polished surface of glass or other material having been suitably prepared, the print is squeegeed directly into contact with it and left to dry, when it can be stripped with the greatest ease and carries a surface little, if at all, inferior to that obtained when collodion is employed.

It need scarcely be said that the older and more elaborate method is the superior so far as stability of result is concerned, or that the collodion film adds materially to the permanence of the photograph itself by forming a transparent protective layer on its exposed surface. Where the extra trouble is of no consequence, therefore, that method will, no doubt, be adopted, but for ordinary purposes the simpler plan will usually answer every requirement.

Briefly, the method as employed with albumen prints consisted in bringing the two surfaces of albumen and collodion into intimate contact, each having first received a coating of colourless and clarified gelatine to cause perfect adherence. With gelatine prints the procedure is identical, except that in many instances the adhesive may be omitted. This is more especially the case with "printing-out" papers whose gelatine surfaces, being mostly unhardened by either alum or the action of development, prove sufficiently adhesive in themselves without any extraneous acid. With developed prints, and in some cases with the undeveloped, where alum has been used in the manufacture of the films, it will be found safer to employ the adhesive, in order to be certain that the surfaces shall adhere in every part, a thin solution of gelatine answering the purpose.

The first step in the process consists in thoroughly cleaning the glass, which should be perfectly free from scratches or flaws, each of which would be faithfully reproduced on the surfaces of the print. The cleaning is done with alkali, followed by copious washing in clean water, after which the glass is dried and polished with a soft linen rag. In place of glass it is now the practice frequently to substitute sheets of polished ebonite or ferrotype plates, which have the advantage, partly owing to their flexibility, that they allow the prints to strip more easily. These must be as scrupulously cleaned as the glass.

The final treatment of the temporary support, previous to collodionising, is to polish with a solution of wax in benzole, chloroform, or ether, or, as many, including ourselves, prefer, with powdered talc or French chalk. The wax solution is made by dissolving a small quantity of pure beeswax in one or other of the solvents named, which must be perfectly free from grease. A little of this solution is poured on to the glass or other support, and rubbed well into the surface, and then polished off with an old silk handkerchief. If French chalk be used, it must be dusted pretty freely over the surface, and then polished off until no traces of it are visible.

The collodion to be next applied is made by dissolving from six to eight grains of good soluble gun-cotton in an ounce of a mixture of equal parts of alcohol and ether. A suitable sample of gun-cotton can be obtained for not more than a shilling the ounce; methylated ether of s. g. ·720 is the correct thing to use, and we have found no detriment to arise from the employment of the new "mineralised" methylated spirit, provided its strength is not lower than ·825. The collodion is poured on to the glass or other support in the ordinary manner, allowed to set, and then immersed in water until the latter flows freely and evenly over the surface without apparent greasiness; it is then ready to receive the print.

In the case of the softer kinds of printing-out paper, no preparation of the surface of the print is necessary, all that is required being to bring print and collodionised glass into contact while both are under water, so that no air bubbles are enclosed between the two surfaces. On drawing them out of the water bath, simple pressure beneath several folds of blotting-paper will ensure perfect adhesion, or, if preferred, the squeegee may be used. If the gelatine surface of the print has been hardened by alum, or by development, it will be advisable to apply an adhesive, which may consist of a ten-grain solution of gelatine, of course used warm. The print having been floated on this solution, and a plentiful supply of the latter having been poured on to the collodionised glass, the two surfaces must be brought together in such a manner as to avoid air bubbles, and the surplus gelatine squeezed out by means of the squeegee, and the whole then left to dry.

When the simpler plan is used, and the collodion film dispensed with, success depends principally upon the proper preparation of the surface of the print. The support, and in this case ebonite or ferrotype plate is preferable to glass, is prepared in the same manner as before, up to and including the polishing with wax or talc. The print is prepared by a thorough "aluming," that is to say, it must be immersed for some minutes in a saturated solution of alum, followed by a good washing, after which it is brought into contact with the prepared support, under water as before, and otherwise treated as already directed. Should the gelatine surface exhibit any tendency to adhesiveness, the two surfaces may be brought together in a mixture of equal parts of alcohol and water, which, by further hardening the gelatine, will destroy its tendency to stick.

The prints, when quite dry, will strip easily from the support if a narrow strip be cut off each edge with a sharp knife, which is then inserted under one corner of the picture, and then stripped off by means of a firm and steady pull.

As the glaze is lost if the print be damped after stripping, it is necessary to mount it while still in contact with the support, or to make arrangements for its mounting without loss of gloss. In the first case the flexible support proves extremely convenient. The print is trimmed to size *in situ* and carefully covered with mountant, the mount itself being then placed in position, and the whole put under gentle pressure until dry, when mount and temporary support are easily separated. If the mounting is to be performed after stripping, it will be necessary to apply to the back of the print by means of gelatine, while still on the support, one or two thicknesses of even white paper. This will convert the print when stripped into a sort of thin cardboard, which will admit of the edges being tipped with gelatine, and the print mounted without cockling or loss of gloss.

A very neat method of mounting we saw in practice some time ago is worth describing. A number of ferrotype plates, having been cut to the exact size of the print when mounted, were cleaned and prepared by polishing with ordinary vaseline. The prints, having been squeegeed in contact, were trimmed down to the size of the supports by means of scissors, and while still damp the mountant was applied, and the prints with their supports placed in position on the mounts, and pressure applied until dry. The flexible ferrotype plate was then easily removed, leaving the print with a beautifully enamelled surface. The use of vaseline appeared to us to be a valuable improvement upon either wax solution or powdered talc.

PHOTO-ZINCOGRAPHY.

From remarks we from time to time hear, and from queries received of late, with reference to photo-zincography, it is clear that not a few are under quite a misconception as to what is photo-zincography. The queries, as put, more often than not refer to another process in which zinc forms the printing matrix. What is so often confused with photo-zincography is the zinc etching, or, as it is more frequently termed in the trade, the "zinco" process. The two processes are totally different both in principle and in practice. The one is for the production of blocks in relief for printing in the typographic press, whereas the other is a surface-printing method by which the impressions are obtained after the manner of lithography. With a view to clearing away this confusion, we shall give a brief description of the photo-zincographic process proper, when it will be seen how widely separated it is from the process with which it is so often confounded, even by some who work it or are experimenting with it, while, at the same time, it will also be seen how very closely photo-zincography is allied to photo-lithography.

It may be explained at once that the practice of photo-zincography, like that of photo-lithography, is principally confined to line subjects. The former process, it may also be mentioned, is not worked commercially, or ever has been, to the same extent as the latter. Why this is the case it is somewhat difficult to surmise, unless it be that this class of work has principally gone into the hands of lithographers who were more familiar with the manipulation of stone than zinc. It is quite conceivable, however, that had the commercial working of the process in the first instance been taken up, as it really ought to have been, by photographers, as the essential parts of it are purely photographic, the metal would have been preferred to stone. The process is, however, extensively employed for the production of maps, and for other purposes where fineness and delicacy of detail are necessary. All our ordnance maps, for instance, in which, of course, extreme fineness is an essential, are produced by this process, and so are those of some foreign and colonial governments.

Zincography, like lithography, as most are aware, is based upon the antagonism of grease and water, and that the first thing to do is to obtain the photographic image, whatever it may be, in a greasy material. For this purpose advantage is taken of chromated colloid substances, which it is tolerably well known to all our readers become insoluble, or non-absorbent of water, on exposure to light. In the early days of this class of work the sensitive body was applied to the metal or stone, and that exposed direct behind the negative. This system obviously was attended with great disadvantages. Pressure frames containing large metal plates or stones were, it is needless to say, very inconvenient to handle, and, moreover, a difficulty was found in getting perfect contact with all portions of the image. After a time this system was abandoned for the transfer method—the one now universally employed.

There are several different ways of producing the transfers, each of which has its advocates, though all are based upon the same principle. One method is to coat a fine surface paper with albumen, gum arabic, or other similar substance, or a mixture of two or more of them, containing bichromate of potash or ammonia. When this coating is dry, the paper is exposed behind the negative until a strong image is obtained on the pale yellow ground. The paper is then coated uniformly with a fatty ink. Specially prepared photo transfer ink is now supplied by all large dealers in printing materials, and this thinned with turpentine answers very well, though some workers still prefer to make their own transfer ink. After inking, the paper is floated on cold water, which dissolves the coating where the light has not acted, bringing the ink away with it and leaving the design perfect in ink on the hardened colloid material.

In place of employing gum or substances soluble in cold water, gelatine is more generally used. It always is at the Ordnance Survey Office, Southampton. When the image is printed and the paper inked up, it is floated on tepid water until the unacted-upon-by-light portions swell up, then the coating is treated with hot water to dissolve them with the ink away. Hence the same end is arrived at as when albumen

or its analogues are used—namely, the lines in greasy ink on a hardened colloid body with bare paper for a ground.

Instead of treating the inked-up print, after soaking in cold water, with hot water, the ink is by some workers removed from the unexposed portions by gently rubbing with a soft sponge or brush and copiously washing with water. When the unacted-upon gelatine becomes saturated with water, it has no longer any affinity for the greasy matter, while those portions that have been exposed to light still hold it tenaciously. Here is another method. In place of inking up the print direct as it is taken from the negative, it is soaked in cold water and then blotted as dry as possible. Then the ink is applied, when it adheres only where the light acted. It will be seen that in the two latter methods the colloid film remains intact on the paper, while in the former ones it exists only where it has been modified by light.

With regard to the application of the ink to the exposed film, there are several ways of doing this. Some prefer to use a dabber, some a soft roller, such as the velvet roller, while others apply an even layer of the ink, in the first instance, to a zinc plate or a lithographic stone, and then pass the undeveloped print several times through the litho press in contact with it. By whatever means the fatty image is obtained, the after-operations of transferring and printing are the same.

After the transfer has been dried it is placed between sheets of damp blotting-paper until it has become quite moist. A zinc plate, that has been planished and finely ground, and made perfectly clean, is placed on the bed of a lithographic press. The moistened transfer is then laid upon it with a few sheets of paper as a backing. The whole is then passed several times through the press, the pressure being increased each time. Next the back of the transfer is wetted with water and the paper taken off, leaving the ink forming the image firmly adherent to the plate. After washing with water, to remove any adherent fibres of paper, the surface of the zinc is treated with dilute phosphoric acid, gum arabic, and nut galls in water. After remaining on for a few seconds this is washed off, and the plate is ready for inking up and printing from, either in a hand or a power press, just as if it were a lithographic stone.

From the above brief description it will be seen how widely different is photo-zincography proper from what is commonly known as the "zinco process," and also how closely it is allied throughout all its manipulations to photo-lithography, so much so, that it becomes practically identical with it, except that metal is employed in place of stone.

Mention was made in an early part of this article that zincography is less extensively employed in commercial work than lithography. This may possibly, to an extent, be accounted for by the fact that less skill is required in printing from stone than from zinc; though it is claimed for the metal that in skilled hands it yields finer and more delicate results than can be obtained from the stone.

Camera Club.—The winter indoor meetings of the Camera Club will recommence early in October, when a new Exhibition of photographs will be opened. It is intended to gather two or three examples from each of a number of prominent photographers, to be selected as far as possible by the exhibitors themselves from recent work. The premises of the Club are at present in course of redecoration.

The Admiralty and Scientific Expeditions.—We are sorry to hear a rumour that the Admiralty have refused to render any assistance in carrying the observers and instruments for which the Royal Society made application some time ago to further the observations of the total solar eclipse in Senegambia next April. We presume, if the rumour be correct, there will be no expedition.

A Strong Solution of Ammonia.—The common aqueous solutions of ammonia are sufficient for all ordinary purposes, but cases arise where an alcoholic solution is needed. The drawback to this latter is the fact that it contains so much less ammonia than the aqueous solutions. Thus, at 58° F., an alcoholic solution of eighty per cent. (and that is weaker than ordinary rectified spirit) will only hold nineteen per cent., while the familiar solution contains, when of full strength, over thirty-two per cent. Methyl alcohol, however, dissolves an enormous quantity. According to M. J. Delépine, he states in a technical journal that a purified commercial alcohol containing less than three per cent. of acetone dissolves forty per cent. of its weight.

Photographs of Bees.—Mr. T. E. Freshwater recently showed us several of his excellent photographs of bees, which, while undoubtedly of peculiar interest to bee-keepers, are of scarcely less account from a purely photographic standpoint. The photographs, of which there are several, illustrate various phases of bee culture as conducted by Mr. Broughton Carr, a well-known apiarian, such as hiving, catching the queen, and many other operations involving the manipulation of a swarm of bees, numbering probably many thousands. A set of lantern slides has also been prepared, which, judging by the well-defined appearance of the masses of bees under the magnifier, should be highly successful on the screen. We understand that the photographs have aroused much interest among the members of the British Bee-keepers' Association. One of them shows a number of bees crawling over Mr. Carr's hand.

Cyanide of Potassium.—Dr. Kayser, of Nuernberg, recently read a paper on this substance before a meeting of the Free Association of "Bavarian Representatives of Applied Chemistry," which, though not specially photographic in substance, is yet interesting as increasing our knowledge of a well-known chemical. He states that the so-called potassium cyanide of commerce usually contains a very large proportion of sodium cyanide. He points out that this impurity is of technical importance in preparing galvanic gold baths, the potassium auro-cyanide being very soluble, while the sodium salt is sparingly so. The query presents itself, what would be the effect of a greatly over-printed silver print strongly toned with gold, and then submitted to the action of cyanide of sodium alone? In the new edition of Watt's Chemistry, the auro-potassium cyanide is described, but the sodium salt is merely referred to.

Wire Glass.—Under this name a new material has been put upon the market, and there seems no reason why it should not be used for many photographic purposes if it can be turned out of the required substance and clearness. The process of manufacture consists in furnishing glass in a hot, plastic state with a flexible metallic layer—iron wire netting, for instance—which is completely enclosed by the vitreous substance, and effectively protected against exterior influences, as rust, &c. The new glass is very strong and tough: it may be heated to a high degree, and then sprinkled with cold water without being materially damaged. The glass has been successfully applied to the manufacture of hollow glassware, it being particularly suitable for making vessels which have to be subjected to rough usage. Such vessels, if not too costly, should be most suitable for dark-room use, where the usual glass measure meets so often with disaster.

Stellar Magnitudes.—The question of star magnitudes is one of paramount importance in the great work of the universal star map, of which we have heard so much, and the method of ascertaining these magnitudes has given rise to much discussion, not to say controversy. In the *Astronomical Journal*, No. 269, the results of Mr. J. M. Schaeberle's work is given, and he has adopted a method differing considerably from those used by former observers. In his

plan the photographic magnitude of a star for any exposure time is expressed "as a fraction of the theoretical aperture which a standard star (*Polaris* in this case) would require to make the same impression on the plate in the same time." The particular form which the expression, as obtained from this investigation, assumes enables the observer, after having once adopted the photographic magnitude of the standard star, to determine the theoretical photographic magnitude of any other star without any reference at all to the visual magnitude.

Dark-room Measures.—In the direction of measures for dark-room work, there have, for some time past, been before the public these articles, constructed of white glass, with a slip of clear glass for noting the contents. Our own experience of them is not favourable. They certainly are not readily lost or lost sight of in the dim light of the room; but, unless the light be strong, it is not easy to measure the contents when pouring any liquid into them. The wire-glass vessels just mentioned would be very useful made jug shape and with coarse graduations. Clear white glass jugs graduated to half-pints are now purchasable, and are very useful for mixing batches of liquid, but in the average dark room are difficult to see when lying about, and are thus apt to get knocked and broken. A plan for treating measures, before described in these pages, consisting of painting a rim of white paint around them, might with advantage be carried out with these larger jugs. We would suggest a white rim round the outer margin or mouth, one round the middle of the jug, a complete coating of paint covering the whole bottom of the jug —all outside, of course. One photographer of our acquaintance uses the earthenware medicine measures for small quantities, as being more readily seen. It has been suggested by a well-known professional that white earthenware jugs, broad-mouthed, and marked inside like the small medicine glasses but only with half or quarter-pints, would be very valuable, and we are inclined to think with him, as, when pints and quarts of solutions are dealt with, the graduation would suffice, and the convenience and ready visibility of a white vessel with a handle need not be dilated upon.

CHLORIDE PRINTING-OUT PAPERS—COLLODION AND GELATINE.*

II.

Amongst the different makes of commercial gelatino-chloride paper there is found a considerable difference in keeping qualities; indeed, the same brands are often found to vary pretty materially in this respect, although not to the same extent. This result may be, and most likely is, due to variations in formula; but not wholly so, for the amount of moisture in the paper, or its state of dryness when first packed, forms perhaps the most important element in deciding its keeping qualities.

In the matter of permanence or capacity for retaining its quality unchanged, gelatino-chloride printing-out paper differs very materially from plates or, indeed, from any films on whatever support—glass, paper, or celluloid—that are intended for development. The latter contain only insoluble silver salts, being, if properly prepared, freed as perfectly as possible from all other matters of a soluble nature, including, of course, the decomposition salts formed in the process of emulsification. In the printing-out papers, however, there exist, in addition to the silver chloride and possibly other haloid, varying proportions of soluble salts of silver, free acid, as well as the whole of the soluble nitrates and citrates formed in the emulsion; and it is worthy of note that most of these, especially the citrates, are of a highly hygroscopic nature, and consequently extremely prone to cause the sensitive paper to absorb moisture, if the chance arises.

The necessity for thoroughly drying the paper in the first place, and of packing it in such a way as to secure it from damp afterwards, must then be patent; but, such precautions having been taken, there seems no reason why the gelatino-chloride papers should not keep their purity of tint unchanged for an indefinite period. I am led to this conclusion from having noticed frequently during the past few years that a gelatino-chloride emulsion, although containing a considerable excess of silver nitrate, never seems to discolour with keeping so long as it remains at a normal temperature, or, at least, is not frequently heated to much above 100° Fahr. It may become permanently fluid from decomposition of the gelatine, though even in this respect it is not so liable to change as an ordinary negative emulsion, but it will continue to exhibit for months the delicate bluish-white tint of the pure citro-chloride emulsion, or the more creamy-white conferred by some of the other organic silver salts, without the slightest degradation. I make the reservation I have done with regard to temperature because some of the organic silver salts, as well as the carbonate, are subject to spontaneous discolouration if the temperature be raised very few degrees above the melting point of the emulsion; indeed, it is almost impossible to keep an emulsion containing carbonate of silver liquid for any length of time without causing discolouration.

The fact of the keeping capacity of the emulsion itself is, of course, evidence in favour of the permanence of the paper, though it does not follow as a matter of necessity that the coated paper will keep as well as the emulsion itself. The latter, however it may be preserved in bulk, is, as a matter of course, protected and kept free from impurities and foul air, except perhaps on its surface. The body of the emulsion has only the action of its constituents upon one another to reckon upon, whereas, when it is spread upon paper, there are the possible impurities of the paper as well as atmospheric influences to be taken into account; and, looking at the hygroscopic character of the emulsion itself, the chances are greatly in favour of such accidental influences asserting themselves to their utmost power.

In preparing the emulsion, then, with a view to the keeping qualities of the coated paper, every care should be taken to avoid as far as possible those conditions that tend to give it a hygroscopic character. The requirements of the printing-out film make it impossible to altogether avoid the tendency; indeed, a certain amount of dampness, or rather a slight departure from a condition of absolute desiccation, appears to be a necessity in this as in some other printing processes. But, at least, the hygroscopic tendencies may be kept down as low as may be compatible with proper printing quality; and, in speaking of those, I refer also to other conditions, such as free silver, which, combined with the presence of moisture, lead to the deterioration of the sensitive film.

The gelatino-chloride emulsion for "printing out," as usually compounded, contains besides chloride of silver a certain proportion of citrate, free nitrate of silver, free citric acid, together with the products of the decomposition that goes on in emulsification, namely, alkaline nitrates, and, in many cases, alkaline citrates, the latter being used in too large a proportion. Now, of these, three at least possess decidedly hygroscopic tendencies, namely, the citric acid and alkaline citrates, as well as the soluble alkaline nitrates—at least, those usually present, those of ammonium and sodium. The nitrate of silver, by its presence and ready solubility, is always a danger to the keeping of the paper, while the citric acid exercises a very similar action to that already mentioned in treating of collodio-chloride, in causing the emulsion to become thick and ropy, and eventually to altogether lose its fluent properties. It should therefore be the endeavour to reduce the proportions of each of these to the lowest limit possible.

The ideal printing-out emulsion is usually supposed to consist of chloride of silver as the basis, with just such a proportion of silver citrate and nitrate as will confer vigour and colour, and citric acid to make it keep. The remaining soluble constituents are "necessary evils" which in the really "ideal" emulsion might be dispensed with if it were possible. Such an emulsion might possibly be formed by emulsifying precipitated citrate of silver and adding hydrochloric acid, to convert the necessary proportion of silver into chloride, citric acid being at the same time liberated, while it would only remain to add the requisite quantity of free nitrate of silver to complete the emulsion. I have, in fact, made such an emulsion, but unfortunately it possesses none of the qualities of colour that are required, hence we may steer clear of the theoretical idea.

Citrate of silver, we are told in the text books, is thrown down as a white precipitate on mixing solution of nitrate of silver and an alkaline citrate, from which it is assumed that citrate of silver is insoluble in water. How far this supposition is correct may be proved by mixing moderately strong solutions of nitrate of silver and citrate of potash, when it will be found that, though a dense white precipitate is formed

* Concluded from page 495.

at first, it is quickly dissolved on agitating the mixture, either partially or wholly, according to the degree of concentration. As a matter of fact, citrate of silver is freely soluble in water, especially when warm, and this partly accounts for the extreme translucency of citro-chloride emulsions, even when they contain a large proportion of silver. To prepare and collect citrate of silver by precipitation from aqueous solution is therefore practically out of the question. It may be obtained, though with much trouble, by precipitating alcoholic solutions; but the best plan consists in dissolving freshly precipitated oxide of silver by boiling in alcoholic solution of citric acid until the brown colour is entirely removed, decanting the clear liquid and washing the white precipitate with fresh alcohol. Citrate of silver, it may be said, is not discoloured by heat, for which reason I prefer it to any of the other organic salts of silver.

If any reader should desire to try the ideal plan of compounding the emulsion, that is to say, of starting with an emulsion containing only chloride and citrate of silver, the following will, I think, be the best way of doing it. First of all, prepare two separate emulsions, one of pure chloride, the other of pure citrate of silver. The first is easily made by Monckhoven's process, with carbonate of silver and hydrochloric acid; the second by emulsifying or dissolving citrate of silver, prepared as directed above, definite quantities of silver being used in each case. In this manner it will be possible to prepare, by mixing suitable proportions of each of the separate emulsions, one of citro-chloride, in which the quantities of the two silver salts bear any desired relation to one another, and it will thus be perfectly easy to study the effects produced by varying the proportions, while keeping clear of any complications brought about by the presence of any of the other salts usually existing in an emulsion prepared in the ordinary way.

Such an emulsion, in its simplicity, would be of little practical use for picture-making, but, as a means of studying the relative effects upon sensitiveness and vigour of image produced by increasing the proportions of one or other of the ingredients, it proves invaluable; and, by the subsequent addition of other of the materials already mentioned as necessary in the finished emulsion, the requisite proportions of the different salts for an emulsion of any kind could soon be arrived at with accuracy. Thus we know that gelatino-chloride paper can be prepared to suit either dense or thin negatives as may be required, to give dense, vigorous images, or the reverse; in fact, to suit any particular class of circumstances or any kind of work. These variations are mainly produced by modifying the proportions of the sensitive salts and the free silver to one another, and to the gelatine in which they are suspended, while the colour of the image, and its susceptibility to toning agents, depend more particularly on the soluble silver salt, and the presence of a certain proportion of moisture and acid. The keeping qualities of the emulsion and film are supposed to be dependent on the presence of free acid, and to some extent this may be the case; but on that point I shall have more to say later on.

With regard to free silver, it is usually supposed that an excess of nitrate of silver is a *sine quâ non*, but, heterodox though it may seem to say so, I am strongly of opinion that this is not the case. The function of the free or soluble silver is to form an organic compound with the gelatinous basis of the emulsion, a compound which plays the double part of giving vigour and colour to the image while the inorganic element gives sensitiveness. Bearing this in view, and also the fact of the solubility of citrate of silver in water or in solution of gelatine, it is not unreasonable to believe that the latter salt can be made to perform all the functions of free nitrate, while it is not so liable, by reason of its lower degree of solubility, to enter into dangerous combination, either in the emulsion itself or with any impurities in the paper or other support. True, we may expect the relative actions of the nitrate and citrate to differ at least in degree, and perhaps also somewhat in character, but in the main we may expect somewhat similar behaviour from them. In proof of this it is possible to make an emulsion in which there is not a particle of unconverted nitrate of silver, and which still yet prints in every way as well as any of the commercial papers now procurable.

The lower degree of solubility of the citrate of silver, which renders it less susceptible to the influence of accidental moisture, cannot fail to react on the uniformity and keeping qualities of the dried film, and on that account, if no other, it may be put forward as a recommendation to eschew the use of free silver altogether.

Turning to the question of free acid, here again I am constrained to express the opinion that for the purpose of increasing the keeping qualities of the film it is entirely unnecessary if the film be properly dried and protected from damp. I am not prepared to deny that, in case these conditions be neglected, a trace of free acid may be an improvement, my contention simply being that it is not a necessary improvement; while, as in another direction it exercises a deleterious action, it is as well to dispense with it if possible. I have never managed to make a sufficiently accurate and extended trial of the relative keeping qualities of acid and neutral papers, but I have in my possession at the present time emulsions that have never contained free acid, and one which is actually alkaline, and, though several months old—probably eight or nine—not one of them has shown the least sign of discolouration. This is surely evidence in favour of my contention that under proper conditions acid is necessary.

Many people are under the impression that, by adding citric acid to an emulsion containing free nitrate of silver, citrate of silver is formed; but such is not the case. It is difficult to say what is the precise state of affairs; but, though an effect is produced which slightly resembles that of actual citrate of silver, it is very certain that citrate is not formed. One result, however, of the addition of the citric acid is to cause the emulsion to be very thick and to set at a very low temperature, or at least to become so thick, unless a high temperature is maintained, as to render it impossible to spread it evenly upon either paper or glass. If, however, a few drops of dilute ammonia be added to such an emulsion, it at once becomes thinner or more fluent, while the film produced by it is proportionately denser or richer in colour. This is owing to the fact that the ammonia brings about the actual combination of the citric acid and silver, together with nitrate of ammonia as a by-product; the effect is, in fact, tantamount to the substitution of citrate of ammonia for citric acid in sensitising.

If an excess of ammonia be added, the emulsion not only becomes very fluid, but also almost transparent, owing to the silver chloride and citrate being dissolved by the ammonia, a very small quantity of which is necessary. Such an emulsion, though it gives a thin and perfectly transparent film on glass, renders rich, vigorous, and nice-coloured images on paper, and, as already stated, possesses good keeping qualities.

The hygroscopic matter forms an item of minor interest, since it is possible to give the desired or requisite degree of moisture to any kind of printing paper by means of a few minutes' exposure to our moist atmosphere. If, however, it be decided to make provision for the necessary moisture, it is far the better plan to let it take the form of one of the alkaline nitrates, which, while performing the duty under discussion, also acts favourably on the colour and printing quality of the emulsion, and has a less tendency to discolour the paper than have the alkaline citrates, or glycerine, sugar, and similar additions that have been proposed.

I am far from recommending the "ideal" plan of concocting the emulsion for practical purposes, for a satisfactory printing emulsion is far more easily prepared with nitrate of silver and a soluble chloride and citrate in the ordinary way when the precise proportions are arrived at. But what I particularly desire to point out is the fact that free silver, in the form of nitrate, and excess of acid, especially citric, are entirely unneeded. If an acid must be used in the free state, I should substitute acetic or nitric for the generally employed citric.

CONVENTION JOTTINGS.—VII.

A Run through Some of the Scotch Studios.

JOHN STUART (Buchanan-street, Glasgow).

OUR next visit was to our old friend, Mr. John Stuart, 120, Buchanan-street, Glasgow. The beginning of his career in the field of the art-science dates back to the days when photographers were fewer, and the demand for pictures was greater, because the producers were limited. Collodion was then in the ascendant. And in those days really one had to earn his bread by the sweat of his brow, when compared with the easy manipulations of to-day; but most of the early enthusiasts and workers have died out—only here and there we come upon one who holds his own, and works on in the photography of to-day

with as much zest as they did in that of former times. Mr. Stuart is one of those, and he stands in the position of having within himself the accumulated experience of all the changes from that time right on till now.

In the most fashionable street of the city Mr. Stuart's place is situated, and his showrooms are furnished and adapted for a high-class *clientèle*. Large pictures, highly finished, on draped easels; panel pictures, fitted in Mora stands, from small panel up to the largest size; platinum work, from cabinet up to life size, and every variety of modern picture will be found amongst the showroom decorations. Prominent amongst a vast variety of excellent work are the flashlight pictures from 15 × 12 down to cabinet size. We have had occasion to note this class of picture before, it having been a speciality of Mr. Stuart's for some time. After inspecting a much larger variety of subjects on this visit, we can but repeat what we have formerly stated, that Mr. Stuart's flashlight pictures, taking them all round, are amongst the very best we have ever seen. The "at-home" pictures, where the families, grouped in their drawing or dining-rooms, are arranged and posed with telling effect, and the exposure, which is instantaneous, with *f*-12 stop, is quite fully exposed and well lighted, without any of the black shadows that are so often to be seen in flashlight productions. The silver prints in the 12 × 10 flashlight pictures are of a warm brown tone, with an enamel surface, which tends to impart to them a liquid fine effect. Many of those we inspected were finished in platinum, and certainly we consider them the most artistic finish; at the same time we have no hesitation in saying that the enamel prints will still be the more popular with the general public.

But Mr. Stuart was saying that platinum-finished work in large heads and busts has taken the place, to a great extent, of the oil-painted portraits that have been so many years in favour, and that a quieter style of finish is rapidly gaining ground.

In his business carbon opals are much more in demand than the bromide opal, and he encourages this, as he feels that the carbon is really the much more permanent of the two.

He has been working all makes of the gelatine chloride paper, and for a considerable time he favoured the pink-tinted in preference to white. The pink he found very good and uniform for some time after its introduction, but latterly he has found it rather uneven in colour.

Enlargements of machinery of all kinds is one of the special departments of this business. We saw when there enlargements of engines, locomotives and others, beautiful, untouched, six feet in length: they were really astonishing pictures for clearness, sharpness, and general evenness of lighting all over. The objective used for enlarging these 6 feet pictures was a Zeiss Anastigmat of 15-inches focus.

We also saw some very perfect groups taken with the same maker's lenses, which show a remarkable depth of focus, extreme sharpness, and absolute rendering of detail. Many will have seen the Convention group Mr. Stuart made at Edinburgh, which, with all the disadvantages he encountered when taking it, still shows prominently these qualities we observed in the general work. We referred to this excellent group in our "Editorial Table" three weeks ago, and gave our opinion of its merits.

In his studio Mr. Stuart has Seavey backgrounds twenty feet long, specially painted for large-group pictures. Cameras, from cabinet up to 24 inch, are constantly in use for direct work.

We saw an American camera here for outdoor work, which takes a thirty-inch plate, with a revolving back. We believe that Mr. Stuart was the first to introduce the revolving back camera into this country, for, long after he had it in use, the English makers—one or two of them—took out patents for it as quite original, and still they did not make it as perfect as the American pattern, it possessing the advantages of taking a picture at any angle, the whole back being fitted in, and excluding light; whilst, with the English makes, the moment the back was turned from the horizontal or perpendicular, the corners of camera showed right, so that it could not be worked at an angle, but only upright or oblong. He has also a portrait studio down at Helensburgh, and in suitable premises erected for the purpose all his printing and finishing is done there. It is a very complete establishment, where, from the making of the dry plate to the finishing of the picture, everything is efficiently carried out.

Messrs. Turnbull & Sons (Jamaica-street, Glasgow).

Since we last visited this place, Mr. Robert Turnbull has passed away, in the very prime of life and usefulness. He was one of those genial souls that it was a pleasure to know, and many of those who went to the first Conventions were familiar with his bright and cheery face, and ever-helpful nature, for he took a great interest in the Conventions from the very first. He was one of the victims to the influenza epidemic at the beginning of this year, and the news of his death came upon us with quite a shock, for, when we saw him a short time before, he looked hale and hearty, and good for another twenty years.

The businesses are now under the proprietorship and management of Mr. Charles Turnbull, who, previous to Robert's death, conducted the Belfast business.

Now they have studios in Glasgow, Belfast, and Greenock.

The Glasgow studio is a very imposing structure, forming, as it does, the west corner of Jamaica-street and Argyle-street, having a run of 50 feet of frontage to Jamaica-street and 40 feet to Argyle-street. It is situated over the shops in the street. They have three flats, with an ornamental clock-tower at the junction of the streets at the top, which gives the whole place a bold and attractive finish.

The entrance way is at 10, Jamaica-street and is exclusive—no other parties entering by it to their business premises. The passage is fitted with an appropriate show of cases that always commands a crowd of sightseers. The stairway is broad, and the walls all the way up are made light, and bright, and airy-looking by being fitted with white enamel tiles. It is rather an exceptionally fine entrance way for such a crowded part of the city, where space means so much money.

On entering this place from the door on the landing, the air of business being done all round takes possession of us.

Opposite the doorway on entering is a polished counter, to which a young lady attends, seeing all who enter, and looking to the filling of the visitors' wants.

If to see Mr. C. Turnbull, you are shown to his private room. If a sitter, you are shown into one of the showrooms, and if for finished work—pictures that are to be supplied—the party is ushered into the delivery-room, which is a department by itself; as Mr. Turnbull says, "You know we find it a great convenience, for, 'if there are any complaints,' it is at the time of delivery they are made." Now you can understand how much easier and better to receive complaints and smooth matters out in a private apartment like this, rather than in an open place, such as any of the showrooms, where sitters or others are about, and where any little unpleasantness is going on, are so apt to catch up wrong impressions.

In Mr. C. Turnbull's private room telephones are fitted all round the walls. He has communication with the printing establishment at Toll Cross; he has also wires connected with every room in the studio. By this means he can have communication with any of his hands without leaving his room. Mr. Turnbull finds this arrangement invaluable, not only as a saver of time, but also a considerable saving of labour; there is no continual running up and down stairs, as there used to be, and the promptitude with which orders can be given and dispatched is very marked.

There are three studios worked on these premises, and the dark room in connexion with these is a special feature of the establishment. They are large and specially ventilated with Boyle's ventilators. They are well lighted by a combination of ruby and cathedral-green glass. The cathedral green was adopted by them when it was so much talked and written about, and from that time till now it has given them every satisfaction.

Another improvement we noted in these dark rooms is a gutter fixed under one large water tap, from which other small taps are fitted—ten or twelve of them—and set at equal distances, the gutter with these fittings running along the whole length of the sink. There is a square block fitted under each of these small taps, on which the negative is placed to wash. By this means they can have twelve negatives washing in running water at one time, and all supplied from the large tap, which flows into the gutter, and thence into the lesser taps. It does the work well and saves a considerable quantity of water.

Another new thing to us was observable at the entrance to the

dark room. The door of the dark room itself is set in a little square chamber, with doors opening at each side and in front, so that, in going into the dark room, one enters by one of these outer doors and shuts it, being then perfectly in the dark; the dark-room door can then be opened with impunity, no matter what delicate operations are being performed inside, without the cautions and callings that are usually resorted to in such a case, this arrangement rendering the operations inside free from any chance of extraneous light.

Large groups and cabinet pictures are what Mr. Turnbull makes the leading lines in his business. All this class of work goes out with enamel surfaces. The enamelling department is well worth seeing, the system and speed with which the pictures are turned out being marvellous. The waxed collodion-coated plates, 12 by 10 in size, are made, and then fitted into racks to dry, ready for use; these racks are built from the floor to the ceiling, and we saw them filled with hundreds of plates. In ordinary weather the plates keep well for two days; but, if it is very warm, there is a tendency for the collodion to peel off.

Mr. John Moran, the general manager at Messrs. Turnbull & Sons, was the gentleman who introduced and carried through the weekly half-holiday for the Glasgow studio hands—a movement that resulted in a great benefit to the employees, and one for which he deserves the best thanks of the employed. One thing must be said, both for the firm and its manager, that at all times the hands receive the most liberal consideration from them, and with the result that a change of hands in the place is rare.

In all kinds of artificial lighting, from a photographic point of view, Messrs. Turnbull have been ever to the front. The luxograph, magnesium ribbon and powder, and lastly, electricity, each have filled their day with them, and they are ever amongst the first to introduce anything new in the photographic world.

OPTICAL GLASS.

[Photographic Club.]

A MORE exact title for the paper would have been "Glass for Optical Purposes," although that is not a sufficiently precise definition, as all glass which we apply in order to see through it is, in a sense, "optical." But I should have to use a pretty longish term to define exactly what is meant by glass for optical purposes, and we may proceed to the more concrete part of our subject without leaving any doubt in our minds as to what we are talking about.

Antiquity of Optical Glass.

We know for a fact that optical glass was in existence before the Christian era; I do not mean to say that it was equal to Chance's dense flint, but, being used "optically," it was optical glass—at least, in its application. Claudius Ptolemy, the Alexandrian astronomer, living about the second century B.C., wrote a treatise on optics, refraction and reflection, and on lenses and mirrors. Copies of his works are said to exist in the Bodleian Library at Oxford, and in the Royal Library at Paris. We are, therefore, not talking about a new thing, either as regards lenses or with regard to "optical glass." Other works of a similar kind exist, one of the best known being that of Roger Bacon, who, in the thirteenth century, wrote his *Opus Majus*. He has, in fact, been looked upon by many as the inventor of the microscope, and the telescope too. We are not told where his "optical glass" came from.

You are all familiar with the story of how Galileo came upon the form of telescope which bears his name, but he does not possess the laurels alone, for we have it recorded that telescopes were made in the year 1600 by a Dutchman named James Metius, at Alkmaar, in Holland.

During all this time optical glass must have been procurable from somewhere. It is, however, very evident that the make of what we *now* understand by optical glass must be a modern thing, for it is evident that before Newton showed the different refrangibility of different parts of light, there could have been little room for such an establishment as the one now in existence at Jena, where glass can be had to order with a given index of refraction calculated beforehand to the third and fourth decimal for any part of the spectrum.

What is Optical Glass?

Glass was made, we know, something like 1600 years before the Christian era in Egypt, and, as it was soon ground into lenses, it must have been "optical." When glass becomes so pure that we can speak of its refractive indices, and of its spreading or dispersing the light in regular or even measurable ratio, we look upon it as optical. The crown and flint glasses so called, are those we use for optical purposes. Crown glass is a plate glass, or *vice versâ;* flint is a glass charged with lead. That for optical glass the finest and purest of materials must be used goes without saying. White sand is used, pearl ashes, borax, cobalt, manganese, and other ingredients, and as a matter of fact, hardly any glass is made without the addition of some pieces of broken glass of the same kind. Flint glass is also made of fine white sand, red lead, fine pearl ashes, nitre, arsenic, and manganese. Many of the modern optical glasses contain other additional substances, which I shall refer to later on. Flint glass was formerly made from flint ground up; but I understand it is not used now.

In England, Chance Brothers, of Birmingham, have for years produced some fine specimens of optical glass—notably, their heavy flints; and in France, Feill, of Paris, has made glasses in many instances exactly of the same character. In Germany nothing was produced on any large scale since the death of the great Frauenhofer in 1826—who made his own glass—until lately, when, after some experiments, carried on during a number of years, the scientific world was taken by storm with a series of glasses such as we had never had before, opening up new means of improved construction for all sorts of optical instruments, notably also the ones that will interest you most—the photographic objective.

It is very evident that, as far as the manufacture of optical glass on a truly scientific basis is concerned, there was much left to be desired by the state of things up to 1885 or 1886, and there was no means of eliminating certain errors of a chromatism entirely even form the finest instruments of the most renowned makers.

Several attempts had been made, notably in England, to bring about a more satisfactory state of things, and after the work of Frauenhofer had been cut short an Englishman, Harcourt, made experiments between 1834 and 1860, in all about 160 different pots, but he had not the technical assistance necessary; and, apart from some attempts which seemed to point in the right direction, he wasted much time in making glass containing titanium. This glass, which he principally made with a view of eliminating the secondary spectrum, did not answer, but it showed the possibility of getting rid of this secondary spectrum once the right material was found and applied in the right way.

Abbé and Schott's Experiments.

Professor Abbé is said to have come to the conclusion that the then existing state of things with regard to optical glass specially for microscopes could only be remedied by the creation of entirely new materials, and he gained this conviction after a visit to the exhibition of scientific apparatus in London in 1876. He communicated with Dr. Schott, who then lived in Hanover, and the idea of creating a new establishment for the production of improved optical glasses was accepted by both.

The principal object was to produce such glasses that would allow the elimination of the so-called secondary spectrum from the objectives, especially from the microscope, the instrument which suffered more than any other from this defect. Experiments were begun in 1881 and conducted on a small scale until 1883. From that date experiments on a large scale were undertaken, and with the help of some 60,000 marks contributed by the Prussian Government from the fund set apart for scientific research, many new kinds of glass were experimentally produced which, in combination with others of the known or of new kinds, would allow of combinations in which the chromatic or spherical aberration could, to a greater degree, be corrected, and the secondary spectrum be almost eliminated.

This is accomplished by improved crown and flint glass mostly with mixtures of boracic or phosphoric acids, while greater variety in the refractive and dispersing powers of the glass, was obtained by applying baryta, magnesia, and zinc oxides. Thus, up to now, something like eighty different kinds of glass have been put on the market, and experiments have extended to more than 1000 kinds of glass or compositions of glass.

The materials that have finally been adopted are several series of new glass, as the phosphate crowns, barium phosphate crowns, boro-silicate crown, barium silicate crown, &c.; borate flint, boro-silicate flint, a special silicate flint, and a light baryta flint.

Advantages of the New Glasses.

The great advantage which the constructing optician has gained by the establishment of this furnace is, that he can obtain any of the glasses enumerated in the catalogue always alike, and with increased precision for the measurements of the refractive indices. Nay, more, he may require a glass slightly different in refraction at one or the other part of the spectrum, and he can obtain it; but the

variety is in itself so great that for almost any special purpose a glass will be found that will answer. Moreover, formerly, every batch of glass turned out had to be examined in the spectrometer, and its refractive indices ascertained, while now they are precisely given for every pot, as well as the amount of dispersion for the principal parts of the spectrum, and the specific weight. As most of you know, the usual mode of specifying glass is by giving the refractive indices of the sodium line D (double line), and of the three hydrogen lines, C, F, and G. The measurements at Jena are, however, also made on the line A, the potassium double line, so that their measurements are made on five lines of the spectrum, A, C, D, F, G.

Their catalogue indicates for every kind of glass—the refractive index for D, the brightest part of the spectrum, the mean dispersion from C to F, following which is given the proportional or relative dispersion. The glasses are enumerated in order of this last factor, which allows at a glance a comparison of the refractive and dispersing values of glasses intended to be combined.

I found, some years back, that in some heavy flints made by Chance these indices agreed exactly with some glass of the same kind made by Feill, of Paris, so closely as to show the same figures up to the third decimal. If you had asked any of these makers to make two pots of glass exactly alike to that degree they could not have done it, or, at least, could not have guaranteed it to come out absolutely the same. Hence a new batch of glass had to be studied spectrometrically before much else could be done with it, and much of that labour is saved to the constructing optician now by the precision in which the Jena people specify their productions.

Such a profusion of new material is a great boon to the constructing optician who has been hampered by the insufficiency of the material at hand formerly because of the impossibility to fully achromatise with flints and crown glasses, or even with two flints combined, because of the disproportionate dispersion of most, if not of all, the heavy flints, as compared with that of crowns or of light flints. Many of the new glasses combine much better, and the result is that lenses can be constructed giving much flatter fields with the same angular apertures and better achromatism into the bargain. When the combined glasses allow the achromatising in three different parts (colours) of the spectrum, the so-called secondary spectrum is said to be eliminated, and the correction is for most purposes complete. This is of great importance in microscopic lenses, but for photographic lenses it is of less consideration.

Identity of Jena and English Glasses.

We find that at Jena they now produce exactly the same glass as the former glass made by Chance Bros., as, for instance, their No. 8, which we learn to be a "calcium silicate crown." There is another, No. 12, also corresponding to Chance's "soft crown." It is a "barium silicate crown." Their No. 58 again corresponds to Chance's extra dense flint. They call it "heavy silicate flint." And, finally, No. 40, another heavy silicate flint, corresponding to Chance's double extra dense flint. You will see that all these flints have a high index of refraction for the D region of the spectrum, such as 1·7174 for the least and 1·65 for the former.

You will see, by a perusal of the Abbé-Schott catalogue, that for photographic purposes mostly the silicate crowns or flints are useful, and also some of the baryta flints, most of which are colourless, or nearly so, while the *borate flints* are not to be employed for photographic purposes, on account of their being affected by the atmosphere. They will, however, be valuable for the microscope, where they can be protected by another kind of glass forming the outer lens or lenses.

Some Properties of the Jena Glasses.

The glasses which have proved to be of great value to the photographic optician and photographic purposes generally, are the baryta light flints, on account of their proportional high refraction, that is, a refraction of a considerable angle. This permits of lenses being ground with much flatter curves, inner and outer, and the result is a much flatter field obtained at the focal plane. As an instance I can mention Suter's new rapid aplanat D, which is made of such glass, and was, in fact, one of the first lenses manufactured out of this material, the curves of which are much less deep than any lens previously made of such intensity, viz., *f*-5·5. No. 2 u.s.

Voigtländer had made a lens of nearly the same angular aperture previously, but I do not believe they were kept going for any length of time, and the series have disappeared from their catalogue or are replaced by lenses of a newer construction. Suter had, in fact, made a lens previously of the same aperture (*f*-5·5, No. 2 u.s.), of which there were issued some few; but they were dropped in favour of the new construction which the Jena glass permitted, and a great gain in even illumination, rapidity, and flatness of field was the result, besides much more complete correction of chromatic aberration. Dallmeyer had also once produced a lens said to have had almost double the aperture of a rapid rectilinear, but it was not, I understand, issued on the market. I am, of course, speaking of cemented double combinations, not of triplets or lenses with separated back glasses.

These attempts of opticians to construct lenses with greater apertures, and so few faces only, were frustrated simply on account of the want of a suitable material. Now that the material is at hand, no difficulty exists, and in the hands of our able opticians plenty of these instruments, of excellent quality, are produced. The usual objection which was made as to using the new material, the one that it did not keep, has now pretty well been silenced, and English opticians, after some hesitation, have begun to use the material freely, and will no doubt produce excellent instruments from it.

The values of the several series of new glasses have been ably brought to the practical test by the Zeiss anastigmats, which are now largely manufactured and for which licence has been granted to a number of leading opticians, such as Voigtländer, Suter, and, in England, to Ross & Co. These lenses accomplish successfully what was, with the material previously at hand, tried repeatedly, but not with good results, viz., a lens of the rapid type, that is, with an aperture of *f*-8 and larger, which at the same time can be used as a wide-angle lens, and which, with the full aperture, already embraces a covering angle of about 60°, as is the case in the Series III.

Manufacture of the Glass.

With regard to the manufacture of the glass, it would be a vain attempt to write a description without a good set of illustrations; but some idea may be gained of the nature of the operations when we are told for instance, that the making of silicate glass will take close upon three weeks. The pot, or crucible, in which the glass is to be "cooked" is, after being well dried, heated during four or five days until it attains a red heat; it is then put into the oven where, as soon as it has reached the temperature of melting glass, a few pieces of glass of the kind to be made are put into it, and as they melt the inside of it is well glazed out with the molten glass.

The crucible is now filled with the sand and chemical substances that are to make the pot of glass to be produced. When this is thoroughly melted and worked into a homogeneous mass the crucible is brought to a greater heat still, which is supposed to thoroughly digest the pot of glass and drive all the air out of it, this lasts six to eight hours. The glass is now tried after being thoroughly stirred with a rod, and found homogeneous and free from air bubbles and clear. It is then tried on the blow-pipe. If the pot proves to be in good condition it is taken out of the oven by a crane, it may weigh some fifteen to twenty cwt., or about a ton. It is then left to stand and "gently simmer" so as to cool down a little, is then brought into another oven, in which a second crucible has undergone the preliminary warming process, and which is intended for the next pot of glass of the same or a slightly different composition. In this oven the glass is left about three days to cool; the contents harden up—dry up—as the melters say, and on "drying," or hardening, break up into a number of fragments.

The crucible is now broken up and the contents cleaned of any impurities. The clear transparent pieces are next subjected to the "setting" process. By this they are heated to about melting point, having been laid into moulds, where they adopt the desired forms of discs or slabs as required. This is done in a special oven, to which a cooling oven is attached. The cooling takes ten to twelve days, and the pieces are finally taken out, and two edges or faces are cut, so that through the polished surfaces—which, as you see in the samples, are always opposite to one another—the glass can be examined. The net result of usable glass amounts to about twenty per cent. of the quantity melted in a pot, and that is considered a good percentage.

This is the ordinary procedure for the bulk of glass intended for ordinary purposes. For special glass, such as large telescope object-glasses, a special process of cooling is employed, of which I can give you no specific information: but a circular of the firm of Shott sets out some points of examining discs of sizes up to, say, fourteen inches, and for which they have adopted what they call fine annealing, which consists in storing the glass in a vessel, the temperature of which can be accurately measured, and which is made to cool down at a very slow and uniform rate, and can be regulated according to requirements.

Testing the Glass.

Most of you may be acquainted with the mode of testing such discs or lenses by use of the Nicol prism. It consists of placing a lens or disc of glass, or a plate, between two polarising prisms, rotating the one until the light is polarised, and then observing the more or less regular figure of a cross on the disc; the regularity of the cross proves the homogeneousness of the glass. An irregular cross will be proof of tension in some parts of the disc.

It now remains only to put before you some of the samples that I have here to show, most of all of which are suited for photographic objectives, and all of which, I am told, may be looked upon as unaffected by the atmospheric influences. Most of these glasses are almost free from colour, and you will see that a number of them are light flints, which now take the place, in a great degree, of the former heavy flints, by which alone the high index of refraction necessary for some instruments could be obtained. This is, as I have shown, a great gain.

J. R. Gorz.

HARMONISING HARSH NEGATIVES.*

In this process, as in all others, great cleanliness is required, and the plate must have been thoroughly freed from hypo before proceeding to rehalogenise. If hypo or other chemicals be present, thin patches and dark spots will show; if there are grease spots or finger marks on the plate, irregular action will take place. It is best to take but one trial print from the negative, and exercise great care in doing so if rehalogenisation be thought needful. When operating on old negatives, I swab them gently with dilute ammonia to get rid of possible grease spots before beginning the process.

I will now pass around some prints from negatives before and after rehalogenisation, calling your attention to variations in and additions to the process necessary to secure different effects. I have, with one or two exceptions, printed in platinotype, as being less suited to harsh negatives than print out silver paper, and, in order to show what the process is capable of, most of the prints are from what would be considered hopelessly harsh negatives previous to treatment. I need scarcely say that I would not recommend that time should be spent, except for practice, upon any but negatives that are likely to give good results.

The prints marked A are from a portrait negative taken under very unfavourable circumstances. In the first print the deepest shadows are reversed, and the letterpress on the book is barely visible. The second print is from the negative after rehalogenisation. You will note that detail is visible in the darkest shadows, and that the light half-tone is just as discernible, the whole print being fairly soft. The third was printed after the book, and hands had been locally reduced. A little more detail is visible in them, but the reduction has not been evenly performed.

B is another portrait. You will see how dark it has been necessary to print the shadows before the detail in the face was strong enough. The second print is rather too dark, but you will note the absence of the aggressive brilliancy noticeable in the first.

C is from the negative of a waterfall lent to me by a member of our Society. In the first print the rocks are a mass of black, with one or two white leaves showing; the water is a mass of white broken only by a few dark streaks of shadow. The print, after rehalogenisation is, I think, quite a passable picture. It was, of course, impossible to obtain detail in the seething water, as the exposure given had been too long to secure that.

D and E are attempts to obtain passable prints from much-under-exposed negatives. Both seemed to be void of detail in the shadows, the only deposit of silver seemed to be in the sky, and its reflections through the trees from the water. The other portions of the negatives were badly fogged in forcing the development. D was cleared with hypo and ferricyanide, rehalogenised to soften extreme contrast sufficiently to permit of intensification intensified with pyro and silver, and badly obtained in the process. In attempting to clear this away the film frilled, and farther manipulation was impossible. A slight improvement is noticeable in the second print. The surface fog was cleared away from E with bichromate and sulphuric acid before the first print was taken. It was then rehalogenised, the sky being reduced to a mere yellow stain. When laid on a sheet of white paper, faint signs of detail were discernible in other parts of the plate. It was then five times intensified with mercury, followed by ferrous oxalate (Mr. Chapman Jones's method). The traces of halation round the tree tops visible in the first print, though apparently removed by rehalogenisation, were strengthened by intensification, but the shadow detail was much improved.

If the subject were worth the trouble, I believe it would be possible to remove the halation and slight traces of fog still remaining, and to obtain a soft clear print showing sufficient detail in the shadows.

F is a print of a pine-tree avenue from a negative lent to me. The topmost branches are invisible from halation, and the foliage in places has the appearance of being powdered with snow. The negative was rehalogenised, and I think you will admit that the second print shows these faults entirely removed.

G is a portrait group by one of our members. He performed the process of rehalogenisation from the formula I gave him. Although the first print is a warm-toned gelatino-chloride-of-silver one, which favours the harsh negative, I think the second print is platinotype shows the negative to have been much improved.

H is from a negative lent to me. It is a drawing-room seen through folding doors, taken to test a wide-angle lens. The lace curtains over the window opposite the lens are badly halated. I hoped that after rehalogenisation some detail would have been seen in the halated parts. Unfortunately the plate was poor in silver, and unable to register the extreme contrasts of light and shade. In the second print the window is a path of light grey, void of detail, although the other parts of the print are much improved. I thought I saw slight signs of detail in the window part of the negative, and carefully reduced it with bichromate and sulphuric acid in the hope of accentuating the shadows there, but the third print shows no improvement in that respect.

I is a view on the Brent, an attempt to show what might be done with a fairly good negative. The first print shows a blank sky. The landscape is, perhaps, a trifle wanting in brilliancy. As there were clouds showing in the negative, it was rehalogenised. In the second print the sky and clouds print out, but the whole print is poor and flat, the result of too compressed a scale. The negative was then intensified with pyro and silver, and the third print shows sufficient brilliancy more certainly than the first, and yet the sky, with its fleecy clouds, prints out. This is an instance of two scales being introduced into the composition, each of them being compressed slightly in the shadows, and the light half-tone rendered a little more fully.

In order to judge of what the process is capable of doing, it may be well to consider the action that takes place. If we were to strip the gelatine film forming the negative from the glass support, and reverse it so as to have what was originally the back of the plate outwards, and were able to remove the gelatine, leaving the silver image intact, we would find that image in the form of a low relief, the shadows being extremely thin and the high lights the thickness of the film. If now it were possible to take a shaving off the top of the image, removing only a portion of the lights and light half-tone, that light half-tone would be reduced in density, but would print as a flat grey tone without gradation. This is approximately what takes place when the development after rehalogenisation is stopped before the high lights are developed right through to the plate.

Fortunately, the simile does not hold good to the full extent. The developer in soaking downward does not act in rigid planes; before the shadow detail is fully developed the action has proceeded a little farther in the half-tone, and by the time the half-tone is thoroughly developed the highest lights are beginning to show traces of action at their points of greatest density. The result is that, if the development be then stopped in fixation, a thin film of silver is removed from the back of the negative thickest from the high lights, thinner from the half-tone, and not at all from the shadow detail. Some gradation of tone is therefore preserved in the light half-tone, but it must be borne in mind that this will not show the brilliancy it had in the original state of the negative. I believe that the composition of the developer will modify the action to a slight extent. By using a little bromide or reducing the quantity of ammonia the action will be retarded, and the developer will act more evenly through the thickness of the film. This is the method to be employed when the contrasts are great and the shadow detail fairly strong. When the negative is thin but still strong in contrast, the opposite method should be followed. The developer should act speedily, or, by the time the shadow detail is thoroughly developed, the high lights will also have been developed so far, that little or no improvement will have been effected.

You will see that, in asking you to give this process a trial, I do not recommend it as a panacea for all the ills that photographic negatives are heir to, nor do I suggest that, in all cases where it may prove useful, it will effect the whole of the cure. It must be used with judgment, and in many cases must be proceeded or followed by other treatment. I recommend it as probably the best way of lowering the light in a broad and even manner without affecting the shadows, thus introducing a second scale of light and shade into the negative.

Should the negative be too flat after treatment, it may be intensified either generally or locally to give the desired brilliancy. Or, if the negative, though flat, be still fairly dense all over, it may be rendered generally or locally.

The effect of intensification and reduction will be very different, though an unobservant eye might not distinguish between them, but the worker who desires to achieve certain results will discriminate in their use.

Intensification affects the shadows but slightly, the half-tone and lights being greatly strengthened, the result being analogous to the artist's method of rendering the lights in an approximation to the natural scale and compressing the shadows.

* Concluded from page 554.

Reduction will affect the lights to a trifling extent, while greatly altering the shadows. In the print the shadows will approach more nearly to nature, and the lights will remain flat.

The art side of the question forms no part of my subject. The application of these methods to our work in accordance with the canons of art will, I hope, be treated by a member of our Society, more capable than myself at no distant date.

I may, however, to illustrate my point, call your attention to a collodion negative (which has been lent to me) made from a steel-plate engraving. If we disregard the fact that it is composed of lines, and consider only the relative values of the light and shade, we will be struck, first, with the shortness of the register, the general flatness, if I may use the term; and, secondly, by the brilliancy of the local contrasts.

Were we to expose a thickly coated isochromatic plate upon such a scene, using a yellow screen, we would find upon development that, while the landscape portion of the negative would resemble to some extent the negative before you, the sky and its reflections in the water would, while showing strong local contrasts, be so opaque that it would be impossible to print them out; yet by rehalogenisation, followed by partial or general intensification or reduction, or by a judicious use of both, something approaching the desired result might be obtained.

As evidence of this, I will ask you to examine the negative from which the prints marked I were taken.

Without presuming to compare that negative to the collodion negative, either in artistic composition or technical excellence, yet I think that the relative values of the masses of light and shade and the local contrasts will be found to be somewhat similar.

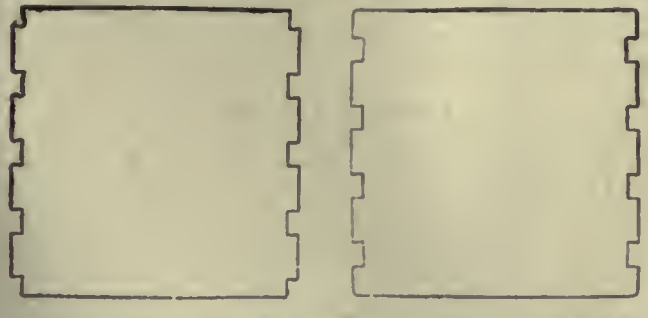
In conclusion, I desire to express my opinion that our best negatives from a technical point of view are those which most require, and will best repay, the time spent in trying by the various means in our power to make the tones and relative values of lights and shadows more nearly approach the results obtained by the draughtsman and the painter.

J. McIntosh.

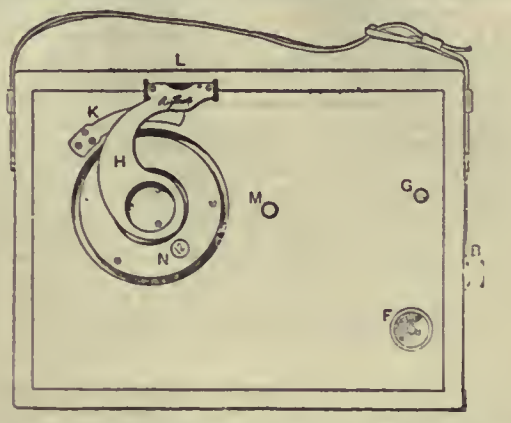
THE FRENA HAND CAMERA.

Since we noticed a few months ago the introduction of the film-carrying Frena Camera, Messrs. Beck have perfected certain improvements by which the efficiency of the instrument is still further increased. As supplementary to the notice in question, in which we showed a drawing of the exterior of the Frena, we are now enabled to give some details of its working and construction, more especially as we have had an opportunity of witnessing its manipulation in the hands of Mr. Conrad Beck, who is an expert in its use. By the reciprocating action of the lever on its side, Mr. Beck, in a singular brief period, transferred the forty films with which the Frena was charged from the vertical position in which they are exposed to the horizontal position in which, after exposure, they remain in the bottom of the camera ready for removal.

The films are notched on two edges, as shown in the subjoined cut,



and interposed between each film is an opaque card, also notched. This is also shown by a cut. But it will be observed that the notches are so arranged as to be antagonistic, those in the film corresponding with the projections in the card. Four pins project on each side at the focal plane, and on these rests the first film of the pack. By grasping the lever H on the side, and rotating it a certain length to a projecting check at M, the following actions take place:—The four pins on the focal plane at each side are moved aside opposite the notches in the film, which immediately drops, and on returning the lever to its former position, as in the cut, and in which it is retained by the spring K, the opaque card is also liberated and drops, leaving the second film of the series ready for exposure; and this goes on until the supply has all been exposed, which is shown by a registering index at N. A spirit level, L, on the top of the lever, shows when the frena is held accurately. But, as this lever influences the position of the film, the latter may be inclined in either direction, and it thus fulfils the condition of a swing-back. The



shutter is set by the milled-headed screw B on the front, and the exposure is made by pressing a button at F. A draw-bolt, G, has reference to the regulating of the duration of the exposure.

We have received an advance copy of the *Frena Handbook*, containing, in course of 160 pages and fourteen sections, full directions for working the camera, and many useful hints in photographic practice connected therewith.

The films are of a thickness sufficient to ensure their remaining quite flat when being exposed, and, the edges being notched by machinery, they are all necessarily identical in this respect.

ON THE SELECTION OF VIEWS.

II.

Most people, when examining a landscape picture, involuntarily desire to ascertain what exists beyond the foreground, scanning every little bit of distance or suggestion of it to satisfy themselves. The more suggestive a picture is, the greater interest it has for most people. The quality of attractiveness depends but little on the size of the picture, but is almost wholly dependent on the manner in which the subject is treated. Some of the most charming and artistic photographs produced have been small in size. It not unfrequently happens that a subject may show to better advantage in one size than another, or one shape than another. If a subject is intended for enlargement by the optical lantern or otherwise, it should be judged rather of itself than on the focussing screen, as the reduction in size is sometimes apt to mislead. One important point in landscape work is not to have it too crowded, and another to have the lights and shadows well massed. A number of lights distributed pretty equally over a picture causes a spotty effect, which always interferes with its pictorial value, by distracting the eye and inducing an unrestfulness that is apt to be fatiguing. The study of Mr. H. P. Robinson's writings on picture-making cannot fail to be of assistance to the beginner, showing him the why and the wherefore of certain forms of composition. In selecting the view, objects should be so arranged that the linear and aerial perspective assist each other, carrying the eye continuously from foreground to distance. One or two special points of interest are preferable to a great number, and the lines of the subject should be so arranged as to lead up to these special points. The beginner may ask, How are they to lead up to it? The reply is, by studying the forms of the objects and the disposition of the light and shade, so that the eye ranges from one to another, finally resting on the point it is desired to make of importance. For instance, suppose a pathway over fields, hidden here and there by undulations in the ground, trees, or what-not, with a cottage in the distance, or perhaps nothing more than a chimney-stack above the trees, the eye involuntarily follows the track to the distant object, which at once becomes the point of interest, and the hidden portions of the path are imagined; but that is quite sufficient to supply the mind with the idea of its continuity, aided by the disposition of lines of hedges, fencing, or whatever it may be, towards the same point. So it may be said of the windings of a river, appearing and disappearing amongst the trees and banks. We see it at hand, maybe a rushing, impetuous torrent, to be traced as a broken silver line in the hazy distance, till it finally disappears. The linear and aerial perspective assist each other in giving a true impression of space.

In the examination of a view as to its suitability for photography, I find it a good plan to nearly close the eyes until no object is particularly distinct, which permits a better judgment being exercised as to the value of the light and shade alone, irrespective of detail. One may also more easily estimate the effect of the proportion of foreground to distance and middle distance in this manner. The Thames side in summer time; it is an animated pretty scene, but, unless particular care is taken to secure a proper foreground, the river's opposite banks and landscape beyond will be little more than unimportant-looking strips in the photograph. In such a view we must get some fairly large object near the foreground; a boat with sails set is one of the best, or a well-arranged group on the bank fairly near the camera, with the water for a background, is also satisfactory. Trees, in this case, are only available now and then, unless from a bend in the pathway, as lenses of only very moderate angle are suitable. In almost all cases where the landscape forms parallel strips, the camera should be so adjusted that some object partially hides or breaks them up. In nature colour will, in most cases, prevent the monotony of form being particularly noticeable; but when, as in the photograph, this is done away with, the arrangement becomes unpleasant.

The greatest number of landscapes are better for having some large or important mass of material on one side or other of the foreground, and the general form more or less repeated in the middle distance. With respect to the introduction of figures, the view, in the first place, should be selected and examined on the focussing screen. It will then be seen where figures will help out the composition, it is a mistake to merely put in a figure for the sake of a figure unless it improve the picture; in fact, many photographs would be considerably improved if the figures were left out altogether; at the same time, there is no denying that a suitable figure, or group, well placed, is a great addition to almost any landscape. However, they must not be placed too near, or in too great a number, or the landscape becomes a figure subject, with a landscape background, which parts with most of its interest in consequence. In searching for subjects, valleys are more prolific in suitable bits than higher ground; the side of a stream is frequently the best part of a district. It is always a good plan to look about in near proximity to water, for often, when other parts have been drawn blank, the water side will provide pictures.

Water itself is eminently suited for photography, either for itself or as an accessory. It possesses the inestimable quality of variety; the glassy pool, the foaming torrent, or the breaking wave have all their lovers. In this connexion it may be remarked that a perfectly still surface, reflecting everything like a mirror, is never satisfactory in any but stereoscopic work, where we get apparent solidity and depth; it is therefore advisable to disturb the water just prior to making an exposure. A very slight movement will break up the reflections, and that is all that is required.

Bridges, ruins, green lanes, and marshy districts will, in a flat country, usually supply plenty of subject. With respect to flat, marshy districts, good cloud effects may frequently have conjunction with them; the marshy ground, with irregular patches of water, lends itself exceedingly well to cloud effect, as well, or better, than the seaside. In photographing ruined buildings or other architectural subjects, one of the most important matters is to choose a proper time of day, so that the shadows are as effective as possible. With the sun shining directly behind the camera no good results need be expected; the image may look fairly well on the focussing screen, and the negative be technically perfect, but in the finished picture the improper lighting will be glaringly manifest, and such that no dodging in the printing or in the negative will remedy. All architectural subjects depend very much on proper lighting for effect, as much so as portraits; neglect, consequently, in this particular results in unsatisfactory work. Hilly and mountainous places, as Wales, Devonshire, and some of the midlands, are probably as prolific in suitable bits as most counties; the difficulty is not where to choose, but what to choose. The best plan is to thoroughly prospect the place, making notes of any particular view, and seeing it at different times of the day, so that the best light may be selected, or some accessory or other introduced that is not always present, if it will help the effect. For instance, a lane scene beautiful in itself might be vastly improved if a rustic cart and horse, or something of the kind that would harmonise with the scene, could be introduced. It is generally possible to manage matters of this sort without much trouble, but generally necessitates a previous acquaintance with the spot, so that you may know exactly what you require, for it is rather tedious waiting for that particular something to turn up in out-of-the-way places, like scores in Devonshire and Wales. The more unfrequented, the better it is for photography; and this applies to places other than Devon and Wales. Age, neglect, and decay, rough, home-made contrivances, such as are frequently found in outlying rural districts, are the things that have charms for the picture-maker, if not for others.

Boats and shipping are always picturesque, and on that account will continue to be favourites with photographers. Vessels left on the beach by the receding tide and discharging their cargo often supply very good subjects. Anchors and rusty chains are useful in the foreground. There are few pictures more attractive than a good maritime or river subject well treated. There are few places in this country where pictures cannot be had, providing they are sought for by *trained* eyesight; and my advice to all photographers is to look well about their own neighbourhoods, if they have not already done so, and they will probably be surprised at the number of pictures they will discover hitherto passed by unnoticed. EDWARD DUNMORE.

Our Editorial Table.

LANTERN OBJECTIVES.

BY JAS. SWIFT & SON.

IN anticipation of the lantern season, now close upon us, Messrs. Swift & Son, Tottenham Court-road, have introduced a series of objectives, all alike in principle, but of different focal powers, those submitted to us being respectively of four, five and six inches equivalent focus, although the series extends to ten inches, each in succession being one inch longer than the other. They have a large angular aperture, and hence project a slide under circumstauces of great illumination, which is aided by the fact of their being constructed of colourless Jena glass. One of five inches equivalent focus, which we critically examined, has an aperture of *f*·2·85.

Lantern objectives, especially those of foreign make, have often very long tubes, doubtless with a view to covering sharply, which they do not usually do; but in those before us the tubes or mounts are comparatively short, one result of this being that there is great equality in the illumination of the disc, owing to the large volume of light that that is transmitted obliquely.

Finding, upon trial with a test slide made from an engraving that the field was flat, we set about discovering the means employed for effecting this with a mount which, as stated, was somewhat short. We found, what we have elsewhere described as an essential condition, that there was an excess of negative spherical aberration in the back combination, which balanced the positive aberration of the front combination, one of great power in proportion to its diameter. It may here be stated that the diameter of the back combination exceeds that of the front.

In the mounting we observe that the teeth in the focussing rack are cut obliquely to its length, a feature now present in many of our best microscopes. This ensures smooth working by the pinion, and prevents "back-lash," or what microscopists term "loss of time" when focussing. Lanternists will readily grasp the fact that with the shorter of the objectives under notice, that of four inches equivalent focus, a large disc is obtained when there is no great distance between the lantern and the screen. This often proves of great advantage, especially in parlour entertainments or otherwise confined positions.

CONVENTION PICTURES.

MR. A. WERNER (Werner & Son, Dublin), who had left for the nonce the studio portrait camera, in the use of which he is such a proficient, in favour of the landscape camera, proves that he is quite as much at home in the use of the one as of the other by sending some charming pictorial mementoes of his activity during the outings now so pleasantly associated with the Convention in Edinburgh.

The views received embrace scenes in St. Andrews, Almond Dell, Cramond, and on the banks of Loch Katrine. They are printed in platinum, and are prized as reminiscences of a good time during a happy week.

STUDIES. BY F. M. SUTCLIFFE.

G. W. Wilson & Co., Aberdeen.

MANY of the admirable studies by Mr. F. M. Sutcliffe, with which exhibition visitors have in late years become familiar, are now being reproduced and issued by Messrs. G. W. Wilson & Co., the prints being made by the carbon process. The firm has recently submitted two specimen prints of the series to us (the subject of one being the widely known "Water Rats") which, alike as examples of the process and of Mr. Sutcliffe's art, are technically and artistically admirable.

PATENTS COMPLETED.

A Simplified Form of Magnesium Lamp.

No. 17,586. Percy Ellis, The Manor House, Wallington, Surrey. *August 13, 1892.*

My invention relates to a simple construction of a lamp for burning magnesium ribbon or wire, or other similar material, whereby the ribbon may be kept burning by being pushed forward by the thumb and first finger of the hand holding the lamp, entirely without the use of rollers or mechanism.

It consists of a small spirit or other suitable lamp resting on a stand, so that the flame will ignite the ribbon as it is pushed through a small hole or slit in the reflector behind the lamp. The reflector is held secure in position behind the lamp, and a handle is fixed to the whole, at a suitable angle to the reflector, and of such a shape that it can be easily grasped with one hand, three fingers below, and the thumb and first finger above, the handle.

The ribbon which is to be burnt is held between the thumb and first finger, and from thence passes under an indiarubber band through the slit in the reflector, and then into the flame of the lamp, the supply of ribbon being kept up by shifting the wire forwards with the thumb and first finger.

The claim is:—A lamp for burning magnesium or other suitable ribbon or wire, having a handle as described, whereby the flame can be kept fed by the action of the thumb and first finger pushing forward the ribbon in the manner described.

[We are interested in knowing whether, if one pushes the magnesium ribbon through the flame of the spirit lamp by "finger and thumb" instead of by the clockwork employed in the Solomon & Grant lamp, otherwise similar to the above, will Mr. Ellis consider it an infringement of his patent?—Ed.]

Improved Means for Obtaining Photographic Portraits.

No. 17,967. George Bagnall Bradshaw, Beech House, 45, Oxford-road, Altrincham, Cheshire.—*August 13, 1892.*

Take an ordinary piece of statuary and place it on any convenient stand before a black or coloured background, and vignette the head from the body, leaving as much neck as possible. I vignette off the head from the body in the following manner by using an ordinary vignetting screen before the lens or in the camera, by preference in the camera if the background is a black one, and between the lens and the object to be vignetted if the background is white or coloured.

Any photographic process can be used for procuring a negative of the image. By preference I use ordinary photographic dry plates, and take the impression in the usual manner. I make a series of negatives from statuary, both busts, three-quarter and full length, in any position I may think advisable. Should my sitter wish a photograph of their head placed on either bust, three-quarter or full-length statuary, I place my sitter before a black or same tinted background as the statuary was photographed against, and take a photographic impression of the head, vignetting away the bodies by using an ordinary vignetting screen either in the camera or between the lens and sitter as before stated. I take the impression on any sensitive photographic film. I use celluloid films, and vignette the head from the body just a little below the chin, so that it will register on the neck of the statuary negative, which can be done by placing the negative of statuary selected on the focussing screen of the camera, and so adjusting the camera that the neck of sitter and that of the statuary negative shall be exactly the same size, or sketches can be made from the statuary negatives on any convenient transparent substance, and used instead of the negatives for the purpose of getting the neck of sitter in register. When I have obtained my photographic impression of the head I wish to place on statuary, I take the transparent film, and after adjusting it on the statuary negative, and retouching out all imperfections, proceed to print, through both negatives, by any of the ordinary photographic printing processes. I also mask or cover the face of any image, or life subject, or painting, or drawing, so as this part will appear almost bare glass on the negative, which I make in the usual manner; I then photograph the face I wish to place on the aforesaid negative by placing my sitter behind an opaque background, by preference black velvet, in which there is cut an opening just sufficiently large to show as much of the face as I require; I take the impression on any transparent film, registering the head in the manner previously stated; I place this film on the negative, adjusting the face over the part that is almost bare glass, and after retouching out all imperfections, proceed to print, through both negatives, in the usual manner.

I also make negatives of ladies, gentlemen, and children, in any position I may think advisable, and place other heads on their bodies by aforesaid process.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—1. That this is the only true method of placing the head of one subject upon the body of another, and printing from same without showing any join. 2. And of placing any face on any photograph of picture, statuary, or life subject, and of making same, when printed, appear as if the photograph was a direct picture and not a combination. 3. And that by this process ladies and gentlemen can be saved the trouble of dressing for their pictures, as all we will require will be a photograph of their heads and necks, and sitters can select the position or dress they would like to appear in on the finished picture from our stock of negatives or prints.

[But how about the "statuary" photographs of this nature that were common several years ago? Will Mr. Bradshaw kindly point out in what respect his method differs from that formerly employed?—Ed.]

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
September 12 ...	Darlington	Trevelyan Hotel, Darlington.
,, 12 ...	Dundee Amateur	Asso. Studio, Nethergate, Dundee.
,, 12 ...	North Middlesex	Jubilee Hall, Hornsey-road, N.
,, 13 ...	Derby	Smith's Restaurant, Victoria-st.
,, 13 ...	Manchester Amateur	Lecture Hall, Athenæum.
,, 13 ...	Stockton	Masonic Court, High-street.
,, 14 ...	Leicester and Leicestershire	Mayor's Parlour, Old Town Hall.
,, 14 ...	Munster	School of Art, Nelson-place, Cork.
,, 14 ...	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
,, 14 ...	Reading	
,, 14 ...	Stockport	Mechanics' Institute, Stockport.
,, 15 ...	Brixton and Clapham	Gresham Hall, Brixton.
,, 15 ...	Greenock	Museum Com. Room, Kelly-street.
,, 15 ...	London and Provincial	Champion Hotel, 15, Aldersgate-st.
,, 15 ...	Oldham	The Lyceum, Union-st., Oldham.
,, 16 ...	Cardiff	
,, 16 ...	Holborn	
,, 16 ...	Leamington	Trinity Church Room, Morton-st.
,, 16 ...	Maidstone	"The Palace," Maidstone.
,, 16 ...	Richmond	Greyhound Hotel, Richmond.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

September 1.—Mr. P. Everitt in the chair.

Mr. S. Ashby was elected a member.

Amidol.

Mr. A. Cowan in reference to amidol confirmed Mr. J. A. Sinclair's experience with it in having developed twelve negatives in the same solution. He (Mr. Cowan) considered amidol a very good developer indeed. His twelve negatives each occupied the same time in development and were of equal density. The two ounces of developer which he had brought with him were quite clear. He had tried it with paper, and it did not stain.

Questions.

The following question from the box was read:—"The edition of *Photography* to-day (September 1) threatens retaliation, with compound interest, upon the London and Provincial Photographic Association for having been the means of correcting some of the misleading directions published in that journal. Ought the Society to take any action in the matter?"

The Chairman asked whether it was worth while to take any notice of the matter?

It was understood that the question would be brought before the members at a future meeting.

Question No. 2: "Why must absolute and not methylated alcohol be used to dissolve cyanine for preparing the bath when orthochromatising?"

Mr. R. Beckett said the Britannia Works Company had recommended absolute alcohol. He had got cyanine to dissolve in the ordinary methylated alcohol.

Mr. T. Bolas said there would be no harm in the employment of the ordinary methylated spirit if "finish" were not present.

Question No. 3: "Is there a process for copying tracings which gives a green positive image upon a light green ground?"

Mr. G. W. Atkins said a good many copies of tracings passed through his hands which were evidently of a photographic character, and wished to know how they were produced.

Mr. Bolas said that green positives could be produced by the primuline process, which was described in The British Journal of Photography (see page 657 of the volume for 1890).

The meeting concluded after deciding upon competitions for copying and enlarging.

Hackney Photographic Society.—August 30, 1892, Mr. R. Beckett presiding.—Questions:—Does the carbonate of soda reduce the P.O.P. in fixing more than sulpho-cyanide? Reply: slightly.—How long will sulphate of iron keep? Reply: Almost indefinitely if bottle be full and well stoppered, and acidified with sulphuric acid. When the solution is clear and green it is *ferrous*, and aids the image-making, but when brown it is hydrated oxide of iron or *ferric*

and destroys the image. Discussion on the best mountant for the P.O.P. when polished was then continued. Mr. Reynolds advised gelatine, *quite* boil it, then allow to get nearly cold, though liquid, and use. If it be applied hot it will skin over. Mr. Harversen uses "aristotype paste" with good result. It was suggested that thin cartridge was as effective in keeping on the gloss as the ordinary waterproof blacking. Mr. Hudson showed a magazine containing twenty-four plates—one shutter. Place in changing bag, and take out plate from one side and put away in other. Members' work shown from Messrs. Dean, Gosling, Parfitt, Pollard, and Sodeau. A Daguerreotype was shown; method of producing it explained by the Chairman. Mr. SODEAU then gave a paper on *Dark-room Illumination*. Explaining the theory of light and dispersion, showed the use of the spectrescope. In its absence an efficient test is by using a piece of blue glass. If white light seen through these combined is affected by other tints, it shows the colour to be more or less faulty. Exposures of ½, 1, 2, and 5 minutes were uniformly made under the same conditions, viz., light about 1 candle power at 1 foot. Developer same. (*a*) Argand gas lamp, red chimney—result, transmits red orange, little yellow. Plate (1) Paget's 50, 1 minute. Image just visible. (2) Edwards' isochromatic medium, ½ minute, visible. More fog with isochromatic at ½ minute than Paget's 50 at 5 minutes. (*b*) Red glass, transmits red orange, and just a trace of yellow. (1) Paget's 50, 5 minutes. No effect. (2) Edwards' isochromatic medium, 1 minute, just visible—same as red chimney on Paget's. Altered burner to a Bray's, Paget's just showed at 1 minute. (*c*) Aurine (30 grains to 1 ounce of collodion), original burner, transmits red orange and a fair amount of yellow. Paget's 50, just visible in ½ minute. More fog than red chimney, but is counterbalanced by being more comfortable to work with, and can see with much less light than red.

Putney Photographic Society.—By the courtesy of the Director, members of this Society visited the Royal Gardens at Kew on Saturday last, and photographed in the various houses which are only open for the purpose until twelve o'clock, when the general public are admitted. After twelve the time was spent in photographing out of doors, and, as these beautiful gardens abound with objects of scientific and artistic interest, time went only too rapidly. The weather was favourable for photography, being generally fine, with a good diffused light, giving plenty of time for the shadows without destroying the high lights. While we were busy in the houses the weather was dull, with occasional showers of rain. This, in conjunction with the use of isochromatic plates, no doubt accounts for the entire absence of halation from the negatives. In the houses a wide-angle lens, say, of focal length less than or equal to length of plate, will be found very useful. The houses lend themselves particularly to effective stereoscopic photography, of which advantage was duly taken by one of the members. As a hint to intending visitors, it may be mentioned that, working with *f*-20 and Edwards' instantaneous isochromatic plates, an exposure of twenty seconds was found to be about correct in the houses, the resulting negatives being full of detail in lights and shadows and with fine gradation. Round the lower lake plenty of good views may be found, including snap-shots at the water-fowl of various kinds. These are readily brought into position by the judicious distribution of crumbs of bread; the wise photographer will provide himself accordingly.

South Manchester Photographic Society.—August 29, Mr. J. Wilkinson in the chair.—Several of the members, in response to the request on the circular, had brought exhibits of holiday work, consisting of negatives, prints, &c. Mr. Reid showed several lantern slides taken from negatives exposed in a Miller's hand camera. The Chairman brought two Sandell plates, one exposed for two seconds, the other twenty seconds with *f*-16, and developed with pyro, bromide, and ammonia. In the discussion that followed it was the opinion of the meeting that the longer-exposed one was the best, although very slight difference could be perceived between the two.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

PHOTOGRAPHY BY RULE.

To the EDITOR.

SIR,—I much regret if anything in my letter published in last week's JOURNAL betrays a style of controversy in any way unworthy of me, as Mr. Bedding opines; nothing is further from my intention than to say that which may reasonably offend or misrepresent. To set the example of forbearance, I admit that it is natural to suspect that commercial bias enters into my estimate of the paper I have criticised. I hope and believe, however, that such is not the case.

Mr. Bedding is content, he says, to waive his belief in the value of trial and error, as applied to exposure, if I will place the contrary beliefs in the scale against the work done by the vast majority of professionals and amateurs who do not employ aids to exposure.

If I attempt to meet Mr. Bedding on these lines, my reply must be that it is impossible accurately to gauge the work of this vast majority, as I am not ubiquitous, nor will they show me their failures. On the other hand, his paper would disappear bodily.

Whenever an attempt is made to raise a science from the qualitative stage to the quantitative, the same objection may be made; and, when in photography somebody initiates the quantitative element, it is injudicious to say that this has not been needed hitherto, and to decry the attempt.

I have not overlooked the reference to shutters, nor am I unaware of the existence of one-solution developers. I confined my attention to the "apparently inexhaustible supply of inventive genius," having for sole object the reduction of exposure and development to pure rule and system. These epithets are not, as far as I can see, applicable to shutters and one-solution developers; nay, according to Mr. Bedding, it is "mechanical aids to exposure" (*i.e.*, time and instantaneous shutters) which have called forth this "inexhaustible supply" of genius which he considers misplaced. Again, *vide* Jabez Hughes and Hardwich, one-solution developers were more numerous in olden times than they are now, so they are barred out from the category to which I have alluded; they are merely proposed as alternative methods of development.

I am asked if I maintain that no sources of error exist in the instruments of which I have spoken favourably. I reply, they are correct in principle as far as they go, and Mr. Bedding's "impeachment of the constancy of the factors taken into account in the systems" is no examination of the principles of these instruments. The principles of the instruments assume the *variability* of the factors with which they deal, not the constancy of them. An attempt is made, from a tolerably accurate knowledge of the present value of these factors, to deduce a proximately correct exposure, *and this they succeed in doing*. Further considerations with which the instruments *do not* deal often render the result still more exact. The point in dispute seems to be that, although exhaustive knowledge of all the factors is unattainable, I hold that we can extract a large amount of help from such approximate knowledge as we have, while Mr. Bedding considers this approximate knowledge quite inadequate to be of real assistance. I am surely correct in considering the formulæ issued with a plate as the result of the maker's judgment, in which case the "differences of opinion" to which Mr. Bedding refers are conflicting judgments whenever they involve error. (Word-splitting is not confined to my side of the discussion.)

Mr. Bedding says that, if a man cannot master the difficulties of exposure by the aid of his own brains, he will not do it at all, yet considers an inference which I have drawn, viz., that a youth who does not succeed as well as a companion who uses such aids must deplore his own want of brains and give the thing up, as unfair. Having Mr. Bedding's assurance that this seemingly obvious conclusion is unwarranted, I willingly withdraw it, and ask what the youth must do? Blunder on, or adopt the other's method?

I fear Mr. Bedding will have to take up my challenge for a good negative on an unknown plate himself, or it will remain unaccepted. By unknown I mean one of whose speed he has no idea. In such case as he names, he evidently would rather have the trade description than nothing. I would prefer something more definite than the row of xx . . . . x, unknown quantities, which figure as the only clue to the speed of the plates, or the vague direction, "Average exposure, one second."

I have recently handled two plates, one requiring about thirty times the exposure of the other. Is it not advisable to know which is which; and, if so, better still to know the actual speed of each? No. Look at the focussing screen, and find out by trial and error, unless I misunderstand Mr. Bedding's doctrine.

I am told I am unfortunate and rash in looking upon aids to exposure as the focus of others' experience, but no hint is given *why* that is so. Remembering what has been said about "mere empiricism" and "falsely-lying inspired formulæ," I think the matter should not be handled so guardedly, in terms so equivocal.

What I mean by "pinches and handfuls of light, advocated in preference to calculated quantities," can hardly be a matter of doubt to any one; the phrase carries its own interpretation.

As I have asserted that Mr. Bedding's paper does not touch any single principle of the instrument which I have defended, I will shortly state what these principles are. They are that the time of exposure varies (1) inversely as the actinic power of the light; (2) inversely as the speed of the plate; (3) inversely as the area of aperture of the diaphragm; (4) directly as the focal length of the lens.

Not one of these principles can be called in question, nor the combined result of all four. No individual judgment can modify, without introducing error, the verdict of the instrument as far as these principles are concerned.

But judgment is of value in dealing with extraneous conditions with which the instrument does not directly deal, such as the question of securing the representation of one of two violently contrasting terms to the sacrifice of truth of the other; *e.g.*, the securing of clouds at the expense of shadow details, or the reverse. Such considerations are noted by the issuers of the instruments, and the list is open to extension, providing ample scope for experience to assert its value. But, by limiting itself to its own proper sphere, judgment grows apace, though I leave open the question whether error will be eliminated to such an extent that the knowledge of how to correct it in development will become lost as a thing of the past. The mere hint of such a contingency following the use of the instruments in question speaks much in their favour. For my part, would that the art of doctoring photographic plates and human bodies alike fell into desuetude through the absence of need.

I cannot rightly gauge the photographer who prefers to make bad exposures now and then for the excuse it affords him of dodging the development afterwards. If such there be, they can still ride their peculiar hobby as often as they feel inclined.

My attention has just been called to a paper, signed W. K. Burton, in the JOURNAL for September 15, 1882 entitled "A Table of Exposures."

He says: "It is usual, in speaking of the exposure of plates, to say that the conditions are so very various that it is impossible to give any clue to the time which it is necessary to allow light to act, and that a knowledge of it can only be gained by experience. This, I believe, is not the case. It is true that *some* experience must be gained at the first start, but this experience may with advantage be supplemented by that which has been gleaned by others. . . . . The table proved so useful to many friends on their first taking up the art-science, that it has appeared to me that at least a few of your readers might derive benefit from the publication of it."

Can Professor Burton's table be fairly described as the "falsely inspired formula" of "mere empiricism?" Nobody dare say so, and I submit that it is unjust and incorrect to despise the authors of exposure tables and instruments because Mr. Bedding does not *know* them to be practical photographers! Has he tried to discover whether they are? Can he tell us of one who is not?

I would once more assure the student that there are better times in store for him than his predecessors have had, if he will but make intelligent use of their experience and painstaking research.—I am, yours, &c.,

Arts Club, Manchester, September 3, 1892. R. C. PHILLIPS.

"THE DECAY OF PROFESSIONAL PHOTOGRAPHY."

To the EDITOR.

SIR,—The sensible letter written by so clever and experienced a photographer as Mr. A. Wilson is known to be cannot fail to secure the unqualified approval of every professional photographer of repute. It was time, indeed, that the voice of a professional of standing should be heard on the question. In endorsing every item of Mr. Wilson's letter, whose experience is precisely similar to my own, and, I think, that of a host of other professionals, I should like to emphasise the passage of Mr. Wilson's letter where he says, "If I want a really useful assistant, I have to train one myself, or procure one from the Continent." The apprenticeship in vogue there is really responsible for the acknowledged superiority of assistants who, in most cases, have a good practical knowledge of the whole business, whilst they are generally experts in one or more branches of the same. Moreover, as a rule, they are not the spoiled young gentlemen who now often consent to be apprenticed.

It is all very well for chemists and other scientists, who very laudably have turned their attention to photography, to talk wisely about what the profession is, or ought to be, but are not professionals more fit to judge? Let these be heard, and I think it will be found, whilst all agree that the possession of a good chemical and scientific knowledge is essential, *that alone* is quite inadequate without a few years' apprenticeship. If it were not so, how is it that so very few of those gentlemen of science have built up reputations as professional photographers? As a matter of fact, a first-class artist is never found to be an equal expert at science, and, although there is no reason why a photographer should not be a clever scientist also, the artistic element must predominate, but the commercial part claims no less attention. At any rate, to achieve success, the aspirant, in my opinion, should be a good artist, with a sound knowledge of the business portion. The nature of the photographic art demands that the really good photographer should be sufficiently well acquainted with the science underlying it, for which reason it necessarily is included in the apprenticeship tuition. How is it possible, then, that a... i is art, commercial aspect, science, &c., can be learnt away from the studio? By all means let the tiro supplement his knowledge by giving the professors of the Polytechnic, Technical Institute, and others a turn, but he is in a better condition to profit by their discourse when he has served his apprenticeship. He will certainly be less likely to turn up his nose at the latter, should he not strictly adhere to the highly scientific language of the lecture-room.—I am, yours, &c. J. HUBERT.

September 6, 1892.

To the EDITOR.

SIR,—In the midst of much pressure on my time, I cannot refrain from endorsing the common-sense remarks written in your last week's issue by Mr. A. W. Wilson.

Technical class education is excellent, so far as it goes, but that is not very far in these latter days. Art education becomes of more and more necessity. Collateral with his science studies, the student should be connected with an art school, and obtain a solidly ground-in knowledge of anatomy, modelling, and lighting, and shading generally, and free-hand drawing. This is of ever-increasing importance, and no single minute so spent will fail to be afterwards remunerative.

When the pupil has attained a sound proficiency in these directions, if he will recognise that he is not yet an experienced photographer, as he may fondly imagine, but just in a position to commence his *real* education by serving some years in a good practical studio, then we might be easy about the future supply of photographers worthy of their name, and also both the artistic and financial prospects of our profession.

There is no decay of professional photography among men who are equal to supplying the satisfactory demand for, and appreciation of, better work engendered by the generally advanced art tastes at present manifest, but there is an inundation of fly-blown intruders, who insult the profession by imagining that they have it "at their finger ends" because they have been glamoured by their few months' results with a cheap camera and a convenient back yard, where, by the potent aid of a blanket background and materials generally on the button-pressing principle, they have created abortions of their suffering friends.

Photography has, doubtless, some nasty lessons in store for such people as seek to enter her ranks in this left-handed manner, and think they have discovered "a royal road to fame.' They, in conjunction with the solely theoretically accomplished pupil, will, I question, not find room to look longingly at stone-breaking as a more comfortable and withal profitable employment.

But who will bemoan that photography can thus assert her right to respect and legitimate devotion? Not I, for one. If it were only the puny, sickly process, some of the dabblers in it would lead us to conceive, judging by their results, then, indeed, might we expect its ultimate downfall.

There is no question, too, that the old conservative photographer nowadays finds his possibly technically good, but artistically doubtful, work received with increasing coldness as æsthetic taste advances. But here also the short-coming must be recognised as his own. It all points to the same end. Let photography cease to be regarded as a superficial plaything, to be less or more accidentally acquired; let its students, having suitable natural tastes, be educated up to its scientific, artistic, and practical possibilities, and I will warrant we need have no feelings of alarm for the process.—I am, yours, &c., LYDDELL SAWYER.

September 5, 1892.

UNIFORM SIZE OF PLATES.

To the EDITOR.

SIR,—Miss Barnes, in her paper read before the Birmingham Photographic Society, touches upon the question of "uniform sizes of plates"—"Our (American) size, notably for hand cameras, is 5 × 4."

I have always held that 5 × 4 should be the basis of our system; that is to say, it should be our quarter-plate, or 10 × 8 our whole-plate. Hand cameras of 5 × 4 are as readily carried and operated with as our present quarter-plates, and may serve for all the purposes of the quarter-plate as well, if not better, while an additional and exclusive lantern-slide camera of three and a quarter would be more to the purpose for that particular branch of work.

The question, however, arises, what would be the best "half-plate" between the sizes of 10 × 8 or 5 × 4? In America, the 8 × 5 size is used, being the exact half of 10 × 8, but it entails carrying a camera nearly as large as the present whole-plate, while the surface of plate is barely three-quarters of it. But if we take half an inch off its length, making it seven and a half, and add half an inch to its width, bringing it to five and a half, we have a plate of handy and pleasing dimensions, *slightly over* the half area of our (10 × 8) whole-plate, big enough to satisfy the angle of our vision as a picture, and entailing a weight of apparatus light enough to be carried by almost any one. Moreover, it may form the basis of a further international size, as it is the only one in inches which agrees with an acceptable size in centimetres, viz., 14 × 19.—I am, yours, &c.,

19, *Buckingham-street, Strand, London, W.C.*, J. R. GORZ.

September 5, 1892.

PROPOSED SOCIETY FOR STRATFORD.

To the EDITOR.

SIR,—I know of no photographic club in the districts of Stratford and Forest Gate, and if any of your readers who reside near this way would like to have one and join it, I should be glad if they will communicate with me on the subject.—I am, yours, &c., S. L. WILTON.

Longmore Villa, Romford-road, Stratford, E., September 5, 1892.

THE ACID SILVER BATH.

To the EDITOR.

SIR,—From your correspondent's—T. W. Edwards's—letter, I think there can be no doubt his trouble is caused by sensitising albumenised paper on a very acid silver bath. Some samples of paper turn a neutral solution of silver acid very quickly, and the addition of kaolin, with a little carbonate of soda, is quite inadequate to correct this tendency. Test the silver solution with blue litmus paper, and add strong liq. ammoniæ until blue litmus paper ceases to turn red. Repeat this whenever necessary, and be careful to *keep* the bath neutral, as, unless this is done, any change of toning bath will be of no avail.—I am, yours, &c.,

PHOTOGRAPH REGISTERED:

James Grey, East Stonehouse, Devon.—*Photograph of Naval Barracks, Devonport.*

T. E. B., A. F. M., T. E. G., W. MORRIS, and others.—Received; in our next.

JAS. A. FORREST.—Many thanks; we will reserve your interesting letter and enclosure.

A. G. R.—The prints, judging by the very small strips you send us, are by the gelatino-chloride process.

PRINTER.—See article in the present issue. You, like many others, confound one process with another which is quite different.

"ACCURATE EXPOSURES."—The correspondent who writes us on this subject has neither completed his letter nor furnished his name and address.

N A FOG.—So far as we know there is no other reliable method of ascertaining whether your plates have been light-struck except by exposure and development.

PANEL.—1. Yes, there are "panel lenses" on the market, which will work at a speed of one second in the studio, provided the light and other conditions be suitable. 2. It increases detail.

J. DAVIS.—When the bichloride of mercury is applied it always darkens the film at first, but when its action is continued the image is whitened. You have been in too much of a hurry for the result.

PATENT.—If the invention is patented you have no right to infringe it, even if you make the apparatus yourself, and for your own exclusive use. You have no right to another person's property, and this the patented invention is.

R. HILL.—Large carbon prints, on thick paper, are best mounted with starch paste, and we are surprised that you have failed with it. Make the starch very thick, and apply it with a good-size piece of sponge, breaking up the lumps as it is rubbed on.

A. CORNWELL.—About the cheapest background you can have, and it will answer your requirements quite well, is a large piece of brown paper. This material may be had four feet six, or five feet wide, and in any length. It is sold under the name of carpet paper.

A. B. says: "I am an assistant, living in the house. My agreement was to be paid weekly. I have, however, let it run on eight or nine weeks. If my employer were to become insolvent, can I legally claim the full amount?"—Yes. In case of insolvency your arrears of salary would rank as a preferential claim against the estate.

AMATEUR (Strood) says: "I am about to erect a temporary studio in the garden. Will thick Willesden paper do for the roof where glass is not required? As I am shortly removing, I do not wish to go to much expense in the matter."—Willesden paper will answer quite well. Zinc is cheap just now, and that would be equally suitable and not expensive.

A. W. says: "When coating glass plates with gelatine for enamelling prints, a number of small holes or 'pits' form. I am told they are caused by fatty matter in the gelatine. Is this correct?"—The "pitting" of gelatine is generally ascribed to grease, but some maintain that it is not the cause. However, no more generally satisfactory explanation has yet been given.

S. L.—We are surprised that any manufacturer, even a foreign one, who had executed your order wrongly should dispose of the mounts, with your name upon them, to any other photographer. No respectable English house would have done so. The only remedy we can see that you have is against the purchaser, under the Trade Marks Act, for supplying pictures purporting to be of your production.

L. E. CLARK.—There is no reason why the report should not be correct. We have known more than one instance of an accident happening through the condenser of a solar camera being exposed when out of use. On one occasion considerable damage was done to the apparatus and the fittings of the enlarging room, and, but for the timely arrival of the fire brigade, the entire building would have been destroyed.

F. C. (Glos.)—1. If the photograph is not copyright, it may be copied for sale. 2. It will depend much upon circumstances. In this matter a solicitor versed in copyright law will be able to give a more reliable opinion than we can. 3. If the owner of the negative has a copyright in it he can certainly stop the sale of pirated copies and recover costs from the vendor. No doubt the owner of the negative will permit you to reproduce the portrait in the paper for a consideration. As it is his property, he is entitled to remuneration.

F. K. writes: "Can you, through your paper, give me some idea as to the cause of marks on enclosed photograph? It is mounted with starch, and the marks do not show till after the prints are burnished. A little help will oblige."—The marks are due to the mounts. The material with which the cards are surfaced is soluble in water; consequently, when the starched print is applied, the colour is partially dissolved. If one of the mounts be moistened with the tongue, the colour can be easily rubbed off with the finger.

R. DIMBERLINE.—You do not say what aspect the studio has, or whether you wish to work from both ends. Presuming you only desire to work from one end, fifteen or sixteen feet of glass will be sufficient for that width of studio, commencing, say, four feet six or five feet from the background end.

G. FENTOM says:—"In the dark room I have great difficulty in finding the right side of matt-surface bromide paper, and have lost many prints from putting the wrong side on the negative. Is there any way of judging the right side with certainty?"—If the point of the thumb and finger be slightly moistened with saliva, and an extreme corner of the paper be pressed between them, the coated side will be found slightly adherent. It will also be noted that the edges of the paper have a slight tendency to curl inwards. This is always on the coated side.

JAMES BENTLEY writes: "Would you kindly inform me what mountant is suitable for gelatino-chloride prints that have a glazed surface. I have used several, including shellac dissolved in spirit, but I get distinct marks and loss of glaze where the mountant has been applied."—There will be a certain loss of gloss whenever an aqueous mountant is used, if it be applied after the print is taken from the glass. If the mount be attached while the print is on the glass, and still moist, and then allowed to dry, the full gloss will be retained. A waterproof paper is sold by many of the dealers for attaching to the back of the print when it is squeegeed on the glass; then, after stripping off, the picture can be mounted with starch or anything else, still retaining the glaze.

REAPER says: "I wish to build a studio for business purposes in the garden in front of my house. On mentioning this to one of my neigbours he said it would not be allowed, as the town surveyor had power to prevent. I have bought a long lease of the premises, and the studio would not stop off any one's light. Will you tell me if any one can prevent me doing what I like on my own property, provided I injure no one else's?"—Without knowing all the conditions it would be impossible to give an opinion. The local authorities in every town have their bye-laws, and these, in the case of buildings, are usually stringent. As a rule, they have the right to reject or modify any plans submitted to them, and this they would certainly do if they considered the proposed erection would deteriorate the surrounding property. Better consult the town surveyor in the first instance.

OLD SCOTTY.—1. We have not tried the hand camera alluded to, but it is said to be good. 2. A lens working at *f*-8 is quick enough for street subjects with moderately rapid plates. 3. In saying that the "chromotype process" was practically obsolete, we were referring to the original process of Lambert. This formed the subject of a patent which has long since expired. For the process a special tissue was supplied, but only to licensees. Eventually it was found that the pigments of which it was compounded, or some of them, were fugitive with exposure to light. Its manufacture has now, we believe, been discontinued, or it is only made to order. The process itself (that is, with ordinary tissues), which consists in developing the carbon image on collodionised glass, and afterwards transferring to paper, is still practised somewhat extensively. You cannot do better than give the process a trial. The tissue is now supplied in small quantities, ready sensitised, which much simplifies the working. If you require variety you might try the gelatino-chloride printing-out paper.

ERRATUM.—In the second paragraph of Mr. Dunmore's letter on "Decolourising Shellac Varnish" in the JOURNAL of last week, "a glass flask of four ounces" should read "a glass flask of *forty* ounces."

PHOTOGRAPHIC CLUB.—September 14, *Transparency Printing*. 21, *Photographic Fallacies*. Outing, Saturday next, September 10, Greenwich, under the leadership of Mr. A. Haddon. Boat from Old Swan Pier at two o'clock.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—September 15. Out-door Meeting to Gilsland, Nawarth, and Lanercast. Train leaves Central Station, Newcastle, at a quarter past eight a.m. for Gilsland Station. M. Auty, leader.

THE WEATHER AND PHOTOGRAPHIC SOCIETIES' OUTINGS.—We received the following report of the outing of a photographic society last Saturday:—"Seventeen present; a soaking wet day; plates exposed, 0. Programme:—Drinks, smokes, nap, dinner, return."

NEW MONTHLY SUPPLEMENT.

IMPORTANT NOTICE.—*With the* JOURNAL *of Friday, October 7 next, and on the first Friday of each succeeding month from October to March inclusive, we shall issue a special gratis supplement, devoted to the interests of the makers and users of the optical lantern, in which every phase of the subject will be treated by the ablest authorities. This step, which has been in contemplation for a considerable period, is necessitated by the increasing popularity of the lantern in its numerous applications, scientific and domestic.*

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1689. Vol. XXXIX.—SEPTEMBER 16, 1892.

ON DRY MOUNTING.

Involved in the novelty and excitement of experiment, or the reduction of experiment to practice—new developers, new modes of development, new papers, new cameras—the claims of old processes and methods, whatever their value, have little chance of being heard a second time when once their advantages and methods have been clearly set forth and adopted, or allowed to fall into oblivion, as the case may be. The adoption of the almost universal sulphite of soda might be looked upon as an exception to this dictum; but it really is not; for, though its advantages were plainly set forth by its lamented inventor, the late Mr. H. B. Berkeley, and it was left absolutely unnoticed for a time, its ultimate popularisation was only due to repeated and entirely disinterested efforts on his part to force it into notice. Among other valuable methods of work hitherto fated to semi-oblivion is that known as "dry mounting." It is not said for a moment that this mode of mounting has no followers; there are many photographers in the country who adopt it, and have nothing but praise to say of it. We unhesitatingly state that if once it be given a fair trial (using a little of Opie's "medium") there is little chance of any other mode of mounting being again made use of for any except the larger sizes of work. There are, of course, difficulties attendant upon the inceptive operations, but in this dry mounting is no exception to a general rule. If the query be put, "What are the advantages of dry mounting?" it can be concisely replied to. By its aid prints can be finished off ready to deliver far more quickly than by the older plan. When finished, they are better done, and the mounts do not buckle or curve. A dozen cabinet or larger prints so treated will lie in a heap as flat as a pack of cards, and will preserve their flatness though left exposed singly to the air. Even with the most accurate and careful mounting by the old method, the curl—slight sometimes, oftener, perhaps, considerable—will make its appearance even with a heap of mounted pictures, while single ones almost invariably assume a twisted or bent aspect, the contrast in the general appearance of finish between the two being most marked. Then, again, when, as occasion sometimes necessitates, a print has to be removed from its mount, it is done with far greater ease with one dry than wet mounted.

It may be asked, "What are the disadvantages of the method?" and to this we may reply that they are two in number and insignificant. Firstly, to dry mount with greatest ease two people have to be at the work together, though it can readily be done by one. Secondly, it is very difficult to dry mount neatly upon enamelled cards. When a mount of this kind is once damped a portion of the surface gloss is removed, and a smeared appearance given to the mount through the uneven surface so produced. Further, it occasionally happens that, either from the damping sponge or a setting off from the surface of the rolling press plate, a little enamel is transferred to the face of the print, and is very difficult of removal. These are all the disadvantages likely to be encountered.

As to how to set about dry mounting, the process, though it has been described often enough in these pages, will bear repetition in connexion with this attempted quasi-resuscitation. The prints are first coated with mountant in the usual way, and when the latter is dry they are ready to place on the card as follows: The card itself is damped by a moist sponge being passed over it. The print is then laid in its place, and being kept there with the fingers, the thumb being under the card, it is laid upon the plate of the ordinary rolling press, and at once passed through, when the mounting is complete, and the mounted picture ready to send out on the spot.

This is the bare outline of the method; a few details may be filled in. There is no need to dry the prints before pasting; they may be taken in a heap from the washing water and pasted after draining the water away. It is, however, better to lay them evenly on one another before pasting. Any of the ordinary mounting materials may be used—starch, gelatine, gum, &c. It must be laid on as evenly as possible, as, otherwise, streaks may appear. Some photographers paste before cutting, while others who trim their prints previous to toning necessarily paste after cutting. The advantage of the former method is that there is no fear of any smear from the mountant appearing at the edge of the print, and also no danger of the print being imperfectly pasted at the extreme edge, that being the place where there is greatest possibility of an insufficient application of mountant.

The advantages of rapidity of mounting will be seen at a glance. A print may be taken straight from the washing water, the surface water blotted off, the print pasted, dried by the fire, cut, and mounted, and be ready for delivery in less than a quarter of an hour. It will, however, be found in practice that spontaneous drying in a warm atmosphere is better than drying before a fire or over gas, as it is our experience that the latter way tends to produce cockled prints, which are much more difficult to place in position and send through the press. We have only to repeat that, given a fair trial, the process will commend itself to every one who endeavours when attempting it to make it succeed.

ACCURACY OF PHOTOGRAPHIC APPARATUS.

Although it is customary to regard the path of the modern amateur photographer as infinitely smooth compared with that along which his predecessor of fifteen or twenty years ago had to travel, there are occasional small obstacles he has to encounter, which perhaps are all the more difficult to bear with an equanimity of mind since they are not of his own creation. For example, it is the occasional worker who more than his professional *confrère* is perturbed and inconvenienced by the inaccurate manner in which commercial glass plates are cut, since in all probability he is not the possessor of a diamond, which would enable him to readily remove the offending protuberances, and hence the plates have to be wasted. As a rule, we know that in all commercial dry-plate factories such care is observed in the examination of the coated plates for general and particular defects that we are surprised more attention is not bestowed on accuracy of cut.

Many occasional photographers will sympathise with a correspondent of a few weeks back, in his suggestion that the small turn back pins, which in the majority of dark slides are used to hold the opaque division between the plates *in situ*, should be made so that they could be more easily moved. Too often each pin is so affixed to the sides of the slides that a knife, or some other sharp implement, has to be requisitioned to move it, the finger tips being quite inadequate for the purpose. This is one of those small details which, if carefully attended to, save an amateur considerable trouble, and possibly labour, in substituting something more effective.

We have spoken of the inaccuracy of cut of many glass plates, and it may therefore read rather paradoxical if we now venture to complain of a too great exactitude on the part of many makers of photographic cameras; but it is nevertheless true that for practical purposes it is possible to have too great an accuracy in those respects, particularly in the dimensions of the slide rebates. Very often we have observed that these measurements are so precise, that if an accurately cut plate be inserted in the slide after exposure it is only to be removed by the friendly aid of the penknife, or even in some instances the application of pressure to the film side of the plate, a by no means pleasant resort if one is developing, and the fingers are wet or damp with the solutions. Here we have indicated two common sources of what we shall term dark-room annoyances, which a little forethought on the part of the makers would obviate.

Makers of the highest class of apparatus are, we believe, in the habit of subjecting their productions to a practical examination with a view to ascertaining whether they are in such a state of efficiency in details as to warrant their being placed in the purchaser's hands for immediate use. This is as it should be. Of late years, however, the long-sustained demand for cheaper articles has led to the dissemination of a great deal of photographic apparatus in which, by the necessities of commerce, the manufacturers are unable to afford the time to practically test it, or to bestow so much care upon those and other details we have referred to, the onus of so doing being therefore cast on the purchaser, for whom it cannot be agreeable to have the ordinary difficulties of photography supplemented by others for which nothing but a slenderness of purse makes him responsible.

Another and a most frequent source of annoyance in the use of the camera out of doors is the singular habit of many makers fitting the dark slide to the back of the camera with apparently as much precision as possible, so that, as we have noticed with very many cameras that have passed through our hands, the slide (where it partly or wholly slides instead of fitting in) can only be pushed home with difficulty. For such ideal precision there is not the slightest necessity, and the consequence of it is, as we have frequently noticed, that when the view is focussed, and the slide is being pushed into the camera, it is only by the greatest adroitness that the camera, stand, and all are not displaced from their position. A tolerably free movement is not only desirable but necessary for comfortable outdoor work. In the case of the camera and slides having got damp, the evil of a too accurate fit is, of course, intensely aggravated.

These are some of the many extraneous difficulties which the aspirant has often to encounter in the pursuit of his new-found hobby, which it should surely be prudent of the manufacturers to remove; but there are others to which we may advert another time. It is annoying and troublesome enough for old and experienced photographers to have to cope with these and similar obstacles to successful work; to the occasional worker it is often the cause of failure.

M. Lippmann's Colour Method.—Mr. Hermann Krone in Wiedemann's *Annalen*, gives an account of some further experiments connected with the photography of spectra in their natural colours by Lippmann's method. He finds that the correct rendering of the various colours depends upon a high degree of accuracy in the proportions of the finely divided silver haloid and the colour sensitiser, as also upon the temperature of drying, the exposure, and the development. If the essential conditions are not fulfilled, it may happen that yellow appears in the place of red, or that green exhibits a direct transition into violet, the blue being unrepresented. The result also depends upon the amount of water contained in the film, as influencing its thickness, and in the case of the solar spectrum upon the altitude of the sun. With a very long exposure the infra-red appears as a dark purple, and the ultra-violet as a yellowish-pink lavender colour. Mr. Krone has also succeeded in producing coloured photographs without Lippmann's mercury mirror. He simply covers the film with black velvet, exposing, as Lippmann did, through the glass. In this case, the reflection from the inner surfaces of the glass takes the place of that from the mercury. The exposure has to be considerably prolonged, and the colours towards the red end are less pure; but the blue, violet, and ultra-violet are quite as brilliant and well defined as in the mercury process.

Reversed Negatives on Gelatine Plates.—According to our report, it was stated at a meeting of the London and Provincial Photographic Association the other night, that reversed negatives for photo-mechanical purposes are produced, by one process-worker by taking advantage of the circumstance that an ordinary gelatine plate in contact with a negative will, if exposed long enough, yield on development a negative instead of a positive. We were not previously aware that this phenomenon was put to any practical use. It appears, however, that success is only assured with certain makers' plates.

The Growth of New Societies.—We always welcome the advent of new societies as evidence that photography is still in a state of expansion, but that feeling is subject to the qualification that in the district selected there is legitimate scope and demand for the establishment of such an association. This, however, we have regretted to notice during the last year or so, has not invariably been the case, several societies having been started, or attempted to be started, almost next door to ground already occupied. As one good big society, in our opinion, stands a better chance of doing serviceable photographic work than two small ones, we hope that unattached photographers will, where possible, join existing organizations in preference to starting societies which are not imperatively called for.

Fugitive Pigments.—It is very clear that, although some photographers consider the permanence of their pictures as a matter of importance, they pay little or no attention to the stability of the colours with which they are finished. We were forcibly reminded of this a few days back when seeing at a suburban railway station a carbon picture—an enlargement—that had evidently been exposed there for some time. From its appearance we judge that the print had changed somewhat, though very little, from the fading of the pigment employed to give warmth to the colour. The picture had been finished in monochrome, and the artist, in matching the tint, had used a fugitive colour—probably a cochineal lake or crimson. By the action of light this colour had been quite discharged, so that every stroke of the brush, or stipple, showed as a decided black line or dot in strong contrast with the delicate tones of the picture. We have frequently referred to the fugitiveness of the pigments now in use for general printing purposes, particularly in photo-mechanical processes, notably in collotype. At one of the stations on the same line of railway as the above picture is to be seen an advertisement, the capitals in which were printed in scarlet ink, the rest in black. The scarlet has been discharged, and what was once Gracechurch Street now reads "racechurch treet" at a distance of a yard. The reading of some of the other parts is equally as ludicrous.

Serious Explosion.—An accident, by which four persons lost their lives, occurred in Paris on Saturday last. As a similar accident is liable to occur to any one employing collodion, the circumstance requires a passing comment. It appears that the wife of an enameller of photographs, in handling a large vessel containing collodion, accidentally let it fall. The vapour from it mixed with the atmosphere, and reaching a light exploded, shattering the house and also setting it on fire. It may not be known to all the users of collodion that the vapour from ether, and alcohol also, when mixed with a certain proportion of air forms an explosive compound like a mixture of coal gas and air. Therefore, whenever a bottle of collodion is broken, all lights, even those at a distance, should at once be extinguished, and the apartment freely ventilated. As the vapour of ether is much heavier than the atmosphere, the lights below the level of the spilt collodion should receive attention before those above. If we mistake not, Mr. Valentine Blanchard, many years ago, met with a similar accident to that in Paris, in which he was seriously hurt and his premises destroyed, but, providentially, no lives were lost.

Pyroxyline.—Collodion is still largely used in photography, and, as most persons are aware, its character is mainly dependent upon the pyroxyline used. Some samples, for example, will yield as viscid a solution with two grains to the ounce of solvents as others will with six or eight. Now, it is manifest that, where a film of a given thickness is required, the more pyroxyline that can be got into a workable solution the better it will be. The film will be quicker dried, and, as less solvents are used, there will be considerable saving of cost. The specification of a patent for improvements in the manufacture of pyroxyline has just been published. By this improvement the patentee states that a collodion can be made containing from twenty to twenty-five per cent. of pyroxyline. The method is this: The cellulose is subjected to a temperature of from 150° to 170° for from four to eight hours. It is then immersed in the acid while still hot. By this treatment the inventor says the cellulose is modified by the heat attacking the foreign and incrusting matters so as to prepare for their destruction in the acid. As the photographic properties of collodion are largely influenced by the character of the pyroxyline, it will be interesting to see how this particular kind will behave in the collodio-bromide and the collodio-chloride processes, also in the wet-collodion, process which is still extensively used for some purposes.

Surreptitious Photographs.—According to the report in a daily contemporary, two Americans have been detected at Quebec taking sketches and photographs of the engines and guns of one of the British cruisers lying in that port. The report adds that the sketches as well as the photographs were seized and destroyed, and that the two alleged spies have disappeared. Now that detective cameras are disguised in so many different ways, and concealed in waistcoats, hats, neckscarves, &c., and tele-photo lenses practically ignore distance, the authorities will have to be exceedingly vigilant if they wish to prevent their armaments and fortifications being photographed surreptitiously.

Professor Hale's Sun Photographs.—At the late meeting of the American Association for the Advancement of Science, Mr. George E. Hale, of Chicago, read a paper on *The Spectroheliograph of the Kenwood Astro-physical Observatory, Chicago, and Results Obtained in the Study of the Sun.* He described the apparatus he had invented and perfected for photographing the faculæ and protuberances of the sun. This apparatus is the first which has successfully photographed the bright spots, showing faculæ which the eye cannot detect. Means were devised for taking on the same plate at one exposure both the faculæ and the protuberances, and Professor Hale exhibited the first complete picture of the sun ever taken. Comparison with the best plates made at the Lick Observatory showed the great superiority of the work at Chicago. An observation of unusual interest was made on July 15, 1892. A photograph of the sun showed a large spot. A few minutes later another photograph was taken, which, when developed, showed that the bright band had appeared since the last exposure. Twenty-seven minutes thereafter another photograph showed that almost the entire spot was covered with brilliant faculæ, which, by the end of an hour, had entirely disappeared, leaving the spot as at the first exposure. This indicates an eruption proceeding with indescribable and inconceivable velocity. This disturbance seems to be connected with magnetic disturbances and the brilliant aurora noted the next day.

A STANDARD DEVELOPER.

The necessity for a standard developer has been a want long felt, but one that so far has never been satisfactorily fulfilled. By this term we do not mean a developer for landscape or studio purposes, but rather for use on the scientific or technical side of photography, more especially for sensitometric and similar purposes. For such work two chief conditions are necessary, a standard light and a standard developer, and clearly the former is of little practical use if a developing solution of a uniform character is not available.

It is not our purpose here to discuss the question of a standard light beyond expressing the opinion that, though such in its strictest sense has yet to be found, there already exist several methods by which a sufficiently near approach to conformity of illumination can be secured for photographic testing purposes where the highest degree of scientific accuracy is not required. We cannot, however, claim as much for the developer, the conditions surrounding which have hitherto been so variable as to baffle all efforts to produce a solution of unvarying energy and universal applicability.

So far as the standard light is concerned we are able, as already remarked, to satisfy the requirements of photography at least to the extent of comparing the practical sensitiveness of different plates or batches of plates, though there are one or two other points upon which there may be some difference of opinion as to whether the results are trustworthy. In fact, it has been doubted whether any one light or any one developer is of any value in the comparison of plates or films in which the sensitive salts are different or which have been prepared in a different manner.

That plain bromide films differ in their relative sensitiveness to different coloured rays from those in which there is an appreciable proportion of iodide is a scientific fact beyond dispute, and therefore, in employing as the standard light one that is comparatively poor in blue and violet rays, such as gas or candle-light, a fictitious superiority will be given to plain bromide over bromo-iodide films by the sensitometer, although the latter may be fully as sensitive, or even more so, when exposed in the camera. This, however, is a fault of the light employed, and has nothing to do with the question of a standard developer.

Then, again, films differing in composition behave differently under the same developer, some developing rapidly to full printing vigour, while others require a much longer time to produce the same density

of deposit and also the same amount of detail. This has caused the question to be raised, in making sensitometer trials, whether a fixed period of development should be adopted in conjunction with the standard light and developer, or whether the latter should be allowed to act so as to "get out as much as possible" from the exposure.

It has always been our opinion—and this is strengthened by the recent researches of Messrs. Hurter & Driffield—that the latter is the proper plan, for, after all, it is the exposure, and not the development, that chiefly rules the result. If one film with a given exposure will produce a certain result in, say, five minutes' development, and no more can be got out of it by prolonging the action, while another gives precisely the same result in ten minutes, it is clearly unfair to stop the development of the second at five minutes, and dub it less sensitive than the other. It is equally sensitive, though slower to develop; and, if the conclusions arrived at by Messrs. Hurter & Driffield are correct, the gradations in both cases will be alike, provided the full time be allowed in each case. This point may therefore be put on one side, and we can proceed to consider the developing solution itself, with a view of seeing whether it can be reduced to a standard.

Briefly, the requirements in such a solution are, first of all, uniformity of composition, and strength, and also of temperature, or rather non-liability to vary in energy from slight variations in the latter respect. The first condition involves the power, not only of mixing the solution invariably of one uniform strength, but also of keeping it at that strength without deterioration; and if we take into consideration the practical impossibility of mixing small quantities fresh just when required, and the difficulty of accurately measuring minute quantities of stock solution, it will be seen that the uncertainty likely to arise from purely mechanical causes is not inconsiderable. We may now proceed to inquire how the different forms of developer are likely to answer these conditions.

Let us commence with ferrous oxalate, as differing in composition from the remaining developers of the alkaline class. This, as usually made by the mixture of solutions of ferrous oxalate and oxalate of potash, provides an apparently easy means of forming a developer of constant strength; but, upon closer inquiry, we shall find that the desired uniformity is not so readily attained. In the first place, the use of "saturated solutions" has been so frequently condemned on account of their indefinite composition, that we need not say more than that this plan is entirely out of the question, owing to the very great variations in strength that would result from changes of temperature. Even when the solutions are reduced in strength considerably below the saturation point at the normal temperature of 60° Fahr., they are far from being of a permanent composition, unless the temperature of the laboratory is kept constantly at that point. If a chance depression of several degrees occur, some of the salts will be precipitated, and, though the normal temperature may be restored, the crystals deposited will remain at the bottom of their respective bottles until heat and agitation are applied to effect their re-solution. The constant necessity for such treatment whenever a small quantity is required for use would alone suffice to deter a busy photographer from adopting this developer.

But one at least of the two solutions is far from being a permanent one. Ferrous sulphate in solution, as is well known, is subject to rapid oxidation, and, when this occurs, not only is the solution itself weakened, but a powerful retarder is formed in *ferric* sulphate, which becomes ferric oxalate in the mixed developer. Even when acidified with sulphuric acid, this change goes on, though more slowly; so here, again, the difficulty of keeping a solution of standard strength is evident. The mixed developer is spontaneously far too readily oxidised to allow of its being kept for use in that state, so that it is not difficult to recognise the thorough unsuitability of ferrous oxalate as a standard.

We come next to pyrogallol, which, as a developer for negatives, is still regarded by most photographers as the most reliable. But as a standard it presents several disadvantages. Its rapid oxidation and loss of energy in solution is the first obstacle to its use, necessitating ts preparation fresh each time it is required for an experiment, and we need only point to the irregularities likely to occur in weighing out quantities of a few grains at a time to prove the impracticability of this plan. When kept in stock solution again, not only does the difficulty of accurately measuring small quantities arise to cause uncertainty, but the sodium sulphite employed as a preservative supplies material which by oxidation introduces a gradually increasing proportion of restrainer. Thus, without enumerating any other objections, we can estimate how small are the chances of securing a standard pyro developer.

Hydroquinone possesses better keeping qualities in solution than pyro, but it suffers from the awkward failing of varying greatly in its action from very slight changes of temperature, and, owing to its comparatively low degree of solubility, its stock solution is, from the same cause, extremely liable to variations in strength from precipitation. An additional objection to this developer when employed with films of varying composition is the very different manner in which it behaves with the several haloids of silver, so that it becomes impossible to secure any reliable comparison between any but plates known to be of the same character. For these reasons, then, we are compelled to discard hydroquinone, although it forms an admirable developer for negative work generally.

Eikonogen, the next on the list, affords perhaps a better chance of supplying what we want; but here, again, the difficulties in connexion with stock solutions and its want of solubility militate against its ready adoption. While the objection caused by the oxidation of the sodium sulphite remains, the difficulty arising from the measurement of small quantities of stock solution, as well as the risk of precipitation, are avoided by diluting the solution to the actual strength for use; but then we are met by the new objection that the weaker solutions, whether of eikonogen, hydroquinone, or pyro, are deficient in keeping properties, and so placed out of court.

Para-amidophenol and its hydrochlorate, two of the newer introductions, present a better chance of success since, although so very feebly soluble in water, the solution of the strength for use keeps tolerably well for a day or two at least, and being a one-solution developer the difficulties attending the mixing of small quantities of liquid are avoided; but for a practical standard solution we require one with considerably greater keeping properties.

With regard to one-solution developers generally the same remarks apply. It is practically impossible to secure accuracy and uniformity in measuring out small quantities of the stock solutions for the development of, perhaps, a single test plate, and when diluted in quantity they lose their keeping power, and become subject to rapid oxidation.

The nearest approach to a fairly accurate standard appears to be the most recent addition to our list of developers—amidol—which, from the slight tendency to change presented when exposed to the atmosphere in dilute solution, seems to offer a way out of the difficulties mentioned in connexion with its older rivals. It is true the objection to the presence of sodium sulphite remains; but, looking at the comparatively small effect exercised on its action by restrainers, it is possible no ill, or comparatively little, may result from this cause. At least, it is worth a trial as a standard, and, if further experience with it prove that it behaves in a fairly uniform manner with the different haloids, it is not improbable that at any rate an approximation to a standard may be attained.

Not every photographer is in a position to test his plates by Hurter & Driffield's method, nor is the consumption of plates confined to those of makers who have adopted that plan of marking their rapidities. Until the practice of so marking them becomes general, the want of a standard or absolutely uniform developer will be felt.

CONVENTION JOTTINGS.—VIII.

A Run through Some of the Scotch Studios.

E. M. & R. W. Sharp (Hamilton).

In our many visits to Scotland we have observed that the photographers in the small towns there show more enterprise and pluck than are to be found in places of like population in England and Ireland, and also that there is not a place with any pretensions to a population at all in this country that does not boast of a photographer, and, as a rule, of no mean hand.

When in Glasgow we made a run out to Hamilton to inspect the premises of E. M. & R. W. Sharp, who have for many years held

sway as the photographers of Hamilton and district. Mr. R. Sharp and his sister are the active partners in the business, and it has their daily personal attention. Years ago this business was started, as such businesses usually are, by having a glass-house built behind the cottage home, and here they worked on till the place became too small for their increasing trade, and they resolved to build in the centre of the town, and the place erected is certainly an ornament to the street in which it has been placed. The whole design is of old English pattern, two stories high, and pleasingly attractive; but Mr. Sharp had considerable trouble before he could get his plans carried out. The Town Council had decided that the only form of building to be put up in the street was the severe, sandstone, plain-front edifice, and as his plans were far too ornamental and quite unsuitable they were thrown out; but Mr. Sharp was not to be beaten, so he applied again and again, till they thought better of it and gave in, and now we fancy that the obstructionists will be pleased that they have let him have his way, as the building is quite pretty and attractive.

A broad flight of steps goes straight up from the street to the first landing. The steps are composed of stone and white marble. On the landing facing you as you ascend is a draped mirror reaching from floor to ceiling, with a broad setting of flowers and plants all round the foot, which gives quite an airy, outdoor feeling to the surroundings. Around this flight of steps is a square-pillared balcony, from which the various rooms are entered.

The walls are finished in panelled wood of a light colour, varnished, with a dado of dark oak reaching up to about three feet from the floor. The showrooms and dressing-rooms are furnished with considerable taste and comfort.

The studio is fifty feet long by twenty-one feet wide, and constructed on the ridge-roof plan, being fairly well filled with glass from end to end, but it does not reach within three feet of the floor. We thought that this must interfere with the bottom lighting, but he has so much light and so much space in his studio that there is no interference whatever. He can take pictures in any part of the place, working both ends and also across the centre, having the place so well *blinded* that he can get any lighting he desires. His "boat" and other fancy pictures, where set scenes are necessary, he works across the studio, and the fittings always stand ready for use, never interfering with his ordinary work.

A balcony runs round the outside of the studio connecting the printing place, which is situated at the back of the studio.

His dark rooms are large, well aired, and fitted with all modern appliances. In the burnishing-room we saw an operation that was quite new, and which commended itself to us as a very good thing. Mr. Sharp goes in for the highest enamelling burnisher, and consequently is working Globe burnishers up to twenty-inch roller.

One thing that is insisted on by the makers of high-glaze machines is that the pictures and the mounts that they are affixed to must be damp all through if the best results are to be obtained from the machine. Now this damping process has always presented considerable difficulty, for surface dampness does not meet the requirement, and the following method is how Mr. Sharp has surmounted the difficulty. Mr. Sharp has a sink about four feet by three feet, to the bottom of which he has fixed uprights about six inches high. On these uprights he has a metal wire network nailed all over the sink; on this network he places his mounted pictures of every kind, then he runs hot water into the space below the netting, when the steam from the water renders both mount and picture perfectly moist all through in a short space of time. Another apparatus for the same purpose, which we also saw in use, was a square metal box, standing pretty high, fitted with trellis-work shelves, on which the pictures are placed; the water in the bottom being heated, and the steam passing up through the opening in the shelves, produces the desired results.

Mr. Sharp says that the damper the pictures are the better—not to be actually wet, and, on inspecting his burnished work, we felt that he knew all about it, for it was faultless.

Might this not be the reason of so many failures with these machines—for we know of many failures, especially when operators are about to use them first—this surface damping, instead of having mount and picture moist through and through? Mr. Sharp has made quite a feature of the midget picture in his place, nor does he sell them at the usual 2*s.* 6*d.* a dozen, but he touches them up and sends proofs, and supplies at 4*s.* a dozen. And he says, "Though a small thing, it has so grown upon us, that it makes quite an appreciable difference on our year's return." Group, cabinet, and *carte* work is their staple trade, and, like all successful photographers, they must stretch out, so they have had a branch establishment built at Coatbridge.

This Coatbridge branch is arranged on much the same lines as the Hamilton place, and is run by Mr. Sharp's brother-in-law. To fill up his time in the winter season he has introduced magic-lantern entertainments, which have proved a considerable source of profit, his apparatus being of first-class manufacture. His entertainments are of the best; and also, in imitation of larger towns, he has had a sheet fitted on the top of his studio between the flag-posts, where he gives nightly shows—a combination of pictures and advertisements. This seems to us to be a very good method of popularising and extending the knowledge of a place.

T. & R. Annan & Sons (Sauchiehall-street, Glasgow).

T. & R. Annan & Sons, photographers and photo-engravers to Her Majesty the Queen by special appointment, have just opened their new studios and fine art galleries at 230 to 234, Sauchiehall-street. Their previous place of business was at 153, Sauchiehall-street, but they have obtained more advantageous and commodious premises at No. 230 for their special business.

The whole premises have been planned and worked out on æsthetic lines. The entrance-way is fitted with bevelled glass cases, forming windows, with an antique filled-in door between, the arch of the entrance-way being surmounted with the royal arms, a combination that makes a very imposing front. The stairway is fitted with a pillared rail of a light construction, which is very graceful. The steps of the stairs themselves are set in with a black and white diamond pattern, which gives a lightness and effect to the surroundings. The walls are hung with a drab-coloured rough cartridge paper, quite plain, but pleasing. The showrooms and studio are worked out with the same artistic ideas, which we felt rather severe, although charmingly simple.

In the showrooms the wall paper is a neutral drab tint, and the arrangements for hanging the pictures were to us new, and the method very effective. A wooden moulding—same style as a cornice round the room—is fixed on the walls about three feet from the roof, and on a projection in this moulded pattern the brass hooks for hanging the pictures are fixed. The floor is covered with a bordered carpet in the centre, and all around the wood floor, finished in green paint, is left uncovered. The pictures on the walls are not many, but well chosen.

The studio is got up on the same lines; it is large and commodious, and capable of any amount of work. It is forty-five feet long by twenty-five feet wide; the side is fitted with rolled glass, which should give a good diffused light.

Quite irrespective of their portrait trade, which is considerable, the Messrs. Annan stand in the front rank for outdoor work of all kinds.

And in these new premises they have fitted up the plant, and are working their photogravure process, which is now so well known and so highly appreciated, as a mechanical process, whereby the most artistic renderings of pictures are produced. We visited the various rooms set aside for this manufacture, the first of these being the one in which the plates are prepared and made. We anticipated that it would have required a darker room for this work, but it does not require this. As far as light is concerned, the work goes on with great comfort. The printing-room follows next; it is fitted with the usual copper-plate presses which are used in the production of the picture. Photogravures on mounts thirty by twenty inches can be worked by the presses we saw in operation. The next was the drying-room, which is kept at a high temperature. Here the photogravure work only is finished.

At their works at Lenzie the carbon, bromide, platinum, and silver printing papers are all manufactured. Here we saw a picture of the *Fairy Raid* in carbon on an opal plate 44 × 30 inches, which for finish was as fine a thing of the kind we have ever seen.

Mr. James Annan and Mr. D. Y. Cameron, the artist, have just returned from a tour, the product of which is a very fine series of pictures that are now being prepared for exhibition in these galleries. "Notes from the Netherlands" is the intended title for the show, and it is expected to be opened in October. From the specimens of pictures that were shown us, many of which were finished in carbon, brown and red, and other examples etched, and embracing as they do most taking and popular subjects in water scenes, rustic scenes, landscapes, groups of children, &c., they are sure to make a successful exhibition, and be the means of drawing many visitors to the new premises.

ADVANCED PHOTOGRAPHIC WORK FOR AMATEURS.

IX.

In a previous article I referred to the production of combination prints from two or more negatives, and instanced how by a simple method of blocking-out such may be produced.

It frequently happens, however, that combination pictures have to be produced from two or more pictures or photographs in cases where the original negatives are not forthcoming. A very common case in point is where it is desired, say, to combine a group of six or more heads into one negative, so as to print by one operation a photograph of the entire lot nicely grouped together. In undertaking such an operation much of the ease in manipulation will depend on the nature of the various heads as they happen to present themselves. In cases where a decided similarity of style and size present themselves, the work will be greatly simplified; but it seldom happens when a number of heads have to be grouped together from photographs gathered from various sources that such are of similar sizes, or so posed as will just at once permit of their being grouped so as to make a pleasant combination as a whole. It therefore becomes necessary to fix upon a uniform size, and proceed to copy each individually. This is in itself by no means a difficult operation, the best method being to place each photograph in a printing frame carrying a sheet of glass, and pressing the back of the frame tightly up; the picture will show no grain when copied through the glass. A novice who first attempts to copy a picture having a sheet of glass in front of it, may find some trouble in getting over the difficulty of avoiding reflections from the front of the camera and other objects in front of the frame; these are reflected from the glass, which acts much as a mirror would do. Practice, however, will enable even the most trying cases to be overcome. I have often been sorely tried to avoid these troublesome reflections, but I have never yet met in with a case that did not yield to a downright hard fight to overcome them.

On my copying camera I have a large cardboard front, in dimensions about thirty-six inches by fifteen inches. In this I have an aperture cut that permits the lens just to peep through. The front of this cardboard is lined with an absolutely dull, black paper. Some thought must be exercised in getting the proper black paper; the glossy surface kind is not the proper sample. The best paper I ever saw for the purpose I got from Mr. Falconer, a jewel-case maker in Glasgow. It is absolutely matt, and can by no means throw back any reflections. It is far and away better than black velvet, and is easily attached to cardboard or any other suitable material that is used as a shield. When pictures have to be copied that do not require the camera (provided a short-focus lens is being used), being situated at any great distance from the copying frame, this cardboard shield will generally be found sufficient; but in cases where the lens is, say, three feet from the glass of the frame, then it often becomes necessary to also interpose a further preventive against the reflections from the table or copying board that is being employed to carry the camera. A sheet of good black paper laid flat on a cardboard will entirely prevent reflections being thrown upwards, and sometimes in very obstinate cases, a few sheets of black paper pasted together so as to form a curtain and hung up behind the camera will work wonders in preventing ghosts, which in nine cases out of ten are nothing but reflections. In speaking of ghosts I do not here refer to those double images caused by the use of inferior or unsuitable lenses.

The difficulty of overcoming these reflections when copying is sometimes great, but they are preventable, and no amount of labour should be spared to banish them. Their presence is easily observed by merely looking at the surface of the glass in the printing frame from a direction almost on a line with that of the lens, but when such precautions as I have mentioned are taken they will be overcome.

With a well-arranged system, therefore, of copying so as to overcome reflections, the copying of one or more photographs by daylight is a matter of great ease, for no matter what size the prints are they can easily be reproduced of a similar size.

Having, therefore, made good negatives from each, let them be varnished and retouched. Some amateurs stand aghast at the thought of retouching: it is so difficult, such fine work, so much beyond an amateur, and all that sort of thing! but, kind reader, it is nothing of the kind. Don't let anything you may have read or heard deter or frighten you from undertaking retouching. It is the professional's sheet anchor; without a retoucher he is nothing; and the sooner an amateur learns to retouch his negatives of all kinds the better for himself.

Later on I may have something to say on retouching, but meantime I wish to state that it is not a difficult operation, or one outside the capabilities of any intelligent worker.

Having, therefore, got all the negatives of a suitable size, throw off from each a print of as nearly as possible the same depth and tone.

The next step is to make a suitable mask to contain the entire lot in one group. This is also an easy operation, when the proper method is adopted for carrying it out. Still, I have known it puzzle many an old worker how to set about it.

A good sheet of writing-paper is not a very uncommon article to be found in most households, neither is a finely pointed penknife, and most, and, indeed, nearly every amateur is possessed of a set of diaphragm stops—at least, they used to be in the days before the "Iris" fad came into operation. Take, therefore, the largest stop you have, and if you have not got one yourself borrow one from some chum that has, or, better still, get an optician to turn you out of a piece of brass a circular aperture of suitable size. Lay this flat on the sheet of writing-paper, and proceed with the penknife to cut neatly out the circle inside the diaphragm, then carefully, by means of ruled lines and equal distances, lay the diaphragm down and cut out the desired number of apertures. These may assume the shape or form of diamonds, or squares, or any other desired shape. Having cut out this mask, damp it and paste it on to a sheet of clean glass, and when dry you are all ready to mount the photographs over the apertures. In this some little taste should be exercised so as to have the various heads looking in the proper directions: those to the left ought to face to the right, those to the right facing to the left.

In some cases, where it is desired that extra prominence be shown to some especial individual, a larger aperture may be made in the centre, and, of course, a corresponding allowance for the size of the head that is to occupy such a position.

Having tastefully arranged the various heads over these apertures, the entire group is then again placed in a printing frame, and the whole photographed together on one plate. The negative thus obtained is then retouched or modelled up, so as to throw off a uniform print. Such is one of the best means of combining in one picture faces that can only be gathered from varying sources.

I have referred to the advantages an amateur will derive from a knowledge of retouching. There is also another very necessary manipulation, frequently of great service in the byeways of photography. I refer to blocking out. Such enters largely into the everyday practice of all-round photography, and a proper understanding how to get about it will materially assist a keen worker.

First and foremost, a good retouching desk and a powerful pair of spectacles are a necessity. Then a good camel's-hair brush and a supply of moist Indian ink, prepared as I stated in a previous article.

There are many phases in photography in which blocking out becomes an absolute necessity, such as machinery, and other similar work; the copying of the hundred-and-one articles to be found in commerce in which it is desired to remove some objectionable background or eyesore.

In the case of machinery, we are face to face with straight lines, sometimes of long dimensions, in combination with curves and other varying shapes or outlines. The blocking out of such requires an unlimited amount of patience, and no one should sit down to attempt such work in a hurry. It is just about the most trying of all work that falls to an operator or retoucher's lot.

Some clever workers advocate the use of a pen and ruler to goround the lines, but I have never done such good work with a pen as I have with the brush. I do not say, however, that others cannot. I merely say how I have obtained the best results, and it has been as follows:—I invariable use a long-pointed camel's-hair brush of large size; one that will carry a good body of colour. With this I carefully go along the straight lines, keeping as nearly as possible to the outline. Should I, however, slightly overlap, I don't fret or worry about it: I just let the tares and the wheat grow together till the whole is done, then I set aside to dry, and, when thoroughly so, I place the negative on the desk again, and with the aid of a flat ruler and a blunt needle (a large darning-needle, set in a wooden handle) I lightly go over the parts

that are overlapped. The needle will be observed to trim up in a marvellous manner the entire work, and everything will appear true and sharp to outline. Small curves are dressed up by the needle by the hand, and all interstices, no matter how small, come in for a touch up of the needle, which invariably improves them.

I always use Indian ink on the film side, and, of course, varnish previously to applying the ink.

Pinholes, if small, are best touched out with a hard pencil, but this comes under the head of retouching. T. N. ARMSTRONG.

JOTTINGS.

I AM glad to observe that Mr. W. E. Debenham in defending the Photographic Society of Great Britain from the ungrateful attacks of Mr. H. P. Robinson, has plainly and unmistakably indicated the true cause of the latter's present hostility to the best friend (except one) he ever had. The case is in a nutshell. Mr. Robinson's long-threatened reign of privilege was terminated for ever last September, and now he is giving way to the vulgar passion of revenge. Mr. Robinson says I am hoaxing your readers in lifting the corner of the curtain which hides the details of the projected new Exhibition from the vulgar gaze, but he and I know better, unless the idea of such an Exhibition has been abandoned from lack of promised support. Another and a final question. If Mr. H. P. Robinson holds the Photographic Society of Great Britain and its exhibition in such supreme contempt as he wishes us to believe, why has he lately been to so much pain and labour in the endeavour, personally and by circular, to dissuade people from sending in pictures to the Exhibition just about to open? I (and others) pause for a reply.

I observe that one of the advantages of the new platinotype paper is stated to be that the delicate tones—presumably the half-tones—do not "fix out" much. Why should they fix out at all, since metallic platinum is insoluble in water or in the highly diluted bath of hydrochloric acid employed for clearing purposes? The loss must be imaginary and not real, as in the case of the assumed loss of density in the fixation of negatives. By the way, I find the mottling occasionally met with in the new paper can be obviated by slightly warming the oxalate solution, which also prevents the shadows acquiring a slight rustiness occasionally seen.

Is a clearing bath necessary for normal pyro-ammonia development? I think not, as under such conditions the slight yellowing which supervenes is not worth notice. The correspondent "Film Fiend," who in the JOURNAL of August 26 complains of yellowness seems to me to have a needlessly complicated system of avoiding discolouration which not improbably causes it. He first rinses the developed plate under the tap (a few minutes' soaking is much more efficacious); next alums it (which with most modern plates is not at all required), then fixes, washes, clears the yellowing in alum and hydrochloric acid, and finally rinses. The discolouration appears in the course of a few months. I think, if he would omit the first alum bath and substitute a soaking or washing for the final rinsing, the yellowing would not trouble him.

I demur to Mr. William Goode's proposition in the same number, that "perfect sunshine" is essential to success with snap-shot work. Sunshine is probably the one thing more than another which induces under-exposure in this kind of work. I think your correspondent will find that the most harmonious effects are more easily produced in a softer light than perfect sunshine is usually understood to be, with as much exposure as one can afford to give. In perfect sunshine it requires a very careful exposure to avoid hard negatives.

COSMOS.

THE ALL-ROUND HAND.

IT is a common thing at the present time to hear almost awe-struck comments upon the enormous progress of photography and photographers; and yet, granting that the progress be great, it cannot be claimed that the percentage of good work and good workers is equal to that of the times when photographers were few and their difficulties many. Considering the enormous increase in their numbers, the greater perfection of scientific instruments, the increased facilities for working, and the smoothing away of innumerable difficulties, it cannot be claimed that in the aggregate photographers have advanced proportionately with their art. The middle and lower-class ranks are filled almost to overflowing, and yearly approach more nearly to suffocation, while it is only "on the top" that room, fresh air, and a generally healthy situation can be obtained. The starting-point for success now is "on the top," for the climber, lost in the struggle of side issues, rarely reaches that point of advantage. Having surmounted the chief obstacles of science and art, he is confronted by a range of mountains called commerce, upon the highest summit of which sit a select few, basking in golden sunlight.

Without, however, inquiring minutely into the cause of the failure of the many and success only of the few, it may be said that the all-round hand, or handy man, is the natural product evolved by these circumstances. In the struggle for existence, these chameleon-like qualities of his were invaluable in tiding over a crisis in any department. He sprang up, a host in himself, to administer to a blind economy, and the way his order has grown, and continues to grow, may be taken as a sure sign of the times. "Wanted, an all-round hand," "Wanted, a man to be generally useful," "Wanted, one who can do anything and everything," "Wanted, an impossibility,"—these phrases are synonymous, and yet are still wants, attempts being still made, presumably, to supply them. It may be that photographers with wants, knowing the hopeful earnestness with which the average assistant views his own capabilities, advertise for much that they may at least ensure a little; and, generally speaking, the latter in its most meagre sense is what they secure. How, upon the face of it, can the result be otherwise? Dilettantism and dabbling never reach beyond mediocrity, though, in exceptional cases, an assistant may do many things fairly, or even well. To do a thing well and be content may be the summit of a modest ambition, but lacks the true elements of success—real earnestness to excel. Versatility was the demand by writers of a few years back, and right gallantly has their cry been answered. It is to be hoped that a louder cry for concentration will be raised when the extent of the evil becomes apparent.

"Prevention is better than cure," and therefore to aim to check the growth of an evil would be a surer means of eradicating it than by experimenting with the evil itself. The coming assistant represents the coming photographer; will an alteration in the system of his training have a beneficial result? Mr. Howard Farmer, in his paper read at the Convention, advocates this course, and suggests a remedy in the supplementary and intermediate training of scientific and technical schools. It cannot be denied that the present system of training by apprenticeship is an essential one, as much that is learnt thereby could never be taught in the schools. For instance, how else than by the old system of apprenticeship should an assistant learn the necessary tact and utilisation of circumstance in the treatment of the sitter? How else should he learn to produce work surrounded by restrictions and limitations as to time and material? Needless to say, without this knowledge, and that of many similar circumstances, he would be useless in a business. A photographer and his business are governed by circumstances, surrounded and bound down by circumstance, and no amount of scientific theory will train a man to cope with this fact; so many points are clear upon paper to the theorist that would not be recognised by him, or would have no application in the daily practical life. Given teachers whose life had been passed in a photographic business, there would still be lacking the practical demonstration upon *all* points—nay, more, there would be the impossibility of training him with, and according to, the period; for a man to go *with* the times must be *of* the times, as teacher and as student. No, the commercial training is emphatically essential, and the schools would therefore present an additional training only, the result, in effect, being a deeper and wider theoretical knowledge—or, in other words, a better-educated assistant.

It has been said quite recently that many practical assistants, excelling in particular branches of work, are too illiterate to be placed in positions of trust. This means, then, that the main choice rests between the practical boor, the educated duffer, or the mediocre all-round man, for these represent the bulk. Will the principle of technical education affect the bulk? Well, the illiterate man will become a thing of the past, certainly; but, then, the Board schools have already ensured that in part. The educated duffer may become a little less of the duffer; but surely, if a man be a duffer in spite of education, it were better to allow him be unmistakably so than to give him a false ring by technical training, and set him loose upon a profession in which brains are essential. As for the all-round man, why give him more of the quality from which he is suffering? His

knowledge is too wide already, for no detail escapes the grasp of his powerful mind. He is gorged to repletion with a photographic knowledge that would be found useful should there be any great need of *teachers* in the technical schools. His training has not been at the expense of physique, but has helped to produce a kind of gymnastic Dr. Jekyll and Mr. Hyde. One moment you see him printing in the back yard, and in the next you find him effecting a sale or securing an order for an enlargement in the reception room. Upon ascending to the studio, you disturb his genial efforts to petrify a baby into the correct photographic expression; and upon retiring to the work room he is discovered exercising his artistic skill in retouching or producing an enlargement in oils. He pervades the premises bodily, and the subtle influence of his skill and mental attainments is observable throughout the work. He carries a magician's wand that cheapens everything it touches, cheapens with the touch of mediocrity. Let him loose in a business of deservedly good name and standing, give him plenty of scope for his energy, and in a few years you shall wonder why Messrs. So-and-So have reduced their prices, and are seeking premises at a lower rental.

Will you give the all-round hand (who rank in numbers now above any other class of assistants), will you give him the advantage of a better general education? He does not need it. He recognises what it is to work well, and he tries to do it. He has ability enough, but the ability that should be devoted to one or two branches at the most is divided amongst many. From the all-round ranks come excellent managers, employers, and business men; but the position and excellence of photography depends upon the oft-sneered-at specialist. It is he who carries his work to the highest pitch of excellence, and it is to him that we look for advancement artistically, scientifically, and socially.

"Small profits and quick returns"—a maxim that never was and never will be suitable to photography—was the cry that summoned the all-round hand. An employer in a commercial crisis thought he should gain by reducing prices, and thereby securing more custom. The harm lay not so much in the reduction of prices, but in the continuation of the quality of work after the reduction. Men of the same status became frightened, and followed suit, bringing after them the natural train of events—reduced staff, reduced pay, and, in the end, poor work. A snowball does not become an avalanche without assistance. Who was to blame? The public, of course. The public demanded cheapness, and the public would take no denial. Much language has been used at the expense of a blockhead public; but, strange to say, the public have acquired an instinct quite opposed to blockheadedness, an instinct that easily determines between good and bad work. Employers, in their blindness, secured a transitory existence by cutting prices, and, when the inevitable reflection came upon them, and failure stared them in the face, rushed to their papers and periodicals, and wrote down the public. Are *you* an employer of labour? If so, you should know that the public will have the *best* you can give them at the lowest price *you will consent* to state. Good work never goes a-begging, but carries the approval of the public with it. If photographers had emulated their brethren in their work, instead of in the lowness of their prices, many would be in a better position at the present time. There is a manhole above that admits you to light, air, comfort, and success, for "there is always room on the top." The way is through excellence, which is irreconcilable with cheapness, through higher, not lower, prices, through specialism, not dilettantism and mediocrity. The upper road to greater excellence takes the public with it, merits a blessing, and is the surest way to secure it; while the opposite course generally meets with its deserts —not exactly a blessing.

The commercial question in photography seems to be too little studied. It is studied by the individual, of course, but only in the form of self-interest. One would think that, in looking backward to the greater prosperity of former years, photographers would recognise that the best way to study self-interest lies in the *trade* interest. Unity in a trade is the keynote to success, in ruling, and not in being ruled by, the buyer. To study the interest of a trade that finds one daily bread is but fair, and it to be hoped that, when photographers have recognised this, they will start an ardent crusade in favour of specialism, and lay the bogey they themselves have raised in the form of the all-round hand.

H. Colebrook.

PHOTOGRAPHY AND METEOROLOGY.

At the meeting of the British Association at Edinburgh, the Mathematical Section received the second report of the Committee, consisting of Mr. G. J. Symons (Chairman), Professor R. Meldola, Mr. J. Hopkinson, and Mr. A. W. Clayden (Secretary), appointed to consider the application of photography to the elucidation of meteorological phenomena, drawn up by the Secretary. The following are passages from the report:—

Your Committee report that the work has been continued during the past year along the lines laid down in the report for 1891.

Considerable additions have been made to the number of observers from whom assistance may be expected, in spite of the removal of several names from last year's list.

The total number of photographs received up to July 23 was 361, representing a variety of phenomena, but chiefly illustrating the results obtainable in cloud photography by various methods. This number, however, does not adequately represent the progress made, for many other photographs have been promised, and will in all probability be received in a few weeks.

The adoption by the majority of the International Meteorological Congress at Munich of the classification of clouds, proposed by Messrs. Hildebrandson and Abercromby, suggested to your Committee that it would be well to adopt it also, at least provisionally. They cordially agree with the action of the English delegates at the Congress in opposing the acceptance of a system which is entirely empirical; but, since the great majority of foreign meteorologists have determined to employ it, your Committee consider that they should adopt it provisionally. They consider it will be well to follow the example set by other countries until the further study of cloud forms, and their relation to one another, renders it possible to make a more scientific code.

Arrangements have therefore been made for the cataloguing of the collections of meteorological photographs in the possession of the Royal Meteorological Society, and of the Chairman of your Committee.

Photographs of Lightning.

Very few new photographs have been sent in as yet, but from Mr. J. H. Bateman two of great interest have been received. Following the suggestions in the instructions issued last year, two cameras were employed, the first being stationary, and the second moved rapidly from side to side. The plate exposed in the fixed camera shows four flashes, while the one which was moved shows six. A flash which is single on the fixed plate is resolved into three on the moving plate, showing that the flash did consist of a series of discharges along much the same path. The absence of reduplication in the others points to the conclusion that they were single. Two of these single flashes occupy exactly the same relative positions on the two plates, showing that they must have been simultaneous.

Your Committee regret that there should have been no opportunity of carrying out any further experiments upon the phenomena presented by lightning photographs. However, recent discoveries concerning high-tension discharges ought to elucidate the subject. Thus it seems highly probable that the hazy continuous luminosity shown by many photographs may be due to the flame of burning nitrogen.

Before leaving the subject of lightning, it may be pointed out that in Mr. Bateman's photographs the narrow-ribbon structure in each flash is no more pronounced in the moving photograph than in the one which was stationary.

The Royal Meteorological Society has received several new photographs of lightning. They all show the narrow-ribbon structure; one shows reduplication of the images of some chimneys, as well as the flash, while another shows a bright flash and several dark ones. Of this last, Mr. Robert Law, who took the negative at Melbourne, remarks that there were two flashes, the second reversing the image of the first.

Methods of Cloud Photography.

The information at the disposal of your Committee does not, as yet, seem sufficient to enable them to pronounce definitely in favour of any one method as the best. They have made some progress in ascertaining the methods adopted abroad, and also in experimental work at home. The subject divides itself naturally into two sections, dealing respectively with cumulus or heavy clouds, and cirrus or other light clouds.

Cumulus.—With all heavy clouds it is certain that admirable results may be obtained with a little practice in adjusting the stop and length of exposure. So far as the quality of the results obtainable is concerned, there does not seem to be any manifest advantage in the use of a coloured screen, of a black mirror, of specially slow, or of orthochromatic plates. Nevertheless, it is quite certain that results of a given excellence are more easily obtained on a slow plate with a strong developer considerably restrained. It is equally certain that the use of the coloured screen or of the black mirror renders the process easier still.

With correct exposure and careful development, it should not be necessary to resort to intensification of the image. If some such treatment should be required, inexperienced observers should be warned that

in the use of mercurial formulæ it is well to keep the plate in constant movement while in the mercury bath, in order to avoid undue granulation of the image.

Cirrus.—Those who have made a special study of the photography of thin clouds appear to be agreed that, in order to bring out all the details of their structure, some special device must be adopted.

By extremely nice adjustment of the exposure and subsequent intensification of the image, very fair results can be sometimes obtained; but the process is difficult and only practicable in experienced hands.

Dr. Rizgenbach, who first described the black-mirror device, recommends that exposure should be so arranged that the sky leaves practically no impression on the plate, while the thin image of the cloud must be brought out by means of Schlippe's salt (sulphantimoniate of soda).

M. Angot, in a report presented to the Meteorological Society of France, remarks that a black mirror is only advantageous when the cloud is about 90° from the sun. In theory this is of course correct, but the secretary to your Committee has found that there is a manifest practical advantage in its use for all parts of the sky, including even the immediate neighbourhood of the sun itself. M. Angot then goes on to say: The best results are obtained by coloured screens, yet the ordinary screens are insufficient. The following formula, due to M. Léon Vidal, gives every satisfaction. In a small glass trough with parallel faces there is placed a solution made with the proportions—

Sulphate of copper	175 grammes.
Bichromate of potash	17 ,,
Sulphuric acid	2 c.c.

These are dissolved in 100 to 500 cubic centimetres of water, according to the thickness of the trough and the results to be obtained. The sulphate of copper arrests the red rays, and the bichromate the blue and violet. The plates used were Lumière's orthochromatic, and the exposure from ·5 to ·8 second.

Your Committee regret that they have not yet received any illustrations of the results obtainable by the above means, but it is hoped that an exhaustive trial of the method may be carried out in the course of the coming year.

The Secretary to your Committee has continued the comparative trial of slow and ordinary plates with or without a black mirror. He reports that ordinary plates and direct exposure may often give satisfactory results when the background of sky is a clear deep blue. If, however, it is at all hazy, the correct exposure becomes extremely difficult. With slow plates, however, such as Mawson & Swan's transparency plates or photo-mechanical plates, it is fairly easy to obtain results of high excellence.

With the black mirror ordinary plates give excellent results; but here again, unless the clouds are moving with unusual rapidity, or unless the light is very bad, there is a great advantage in the use of slow plates. It is, indeed, easy to obtain a fairly dense image of any cloud, however luminous and however thin, by the combined use of mirror and slow plate. Such means give abundant detail and full gradation of light and shade, even when the sun is actually in the field of view. Exposure would vary from about ·2 to about ·8 second with an aperture *f*·11.

The developer used in all these experiments is the familiar formula with pyrogallol and sulphite of soda considerably restrained.

Special attention should be drawn to the admirable series of cloud studies presented to the Committee, which were taken by Signor Mannucci at the Vatican Observatory under the direction of Padre Denza, S.J. These show what can be done by direct exposure, Signor Mannucci recommending a slow plate for the more difficult subjects. The pictures taken by the Secretary to your Committee in a similar manner show the value of the slow plate and black mirrors.

Miscellaneous Photographs.

With regard to miscellaneous photographs of meteorological interest, your Committee regard with some satisfaction the number of pictures they have been able to secure which show the violence and severity with which the great blizzard of March, 1891, visited the south-west of England. They believe it is of great importance that fairly complete pictorial records should be kept of all such abnormal events.

They are also pleased to be able to report that several of the photographic periodicals have recently manifested considerable interest in the work, one paper having just offered a series of prizes for the best meteorological studies, the editor having offered to present any competing pictures to your Committee. Several photographic societies are also taking the matter up, and your Committee hope that the effect of such powerful aid may rapidly make itself felt, both by increasing their collection and by adding to the number of contributors.

In order to show the widespread interest already taken in the subject, the catalogues of the three principal collections are appended.

In conclusion, your Committee ask to be reappointed with a grant of 15*l.*, in order to follow up properly what they regard as a satisfactory start.

THE FIRST APPLICATION OF BROMINE.

The successful demonstration of Daguerre's process by Joseph Saxton, says Mr. Julius F. Sachse in the *American Journal of Photography*, together with the subsequent experiments by Robert Cornelius, has excited a widespread interest in the scientific circles of Philadelphia. Among the scientists who thus became interested in the new process was Dr. Paul Beck Goddard, assistant to the professor of chemistry in the University of Pennsylvania, who then resided or had an office on the east side of Ninth-street, opposite the University.

Dr. Goddard at once opened communication with Mr. Cornelius, examining the apparatus, and investigating carefully the manipulations as practised thus far by the latter. These visits ended by a duplicate apparatus being made for the use of Dr. Goddard, who entered into a series of chemical experiments, in which it is stated that he had the assistance of the celebrated chemist, Professor Robert Hare.

It will be noted that thus far all the results shown by Saxton and Cornelius had been obtained by the use of dry iodine as a coating for the plates.

In the previous chapter it has been stated that the first two portraits ever made by the daguerreotype process were made by Cornelius—the first of himself, the other of his children, which is also still in existence. The honour of making the third portrait belongs to Dr. Goddard. This was also made in the open air in the rear of his residence on Ninth-street, by the use of dry iodine. The subject or sitter was a student in the medical department of the University—Aaron D. Chaloner. An interesting account of this sitting was given the writer by an old physician still living, who was present on this occasion, fifty-three years ago, while a student at the University of Pennsylvania.

The subject, Chaloner, was seated upon a chair in the bright sunlight, with the injunction not to move, but he became restless before even the preliminary operations, such as focussing, were completed. Dr. Goddard, fearing that the attempt might result in failure, obtained from Dr. Hare's laboratory in the University opposite a blue reflector of some kind, and after the focussing was completed, a blue reflection was thrown upon Chaloner by an assistant, in such a manner as to neutralise the direct rays of the sun. The exposure, it is stated, was prolonged to about three minutes, and resulted in a fair picture.

The First Instantaneous Pictures.

The investigations and chemical experiments of Dr. Goddard were mainly confined to chlorine, bromine, and iodine, and he was not long in discovering that bromine, combined with iodine on the plate, would reduce the time of exposure from one-third to one-half within doors* while in his yard, in the open air, the impression was almost instantaneous. These experiments resulted in the production of a perfect specimen by the use of bromine in December, 1839, which was subsequently shown at the American Philosophical Society (*Proc.*, vol. iii., p. 180).

This is the first record of the employment of bromine in the photographic process. It was during this series of experiments with bromine that Dr. Goddard succeeded in obtaining several good views and portraits instantaneously in the open air, which were the *first instantaneous pictures made by any heliographic process in the world.*

The application and use of bromine as an accelerator was kept a close secret by Goddard and Cornelius for about two years. It was this use of bromine, together with Cornelius's superior skill in polishing his plates, which account for the great beauty of his early daguerreotype miniatures. There is still in existence a plate,† unfortunately in a very dilapidated condition, which it is claimed was one of Goddard's earliest bromide efforts. It represents two male figures in a *négligé* attitude, one leaning back in a chair, the other against a fence. The picture was, without a doubt, made in the open air.

It has been stated to the writer by several old persons who knew Dr. Goddard well at that time, that for a short time he also made for pay Daguerreotype miniatures at his residence in Ninth-street. His appointment as demonstrator of anatomy in the University of Pennsylvania, in the year 1841, diverted his attention from professional portraiture. He, however, did not relax his interest in the new art.

* The laboratory of Dr. Goddard was lighted by a skylight.
† Now in possession of the writer.

In the latter part of the year 1841, a young man, an assistant to Cornelius, was approached and tampered with by parties from New York, who had opened a Daguerreotype gallery there. This individual succumbed to the temptation of the offers made to him, and secretly left Cornelius and worked for two weeks in New York, divulging the whole secret of the use of bromine as an accelerator. As soon as this fact became known, Dr. Goddard at once published the discovery, and the process became public property, and soon came into general use. At a subsequent stated meeting of the American Philosophical Society, held January 21, 1842, Dr. Goddard presented specimens of photographic portraits made by the diffused light of a room, and by the peculiar process in which bibromide of iodine is used. This process he described, and stated that he had ascertained, only on that day, that a similar method had been presented to the French Academy, which, however, in some particulars, was inferior to his own. (*Proc. Philo. Soc.*, vol. ii. p. 144). On the 4th of March following, Dr. Goddard exhibited, before the same society, specimens of daguerreotypes on a surface of gilded silver, and stated that the surface of iodide of gold was more susceptible to the Daguerreotype action of light than that of the iodide of silver, that the surface of the plate might be polished without injury before the action of the iodine, and that the lights came out better than on the silver surface (*Proc. A. P. S.*, vol. ii. p. 150).

In English and Continental text-books upon photography, the claim for priority in the use of bromine as an accelerating agent is usually accorded to one John Goddard, a London optician. That this is clearly an error is apparent from the above indisputable record. The honour for the first use of bromine as a sure and valuable accelerator and the subsequent application to Daguerreotype and photography, without a shadow of doubt belongs to Dr. Paul Beck Goddard, of Philadelphia.

Paul Beck Goddard, a native of Philadelphia, was born in the year 1809, gradnated in the medical department of the University of Pennsylvania in 1832, appointed Demonstrator of Anatomy for the same institution in 1841, a position which he resigned in 1847, when called to the chair of Anatomy of Franklin Medical College, which he filled until 1852. In 1847 he was appointed Surgeon to the First City Troop—Philadelphia's crack military organization. From 1859 to '63, Dr. Goddard was connected with the Philadelphia Board of Health, from 1863 to 1865 he served as surgeon in the U. S. Volunteer Service. He died July 5, 1866.

It is further a noteworthy fact that, while Philadelphia scientists laboured to shorten the time of exposure by chemical means, confining themselves exclusively to the Daguerrean apparatus, which time has proven to be the only practical method, experimenters in New York attempted to achieve the same object by the use of mechanical inventions and such chimerical apparatus as a reflecting camera, and other equally impracticable devices, which were all abandoned as soon as Goddard's Philadelphia process had been surreptitiously obtained.

The First Snap-shot.

Among early experimenters in heliography whose names should not be forgotten, is that of Dr. Joseph E. Parker, who lived No. 61, North 7th-street, then a fashionable quarter of the city. Dr. Parker was a dentist by profession, an active member of the Franklin Institute, and one of the first experimenters to use the Daguerre process for outdoor views, street scenes, &c. He was also one of the pioneers in micro-photography. It is more than probable that Dr. Parker was let into the secret of the use of bromine at an early day, as it would have been impossible to obtain the instantaneous views by the use of dry iodine.

A heliograph (daguerreotype) upon a silvered plate 6 × 5 inches, made by Dr. Parker in the month of March, 1840, is now in possession of the Historical Society of Pennsylvania. It represents Race-street Wharf at the Delaware, and, after the lapse of more than half a century, is still (except where mechanically injured) in a perfect condition, and in definition equal to many of the amateur efforts of the present day.

A series of these views by Dr. Parker were exhibited in the "Departments of Fine Arts" at the Franklin Institution Exhibition held during October 1840. These specimens naturally attracted much attention, and were greatly admired for their beauty and fidelity to nature. The only question which arose to their detriment was the as yet unknown factor of permanency. The committee on premiums awarded Dr. Parker a *certificate* of *honourable mention* for his exhibit.

How long Dr. Parker remained a disciple of the daguerrean art the writer has been unable to determine, nor does there seem to be any record of any specimens from him at any subsequent exhibitions.

DOES VERSATILITY PAY?

From the tone of the discussion which has followed Mr. Howard Farmer's paper read at the Convention, it is plain to see that photographers are not quite satisfied with the present acquirements of their assistants; in short, there is a demand we are told for "all-round men." On the whole, the demand is a reasonable one. The editor has been called to account for suggesting that many branches of photography are to be learned in a comparatively short space of time; but the editor was well within the mark, for, given a young man of average intelligence, he should be able in two years or less to operate, retouch a little, print in various methods, enlarge, and copy. Much more than this is to be learned of photography in two years by older persons; but for the youth enough is as good as a feast, and "sufficient unto the day is the photography thereof."

Salaries do not run very high in the trade nowadays, and why? On account of the numbers engaged in and conversant with photography—the ease with which certain primary knowledge is attained. A retoucher who, five years ago, would ask and receive a salary of 3*l.* weekly could now be had for two-thirds of that sum, and would not expect to be called on to do more than retouch, and operate occasionally. This is where an error has crept in; specialism has been too rampant. On the other hand, men may be none the better off for knowing the Alpha and Omega of photography. As an instance, I mention the case of a gentleman I am acquainted with—a chemist, qualified, and receiving pay from 150*l.* to 180*l.* yearly. He took up, as the expression is, as a hobby, the fascinating art. He became, in two years, an expert photographer—wet-plate and dry, all the known printing processes, enlarging, photo-mechanical and micrographic work. The certificates of the City and Guilds Institute were evidence to his theoretical knowledge, and a frame of medals bore testimony to a general excellence of manipulation. As is often the way in such cases, my friend was the recipient of much advice; all his *drug* friends advised him to go in for photography entirely, and all his *photographic* friends recommended him to stay where he was. However, receiving an offer from a good firm, from pure love of the art the plunge was made; but it proved to be an error—it was the other extreme. My friend was the all-round man; he could operate anywhere and everywhere, retouch, print, enlarge, copy, make slides, instruct the pupils, keep the books, and look after the residues. He was "at home" in all departments. As might have been expected, he got much "kudos," but little coin—never quite so much as the gentleman styled "the head retoucher," and who could (and would not if he could) do little else. This seemed hardly fair, and my versatile friend drifted once more, and now earns more than ever before at an entirely different profession, studied in spare moments. Talking over this and other matters, he said, and I thought it of importance, that he always missed something, difficult to define, in his photographic education, but which was apparent in others who had served their time (an apprenticeship, in fact) to the profession. Photographers cannot, I am sorry to say, be accused of excessive liberality (and perhaps it is not altogether their own fault) in the matter of salaries, which may account for much. These salaries, to my mind, want, like those in the Church, more equalising; the printer, the man who probably is very often the all-round man of the studio, must not be allowed to starve at the expense of the retoucher. There is a medium between the specialist and the versatile individual who is always a student, and sometimes a professor—the man, in fact, who knows too much for the nineteenth-century studio. The one will get, *pro rata*, well paid, the other never value for his services.

J. Pike.

Our Editorial Table.

The *Idler* for September displays a continued advance in respect of its pictorial contributions upon former numbers. The article on "Boxing with Four Fists," by Mr. Robert Barr, which is partly illustrated from photographs, is a clever exposition of the French system of boxing. The other contents of the magazine are excellent, the pictures being notably well reproduced.

Fitch's Films.

Some recent experiences with these films have very favourably impressed us with their good qualities. Photography with cut films is rendered most agreeable by means of Mr. Fitch's productions. The celluloid supports possess remarkable flatness and purity, and are thus

admirably adapted for the purpose, and the quality of the sensitive coating is uniformly excellent. In the preparation of Fitch's films, great technical skill is evidently displayed.

Richard's Patent Corners.

These are small, gummed, triangular pieces of paper for attaching photographs to mounts, albums, and scrap-books. They should prove useful either temporarily or permanently.

The "Cadett" Plates.

Cadett & Neall, Ashtead, Surrey.

Mr. Jas. Cadett's long experience in the nice art of dry-plate making is a guarantee that any sensitive product emanating from the house of Cadett & Neall is sure to reach the highest level of excellence. We have just submitted a sample of the firm's "Lightning" plates to a practical test, with the most favourable results. Their speed, according to Messrs. Hurter & Driffield's system of measuring the rapidity of plates, is 59°, which, translated into actual results, proved to be a degree of rapidity not excelled by any other plate with which we are acquainted. This high sensitiveness is accompanied by an ease and rapidity of development with a normal solution not always associated with very rapid plates, especially taking into account the fact that the "Lightning" plates yield density with the utmost readiness. Regarded from the point of view of technical properties, the "Lightning" plates are irreproachable.

"The Photographer:" a Monthly Record of Photographic Progress.

Elliott & Son, Barnet.

This is a small four-page pamphlet giving, *inter alia*, interesting reading matter on current photographic topics. It is unfortunate that when Messrs. Elliott issued it they were seemingly unaware that a monthly publication bearing the same title (published by Messrs. G. Mason & Co.), and a copy of which is before us, had already been in existence for several years.

Studies in Photography.

By John Andrews, B.A. London: Hazell, Watson, & Viney, Limited.

In these *Studies* Mr. Andrews devotes a few chapters to the consideration of the claims of photography to rank as an original art. Naturalistic photography he considers an attempt to reproduce the mystery and beauty of nature under poetical aspects, and in accordance with the rules observed by the masters of the art. "A glance at the walls of the photographic exhibitions shows that art ideas and motives are stirring the photographic world; and though no reasonable person imagines that photography will ever equal or supersede brush work, still there is a field, and a wide one, it may profitably occupy." The author in a chapter on "The Artistic Use of a Hand Camera" considers that a hand camera should be used strictly as a hand camera, if the best results are to be obtained. But we know many who do not, except on occasion, use hand cameras except as those of the ordinary kind mounted upon a stand, and claim that in this way only can the *best* results be obtained. There are chapters on the Study of Nature, the Study of Art, on Portraits and on Atmosphere. The book (202 pages) will prove good suggestive reading. It is in the main a collection of articles contributed to the *Photographic Quarterly* and other reviews. It is well printed and contains several illustrations. Price, 3s.

Burton's Photographic Printing.

London: Marion & Co.

This is a second edition, revised and enlarged, of Professor W. K. Burton's *Practical Guide to Photographic and Photo-mechanical Printing Processes*. Some matter which appeared in the first edition has been excised, and new matter introduced instead. The history, theory, and practice of most, if not all, printing processes in actual use are fully dealt with, the information as regards photo-mechanical printing being especially complete and practical. The book, which contains 414 pp. and is well printed, is possibly the most comprehensive guide to all branches of photographic printing extant.

Fallowfield's *Photographic Remembrancer* for August-September summarises and particularises the latest novelties down to the most recent date. Mr. Fallowfield is unexcelled in enterprise.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 15,901.—"An Improved Process for the Transfer of Photographic Images." W. H. Slader and L. Siedle.—*Dated September* 5, 1892.

No. 15,956.—"New or Improved Process and Apparatus for the Tentative Exposure and Development of Pictures obtained by Photography." E. H. Hardy.—*Dated September* 6, 1892.

No. 15,971.—"An Improved Combined Carrier and Dissolver for the Optical Lantern." S. J. Levi & Co.—*Dated September* 6, 1892.

No. 16,012.—"Improvements in and in connexion with Optical Lantern Slides." W. C. Hughes.—*Dated September* 7, 1892.

No. 16,026.—"Improvements in or connected with Jet Apparatus for Lime and other Lights." A. Kershaw.—*Dated September* 7, 1892.

No. 16,074.—"Improvements in Racks Used for Soaking or Drying Photographic Plates." J. Pumphrey.—*Dated September* 8, 1892.

No. 16,196.—"Improvements in Mounts for Photographs and the like, applicable also for Albums." F. M. Bridgwater.—*Dated September* 10, 1892.

No. 16,264.—"An Improvement in the Manufacture of Photograph Albums." Complete Specification. G. Albert.—*Dated September* 10, 1892.

PATENTS COMPLETED.

Improved Apparatus for Printing Lantern Slides from a Photographic or like Negative.

No. 17,098. James Dore, 27, High-street, Sandown, Isle of Wight. *August* 13, 1892.

A frame of wood or other suitable material containing a panel with opening in the centre rather smaller than the transparency plate to be used. In use a negative (photographic or other) is placed at the back of panel, and is kept in position by a diaphragm of wood or other suitable material hinged to the inside of frame and fastened by a spring catch, allowing any part of the negative to be adjusted to the opening in panel. In this diaphragm is an opening exactly opposite that of the panel to receive the sensitised plate. A back or cover of wood or other material, also hinged to and inside frame, fits over the diaphragm, and fastens by turn-buttons of brass or other material. On the inside centre of back is fastened a flexible pad, which keeps the sensitised plate in contact with the negative when the cover is closed.

There are no loose parts, and any number of duplicates can be made from the same negative without readjustment.

Improvements in Camera Obscuras.

No. 19,597. John Richard Fielding, Roach House, 2, Grosvenor-road, Douglas, Isle of Man.—*August* 13, 1892.

Hitherto it has been customary to have only one reflector, lens, and table, on to which table the picture is shown in camera obscuras, but I propose to have a series of reflectors, lenses, and tables round the room (I prefer about twelve of each, but more or less may be used). By this means the view of the country all round the camera obscura can be shown on the tables at one and the same time. These tables I propose to use on an incline to give a sharpness in the picture for long and short focus, but may be horizontal if required, and each reflector, lens, and table is divided from the others by screens or partitions if required.

The claims are:—1. Having a series of reflectors and lenses which will reflect pictures on a table or tables in the camera obscura. 2. Dividing the pictures on the table or tables from each other by screens or partitions.

Improvements in and connected with Photographic Apparatus for Surveying and Field Sketching Purposes.

No. 14,231. Herbert Weld-Blundell, Wellington Club, Grosvenor-place, London.—*August* 20, 1892.

This invention has for its object to adapt a photographic camera to fulfil the requirements of surveying and field-sketching operations for military and other purposes, and it relates principally to the combination with a hand or other portable camera of means or appliances whereby a record may be easily obtained of the true relative bearings of the station and sighting points, that is to say, of the place at which the camera is situated when a photograph is taken and of any distant object forming a prominent feature in the picture.

For this purpose, the screen upon which the picture is focussed or viewed, is divided and graduated in the manner of a protractor, either by lines upon the glass, or by a skeleton or wire protractor so applied as to be visible upon or through the screen. Upon, or beneath, or otherwise in proximity to the focussing screen a magnetic compass having a transparent card is mounted above the optical axis of the camera, whereby orientation of the picture reflected on the screen, and, consequently, of the landscape or image photographed, is obtained.

Within the camera a fine index wire is mounted perpendicular to the base of the picture, and parallel to the sensitive plate, another wire moving with the first being so arranged with regard to the view-finder or focussing screen as to cause its shadow to be projected thereon, so that, upon this index being made to coincide with the position with regard to the vertical centre line of the picture of the image of any sighting object therein, there will be produced upon the resulting negative a fine vertical line corresponding to the image of the sighting object to serve as a datum line from which to construct the resulting chart.

Within the camera another index, parallel and close to the plane of the negative, so as to cause its shadow to be projected thereon, is so mounted as to be adjustable to any angle through an entire circle, and is operated by gearing connected with an external index, which is set by reference to the magnetic

compass, and works over a correspondingly graduated disc in order to produce upon the negative a graphic record of the orientation or bearing of the camera when the photograph was taken.

Upon the side of the hood of the focussing or view-finder screen a clinometer may be mounted to enable the elevation or depression of the camera at the moment when the photograph was taken to be ascertained. This instrument may be detachable, and marked with *radii, formulæ*, measurements, and other indications used in working out calculations.

For accurate observations with a prismatic compass provision may be made for mounting this instrument upon the camera directly above the optical axis thereof.

Improvements in Apparatus for Producing Enlarged Copies of Photographs.

No. 15,282. Edgar Clifton, 108, Regent-street, London, Middlesex. *August* 20, 1892.

An improved photographic enlarging apparatus, consisting of a baseboard of sufficient length, which may be of wood, metal, or other suitable material, and divided into two or more sections, attached to each other by means of hinges, pivots, or other suitable contrivance, so as to permit of its being easily folded. Upon the centre division I erect a stage or frame, for the purpose of carrying the condensing lenses as generally used; in this frame, in front of the condensing lens, is an aperture or recese to carry the negative to be enlarged, which may be placed in without any other fitting, or, preferably, in the special frame or carrier hereinafter described. In front of this, again, I attach a camera body of the ordinary form, and of suitable dimensions; this may be constructed either of wooden boxes sliding in each other, or may be made of wooden frames at each end, attached to each other by means of a folding bellows of leather, indiarubber, cloth, paper, or other suitable material, the front portion of this camera body being made to slide out upon the front section of the baseboard when in use. Focussing may be effected by a rack and pinion, screw, lever, slide, or any method in common use by photographers. To the back part of the frame, carrying the condenser, I attach a sliding body, which may be made of metal, asbestos, millboard, or other suitable material, so arranged as to allow the posterior portion to be approached to, or withdrawn from, the back surface of the condensing lens by sliding upon the rear section of the baseboard without permitting the egress or admission of light, except through an aperture in the end. For greater security I prefer to furnish the front portion with au inner lining, between which and the outer cover the back portion is allowed to slide.

To the aperture at the back of the sliding box I attach a lamp, gas burner, or other suitable source of light, such lamp being protected and covered by a metal chimney or sheath, so that no light can escape except in one place, which is placed opposite the aperture in the back of the lautern body while the apparatus is in use. When not in use the lamp and its chimney or sheath are to packed inside the sliding body of the lantern, which is made of such form and dimensions as will permit of containing it when closed, such body being fitted with suitable springs or fastenings so as to hold the lamp and its sheath, chimney, or cover firmly in position, thereby preventing injury when travelling. Another part of my invention relates to an improved frame or carrier for holding photographic plates in the aforesaid or other photographic enlarging apparatus.

I make two frames of wood, metal, *papier mâché*, or other suitable material, having an opening in each of the size of the plate or portion of plate from which it is desired to enlarge. These two frames are hinged together along one edge, and are provided with a suitable clasp or fastening, so that they shut and clasp in the same way as a book. The inner surface of one of the frames may, if desired, be faced with cloth, and the inner surface of the other is fitted with a number of cushions, pads, or suckers of indiarubber, leather, or other elastic material, arranged round the opening so that the photographic plate may be held firmly in any position when laid thereon, and the frames closed and clamped. Or I may substitute a continuous strip of rubber or leather, placed round the aperture in the carrier in the place of the separate pads or suckers aforesaid. The carrier or frame is preferably made larger than the plate for which it is designed, to allow of adjustment in a lateral or vertical direction.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
September 19 ...	Dundee Amateur	Asso. Stndio, Nethergate, Dundee.
„ 19 ...	Hastings and St. Leonards	
„ 19 ...	Leeds (Technical)	Mechanics' Institute, Leeds.
„ 19 ...	South London	Hanover Hall, Hanover-park, S.E.
„ 20 ...	North London	Wellington Hall, Islington, N.
„ 20 ...	Oxford Photo. Society	Society's Rooms, 136, High-street.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

September 8.—Mr. A. Haddon in the chair.

The Chairman presented a copy of the *Argentic Gelatino-Bromide Workers' Guide*, by J. Burgess, published by Morgan & Kidd, about the year 1880, and drew attention to the fact that it contained the germ of the "Developan" which was recently introduced.

Mr. C. G. Norton exhibited his non-photographic lens tester for testing the flatness of field of a lantern objective. This consists of a piece of muslin mounted between plain glasses. For use, the tester is placed in the lantern stage and focussed on the screen, when the centre and sides of the image may be compared for flatness. He also showed his registering templates, for securing exact coincidence of discs when using a biunial or triple lantern, which can also be used to ascertain whether two or more lenses are of the same focus, and to test whether a lens is rectilinear. They are made by a mechanical process which ensures two or more being absolutely identical, the glass being fixed in its place previous to the lines being drawn upon it. He also showed an adjustable runner for lantern stages, to raise or lower the slide at one or both ends to the extent of three-sixteenths of an inch, which is ample for the purpose.

Mr. E. W. Parfitt exhibited Messrs. Newman & Guardia's new shutter, made in aluminium, which admitted of pneumatic regulation of the exposure from the fiftieth of a second down to one second; and also the same firm's changing back, applicable to an ordinary camera, which permitted of any particular plate from a number being used.

Mr. B. Foulkes Winks, in reference to the new developer, amidol, exhibited a negative developed therewith, and said he found a difficulty in getting density, although prolonging development for ten minutes, and using five drops of a ten per cent. solution of bromide of potassium.

Mr. T. E. Freshwater observed that he had recently set his little boy to develop two or three plates with amidol, and the negatives turned out nice and dense.

"The Stop in a Single Lens."

The following question from the box was read: "How is the proper position of the stop in a single lens ascertained?"

Mr. W. E. Debenham said it was impossible to say if there was a proper position. When Grubb issued his single lens many years ago, he arranged for an adjustable stop, so that as the stop was nearer the lens it would cover a wider field, while further off the field would be flatter. It was wrong if the stop was in such a position so that one got flare. Generally speaking, the further from the lens the flatter the field. In architectural work, the further the stop was from the lens, the more one got the particular distortion which belonged to single lenses. It was better to use a very small stop near the lens.

The Chairman said it was recommended in certain books to fix the stop at a distance of one-fifth of the focal length of the lens.

"Development when Travelling."

Another question was: "What is the best method of treating developed plates when travelling, so that fixing may be postponed until after the return home?"

The Chairman thought it best to wash and dry the plate. If it were then exposed to light, it would be very little injured. He did not think light would affect its printing qualities.

Mr. Debenham doubted whether the plates could be washed enough to prevent light affecting them. Some plates showed red in the shadows on being exposed to light, while others remained unaffected.

Mr. A. Cowan would always prefer to fix where possible.

Mr. W. H. Harrison observed that Mr. England's plan was to wash a little of the hypo out, and to well wash the plate when he came home.

Mr. Debenham said that this might do for photographers who were well up in it, but for those who were not the negative might be ruined by turning yellow.

Mr. Foulkes Winks found that on washing negatives which had already been dried and washed, there was a tendency of the film to flow off the glass.

"Is there any Adequate Theory of Reversal?"

Mr. T. Bolas said that in the collodion days there was a notion that the red rays retarded the action of light on the plate, one wet-plate operator saying that there was so much red light in his room that it neutralised any white light which gained admission. He suggested that the experiment as to whether red light prevented white light acting on a sensitive surface might be tried with a biunial lantern at a future meeting.

Mr. J. S. Teape detailed his experiments as given at previous meetings, proving by a series of gradnated exposnres that no re-reversal took place.

Mr. Debenham said that in his experiments he could not change the point of reversal by any variation of the developer. He found that the time necessary to reverse was about 4,000,000 times necessary to produce the merest trace of a developable image.

The Chairman, in reference to the time of development of reversed images, suggested that possibly the liberation of bromine tanned the film in parts, and that if the developer were given long enough to act on those parts it might produce an image. Mr. Wellington had tried to get reversal on a collodio-bromide plate and could not. By passing a solution of chlorine gas through a solution of gelatine, the latter was made insoluble in water, and something of the sort was most probably the case with bromine.

Mr. Harrison said it was a curious thing that negatives might be produced by reversal on some plates and not on others. A photo-mechanical printer in the south of London always used this method for obtaining reversed negatives.

After further discussion on this subject the meeting adjourned.

North London Photographic Society.—September 6, 1892, Rev. E. Healy in the chair.—This meeting, the first after the summer vacation, was devoted to reports of holiday work, and a good number of specimens of hand-camera work, as well as of larger sizes, occupied the attention of the members. It was noticeable that a considerable proportion had been taken on isochromatic plates, the results fairly showing the advantages of the colour correction.

Almost without exception the prints were on Ilford or Eastman printing-out paper, toned under various conditions of bath, but in all cases with satisfactory results. Messrs. Beck's Bynoe printing frame was shown, and attracted a good deal of interest, and the new developer, amidol, was mentioned as to be reported on very shortly. Next meeting September 20, when a practical demonstration of retouching will be given by Mr. Redmond Barrett.

North Middlesex Photographic Society.—September 12, Mr. H. Smith in the chair.—Thirty-five members and a number of visitors were present. Mr. Beadle addressed the Society on *Lantern-slide Making*. He showed a frame for the purpose of printing by contact from any part of a half-plate negative, made from a whole-plate printing frame. The ordinary back was removed, and two thin boards substituted; the inner sides were covered with a soft material, and a square hole, 3½×3½, cut in the centre of each. The negative was sandwiched between them, leaving the selected part visible through the opening, the whole arrangement being clamped together with the pressure springs. The lantern plate was dropped into the opening over the negative, and secured in place by a lid, fastened with one pressure spring. Mr. Beadle referred to the various lantern plates on the market, their peculiarities, and the tones to be obtained on them. He had long wished for a print-out plate, and had tried, with success, the following formula, which he had recently seen:—No. 1, Silver nitrate, ½ ounce; citric acid, 60 grains; water, 1 ounce. No. 2, Nelson's No. 1 gelatine, ½ ounce; water, 6 ounces. No. 3, Alum, 20 grains; Rochelle salts, 20 grains; ammonium chloride, 10 grains; water, one ounce. No. 2 was gently warmed, and No. 3 added; No. 1 was then added, drop by drop, with constant stirring, heated to 150 degrees, and filtered through two thicknesses of muslin, and the plates coated by pouring a pool in the centre, and flowing all over. The only trouble he had met with was that it remained slightly tacky, and would stain unvarnished negatives. Lantern slides, large transparencies, and opal plates, produced by this method, were passed round for examination. The colours obtained by toning with the borax and cyanide baths were very fine, and, though the plates had been repeatedly removed during printing for examination, no signs of doubled images were visible, as in replacing the plate care was taken to bring it into close contact with the same side and end of the printing frame. The lecturer then dealt with the minutiæ of exposure, development, and toning of slides made by gaslight, and ended by making one or two slides of great beauty. A hearty vote of thanks was accorded to Mr. Beadle for the seasonable lecture he had given. The competition of views taken at Welwyn and Hadley was held, Mr. Allpress being declared the winner. The next meeting will be held on Monday, September 26, Mr. Mummery in the chair, when Mr. E. J. Wall will lecture on the *Life of a Dry Plate*. Visitors welcome.

Hackney Photographic Society.—September 6, Mr. A. Barker in the chair.—Several members complained of the inaccurate manner in which meetings had been reported during the absence of the hon. secretary, and in consequence the minutes of the preceding meeting were ordered to be rewritten. Mr. S. J. Beckett, of 6, The Grove, Hackney, was nominated for membership, proposed by Mr. Sodeau, and seconded by Mr. Hensler. Donations:—A cabinet portrait of Mr. Harverson, taken by himself for the album, and six blue glasses for testing dark-room lights, from Mr. Sodeau. Work was shown by Messrs. S. Beckett, Harverson, Hudson, Nunn, and Sodeau. Mr. Nunn showed the result of testing a ruby lamp with an Ilford red-label plate; it was pronounced safe. Mr. Hudson showed a negative and lantern slide developed with amidol. He was much pleased with this new developer, and had developed eight plates in succession with one portion of developer. Mr. Beckett did not think that amidol would be very suitable in cases of over-exposure, but thought that it would prove excellent in cases of under-exposure, and for lantern slides, &c. Mr. Hudson had found that some sulphite of soda, which had been exposed to air, did not completely dissolve in water, and did not prevent stain to the same degree as the fresh substance. Mr. Sodeau said that this was due to its having been oxidised to sulphate. Mr. Gosling asked whether sulphite of soda and meta-bisulphate of potash would keep in solution. It was stated that they would keep if air be excluded; solutions of sulphite of soda should be acidified. A member had developed a lantern plate with pyro and sulphite of soda only; it was remarked that sulphite of soda is alkaline. A member asked whether pyro-soda could be used for developing more than once. Several members did so, but others thought that it was not advisable, especially in cases of under-exposure. Mr. Capell asked what effect citrate of soda had in developing. It was stated that it was very useful in cases of over-exposure, as it allowed the negative to gain in density, while preventing detail from coming out.

Richmond Camera Club.—September 9, the President in the chair.—Referring to the soda developer mentioned in the minutes, the Chairman remarked that, for some kinds of plates, the amount of soda should be halved. For time exposures it was advisable to begin with even less than that amount. Mr. Faulkner inquired which was the best method, to obtain density first and detail after, as he had seen lately recommended, or *vice versâ*. He preferred getting the detail first of all; with rodinal, he had been unable to obtain vigorous negatives. Mr. Ramsay had had no trouble on that score. Mr. Ennis could get better density with pyro-soda than with rodinal. Mr. Davis wished to know why, in a recent article, carbonate of soda was recommended as the alkali for hydroquinone instead of the usual hydrate. Mr. Faulkner said that, development being slower, a finer grain and a better negative would be the result. The discussion having turned on fixing, Mr. Cembrano expressed the belief that fading of silver prints was often due to insufficient fixation. For negative work, a dirty hypo bath was often the cause of stained or yellow negatives. Mr. J. D. Gibson said that climatic conditions also affected the permanency of albumen prints. Photographs which he had made in Madras, where the climate was dry and hot, had faded, while others, done at the same time and under the same conditions, which he had sent to England, had stood the test of time well. His experience of the climate in Ceylon, which was damp and hot, was that it also caused prints to fade. He added that want of permanency was due as much to unsuitable mounts and mountants as to insufficient washing out of the hypo. A member having asked whether prints on gelatino-chloride paper required as much washing as albumen prints, Mr. Ardaseer replied that the former required more, the paper being thicker and the hypo penetrating more into the gelatine. The discussion fixed for the evening on *Improving Faulty Negatives* was opened by the Chairman, who said that there were a number of ways of improving faulty negatives, but that, whenever possible, he recommended taking another one. Covering the back of the plate with collodion, containing some aniline dye, such as aurine, was an excellent plan, whose parts covering the over-dense spots of the negative could be scraped away. Mineral, or tissue paper was also often used in a similar manner; by means of a stump and blacklead used on them, the light could be retarded on some parts of the plate. Sometimes a negative could be greatly improved, especially if a very flat and thin one, by making a transparency from it, and from this a negative; by suitable exposure and development, the contrast could be very much increased. Intensifying the negative was often resorted to by some workers, while others preferred getting great density by development, and then using a reducing agent. For platinotype, Mr. Willis had found that, printing under signal-green glass, the quality of the resulting print was much altered; it was eminently suitable for hard negatives, as printing under iris glass gave much softer images. He (the Chairman), had obtained a piece of signal-green glass, but the colour appeared to him to be a peacock blue by daylight. Mr. Ardaseer said that was so, but by gas or oil light the colour would show as green; if examined in the spectroscope, it will be found to transmit nearly no other rays but the green. The Chairman then announced that the winter session of the Club would begin on October 10, and that the nights of the meetings would be altered to Mondays, at eight o'clock, the chair being taken at half-past eight p.m. This change had been found necessary in order to secure the use of a larger room, the present one being inadequate, owing to the increased number of members.

South London Photographic Society.—September 3, Mr. Maurice Howell (Vice-President), in the chair.—The President (Mr. F. W. Edwards) read a paper on the *Life and Works of George Tinworth*, the famous terra-cotta sculptor, illustrated by a fine collection of forty lantern slides, which was much appreciated by the members and friends (150) present. Many requests for the repetition of the lecture have already been received by the President, who has consented to do so, and to increase the number of illustrations to sixty. It was announced that the judging of the prints from negatives on Paget plates was deferred until the next meeting.

Tooting Camera Club.—September 8, Lantern night.—Slides of English, Scottish, and Continental views were exhibited by means of the President's new limelight lantern to a large number of members and friends. The Paget Prize Plate Company kindly sent a framed enlargement of instantaneous pictures, taken on their plates, for the Club-room; also sample packets of their plates, which were distributed to the members for trial.

Croydon Microscoptcal and Natural History Club (Photographic Section).—September 9, Mr. Carter in the chair.—In addressing the meeting, the CHAIRMAN said they were brought together that evening to discuss and receive the opinions and ideas from the members as to the arranging of the coming winter session. Mr. E. Lovett, the President of the Club, who was present but unable to take the chair owing to other business calling him away, intimated to the members that the Institution Committee had made them an offer of their committee-room, to be converted into a dark room and meeting-room, in the place of the dark room they now had, and which could not be used on account of being so damp. The idea was well received by those present, and Mr. GOODE proposed, and Mr. WALLER seconded: "That it was the opinion of the Photographic Section of the Club that it would be a great boon if the committee-room could be hired for the purpose of a dark room, to be always available for the use of members." The CHAIRMAN then said that that proposition would be placed before the General Committee of the Club on Wednesday next, to receive their consideration. Mr. Carter then called attention to a new question box which the Club now had, and hoped the members would avail themselves of it. Suggestions were then received from the members present for the coming winter meetings, and will be considered and arranged in due course by the Photographic Sub-Committee.

Chorley Polytechnic Photographic Society.—In connexion with the Polytechnic recently established in this town, a camera club has been formed, and will be known by the name of the Chorley Polytechnic Photographic Society. The premises, which are at present undergoing extensive alterations, are conveniently situated in Fellery-street, almost in the centre of the town, and it is expected that the dark room will be ready for use in the course of a few days. At the meeting held on Wednesday, September 7, the following gentlemen were appointed officers:—*President:* Mr. J. T. Brierley.—*Vice-Presidents:* Messrs. H. R. Dorning, R. Berry, and W. Dornan.—*Treasurer:* Mr. R. Gill.—*Secretaries:* Messrs. Jas. G. Welch and Wm. Wareing. Judging from the attendance, and the number of members who have enrolled themselves at the various preliminary meetings, we have little hesitation in saying that there is every prospect of this becoming a most successful organization. Any one interested, and desirous of becoming a member, is invited to send his name to either of the Secretaries, from whom all particulars may be obtained.

Derby Photographic Society.—The above Society had one of their very enjoyable outings on Saturday last, September 10, going to Melbourne, which, with its quaint old church and picturesque lake, offered good opportunities for camera work. Through the courtesy of Mr. Fane, his extensive grounds, laid out in the Dutch style, with ancient yew-tree hedges, were opened to the Society. The light being excellent, some good views were obtained, and the return journey was made in the early evening. The Society had as a guest Miss Catherine Weed Barnes, of New York, who has also been entertained by Messrs. Keene and Scotton, who accompanied her to Haddon Hall, Matlock Bath, and Wingfield Manor, and a number of exposures were made. These excursions have been much enjoyed, and it is to be regretted that they are so nearly at an end.

Lewes Photographic Society.—The annual meeting of this Society was held at the Fitzroy Library on Tuesday evening, September 6, under the presidency of Mr. Tunks. Mr. BEDFORD, the Hon. Secretary, read the following report:—"There are at present forty members on the books; nine new ones have been elected during the year, and seven have resigned. Ten ordinary meetings have been held during the year, and have been fairly well attended. The excursions have been so badly attended that it is contemplated to discontinue them unless

they receive better support. The Treasurer's report shows a balance in hand of 1*l.* 8*s.* 4*d.* It is with much regret that the Council have to mention the loss the Society has suffered by the resignation of Mr. J. G. Braden, who has held the position of President since the formation of the Society, he having left the town; also their regret at the loss of so energetic and useful a member as Mr. Percy Morris, who has likewise left the town, but they are pleased to know that both these gentlemen will continue as members of the Society. Finally, the Council wish to thank the Press, local and otherwise, for their kind notices of meetings, excursions, &c., and for kindly sending copies of their papers." The report was adopted, and Mr. Tunks was unanimously elected President. Mr. Wightman was appointed Vice-President. Mr. Constable was elected Hon. Secretary in the place of Mr. Bedford, who resigned the office, having found it impossible to give the amount of time required to carry out the duties; and Messrs. Funnell, Young, Carpenter, Bedford, and Curtis were elected on the Council. A vote of thanks was passed to the Paget Prize Plate Company for a framed enlargement of snap-shot pictures taken on their plates, and for sample packets of plates sent by them for trial, which were distributed to the members present, who promised to report on them at a subsequent meeting. A new style of printing frame, the Bynoe, sent by R. & J. Beck, was shown, and generally considered to be a decided advance in printing frames. All communications for the Society should now be addressed to the Secretary, Mr. H. B. Constable, 5, East-street, Lewes.

Manchester Photographic Society.—September 8, Mr. A. Brothers occupied the chair.—Mr. W. H. Farrow (Hon. Secretary) showed Beck's Bynoe printing frame; a very compact and apparently efficient improvement on the old wood frame. Mr. Alan Garnett introduced a novelty he had obtained recently in Paris. This was a substitute for the lime cylinder, to be used for the oxyhydrogen light. It was composed of a preparation of magnesium, in the form of a small disc (about the size of a sixpence); a platinum pin in the edge enabled it to be fixed in a suitable holder on the ordinary lime pin. Mr. Garnett stated he used it with a blow-through jet; with a mixed jet it did not give as good a light, the reason of which he could not explain. When the light was once adjusted, no further attention was required, and the disc was unaffected by the ordinary atmospheric moisture when not in use, qualities which were of great advantage over limes. As far as Mr. Garnett could at present tell, the substitute was fairly durable, and each disc would last a considerable time. A rough trial was made in the lantern with the new disc against lime, a blow-through jet being used, and, as well as could be judged, the lights were equal, some being inclined to award the new light superiority in purity. Mr. Garnett had with him one of Steward's latest jets, fitted with every requisite adjustment by screws or racks, and also with a bye-pass cut off tap to the blow-through jet—a very valuable addition, especially when used in conjunction with the lime substitutes for enlarging, or when the full light was only required at intervals. Messrs. Blakeley and Evans were elected Auditors of the past year's accounts. The Hon. Secretary announced that the Photographic Society of Great Britain had reserved the evening of October 19, during their annual exhibition, for a display of lantern slides by the members of the Manchester Society, and requested members to send in slides, so that a good selection could be made for that purpose. Mr. Smith, of the Eastman Company, was present during the evening in a private capacity, and he contributed much to the interest of the meeting by showing a collection of holiday snap-shots.

Rotherham Photographic Society.—Tuesday, September 6, Dr. F. B. J. Baldwin (President) in the chair.—One new member was elected. The Bynoe printing frame was introduced. The arrangement for holding the paper was much approved, but the question was asked as to the risk of the print moving in the larger sizes. Information had been received relative to the Hill-Norris collodion plate, which had made its appearance during the month. Particulars of several photographic specialities were laid before the members. The fourth excursion of the season was arranged to take place on Friday, September 16. The destination is Wingfield Manor, Derbyshire. The remainder of the evening was taken up in a profitable consideration of "questions," of which there were a considerable number. One member desired information as to the yellowing of one of the chloride of silver emulsion papers, and it was thought that, in the process of toning, the addition of fresh gold to an almost exhausted bath might have brought about the degradation.

Sheffield Photographic Society.—September 6, Mr. E. J. Chesterman in the chair.—The new rules of the Photographic Exchange were brought forward and thoroughly discussed, and satisfactorily arranged, when fifteen members gave in their names to join. The Secretary laid upon the table for inspection a new printing frame by Beck & Co., and Mr. Crowder showed a neat contrivance to act as printing frame in case of emergency. Several members gave very good reports of the Paget Prize Plates handed round at the last meeting, showing negatives and prints from same. The date for the receipt of pictures for the annual competitions was postponed until November 14. Mr. E. Beck opened the discussion on *Instantaneous Photography*, which induced a deal of valuable information.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

PHOTOGRAPHY BY RULE.

To the EDITOR.

SIR,—In my letter published in your issue of the 9th inst., I inadvertently stated that the exposure varied as the focal length of the lens. Obviously I should have said as the *square* of the length.

The word "false-lying" is a printer's error for *falsely;* and likewise the word "instrument" occurs where I have used the plural, *instruments.*

Hoping you will allow these corrections to appear,—I am, yours, &c.,

The Arts Club, Manchester, September, 14, 1892. R. C. PHILLIPS.

To the EDITOR.

SIR,—Mr. Bedding, in his reply to Mr. Phillips on September 2nd, says "that in photography, a little of one's own experience conveys much more instruction than a great deal of another's." But do not all photographic students of necessity have to rely more or less upon others' experience before being able to adventure their own? As Mr. Bedding, in condemning exposure tables and actinometers, &c., advises the beginner in photography to ignore other peoples' experience, should he not logically extend the same advice to them as regards the composition of developers, developing, printing and toning, &c.?—I am, yours, &c.,

London, September 8, 1892. W. MORRIS.

Mr. Bedding's reply to the above, and to Mr. Phillips's letter appearing in the JOURNAL of last week, is as follows:—

"Apparently Mr. Phillips is not content to place the beliefs of his good men and true (whoever they may be) as to the value of aids to exposure in the scale against the work of the majority of photographers who do not use such aids, as he somewhat lamely says that he cannot gauge the work of this majority because he is not ubiquitous, and they will not show him their failures. This is pretty fencing; but Mr. Phillips should know perfectly well that it is no rejoinder. Trial and error is the system upon which, so far, most of the world's photographs—successes and failures—have been made. What, then? Does Mr. Phillips guarantee an immunity from failure under his 'quantitative element' system? Where are the successes of that 'quantitative element' system? and why is it that, although several weeks have elapsed since the publication of the paper on 'Photography by Rule' in three photographic journals, not one unprejudiced person in the whole of the photographic world has taken the trouble to criticise my contentions? Mr. Phillips says he is unbiassed, and I will accept his assurance; but I believe he was taking photographs for many years before the advent of Messrs. Hurter & Driffield. Now that he has found salvation at Widnes, I should like to know if he is agreeable to inform his brethren through these pages that he has only just recently found out how to properly expose a plate?

"I perceive that, in attacking the constancy of the factors considered in exposure calculations, I have failed to convey my precise meaning to Mr. Phillips, the fault of which I admit is chiefly my own. Let it, however, be true that the principles of the instruments assume the variability of the factors with which they deal, will Mr. Phillips tell us what kind of result we are to expect from varying a series of uncertainties? Do gelatine plates increase or decrease in sensitiveness by keeping? Or are they unaffected in that respect? Under what system of exposure calculations is the actinic power of the light accurately expressed? Again, as to Nos. three and four of the principles of the instrument Mr. Phillips defended (and which, by the way, I have not yet attacked), is the area of aperture of the diaphragm in relation to focus always correctly rendered? and, moreover, are all lenses of equal aperture and equal foci on an equality of rapidity? In short, are the values of these factors so accurately known at the time of exposure as to assure a proximately correct exposure? and if the knowledge to be gained by correctly rendered factors is only of approximate value, of what use is it when all or any of the factors are erroneously estimated? Surely, under the latter conditions, I am justified in doubting if the knowledge is likely to be of real assistance, while as under the most favourable circumstances Mr. Phillips admits it to be only an approximation, the quantitative element would not appear to take one any nearer the attainment of correct exposure than the method of trial and error.

"Until there is some ground for alleging that a man who fails to master exposure by trial and error will find his difficulties removed by adopting aids to exposure, I consider Mr. Phillips's inference as going too far. What would be the use of the youth who had failed with his own brains adopting aids which Mr. Phillips concedes only give approximate results? I always thought that in exposure accuracy was a desideratum, but according to Mr. Phillips's method it is not obtainable. Why then advise one who is incapable of succeeding with trial and error to take up a method which still leaves the door open to error? As to Mr. Phillips's challenge, may I ask him to define the circumstances under which a photographer is likely to be working with plates 'of whose speed he has no idea.' Personally, I am quite content with trade speed descriptions of plates as a guide, and so are most, if not all, photographers, I believe. In his first letter Mr. Phillips says that he has observed an operator of long experience and judgment demand trial plates and rectify his error on the second or third trial, while the novice requires a dozen or more. Quite so; but, when the novice has emerged from his novitiate a trial plate will suffice. Mr. Phillips makes me say that it is not advisable to know the speed of the plate one is working with, but to *look at the focussing screen* and find out by trial and error. It is a pity that Mr. Phillips's admiration for Messrs. Hurter & Driffield's work should be responsible for such distortions of an opponent's views as this. I said nothing of the sort.

"Mr. W. K. Burton's article as to the value of exposure tables, from which Mr. Phillips quotes, was, it seems, written ten years ago, and yet in all that time we have only got so far as 'approximate' results. This is hardly comforting for the students 'who,' Mr. Phillips says, 'have better times in store than their predecessors have had, if they will but make intelligent use of their experience.' They do not appear to have

profited much by the exposure tables of the last ten years or so, otherwise why were Mr. Phillips's letters written? That gentleman asks me if I have tried to discover whether the authors of exposure tables and instruments are practical photographers? On Mr. Phillips's assumption that they are, what is still more extraordinary to find is, that any advocate of these tables and instruments should be a practical professional photographer.

"I think Mr. Morris will find his letter answered in the course of the above reply to Mr. Phillips."

THE DECAY OF PROFESSIONAL PHOTOGRAPHY.

To the EDITOR.

SIR,—I have read all the correspondence in your JOURNAL on your leader of August 5 on the "supposed" decay of professional photography, and, seeing that you have published some letters from professionals in the cities, I thought you would like to know what some of us smaller men—country professionals—think of your article.

Well, Sir, we think your statements are very much exaggerated. You say that the professional "puts out" nearly all his work, but I reply that we country photographers don't do our business in that way. For myself, I have been in business for twenty-two years in the same town, and my business is growing larger every year. I have worked the collodion process for years, and when dry plates came in I made my own, and did not buy any for six or seven years. I also worked the Lambertype, chromotype, platinotype, and other methods of printing; have made some of my own enlargements; this is the only process in my business that has been partially "put out." I have had apprentices serve for five or six years each, and can name some of them that are turning out photographs, to put it mild, not inferior to most of your city photographers. Now, Sir, I am not saying this to boast, but we do think your article is a libel on the professional photographers, and that has made it necessary to contradict your statements in order to defend ourselves. As far as a large number of country photographers are concerned, and I have made a great many acquaintances during my twenty-two years amongst them, I could not think of one where your article would apply. No, Mr. Editor, *you must recant.*

Again, how is it that all the good photography is not found in London and other large cities, where all the advantages of scientific training can be taken advantage of? I don't think, Sir, you would be bold enough to say that the average of first-class photographers is greater in London than elsewhere. If that is the case, I must have been unfortunate in coming across a goodly number of second-rate ones when I visited the great city. But, Sir, please don't think that we depreciate any opportunities of improvement. We wish we had some of them to help, but certainly not to replace the years of apprenticeship.

One more question: If the amateurs are making such headway and photography learnt without apprenticeship, how is it we do not see more of their work that would be fit to put on the market for sale? I see a good deal, but very seldom any that would stand the test of being offered to the public in the ordinary way. Perhaps there may be one in the 10,000, as in A. Lévy's letter of August 26.—I am, yours, &c.,

September 10, 1892. A COUNTRY PROFESSIONAL.

THE NEW DEVELOPER.

To the EDITOR.

SIR,—Upon reading your remarks upon my last letter I communicated with Mr. Hauff at Feuerbach, the manufacturer of amidol and metol, and find from his reply that, whereas metol is to be had everywhere in Germany, amidol alone has been placed on the English market, but for trade reasons is not sold here—the reverse being the case with metol.

He has, however, supplied me with some amidol, and on trying it I have found your remarks on it in your leading article fully justified. It develops clean and thoroughly all the different brands of plates which I have hitherto had time to try, including Eastman's films—but, beyond being a single-solution developer, has no advantage over metol, if indeed that be an advantage.

It has, however, one drawback—especially for a lady—that it stains the fingers dark brown, much the same as pyro silver in developing a collodion plate—and I confess I like keeping my hands tidy if possible. When working wet collodion I wear white kid gloves that have been used at evening parties, and which have become easy from wear, with, of course, the long arm parts cut off; but I think at best they are awkward, and I should prefer a developer such as metol, which does not stain.

The maker of amidol, in writing to me, especially recommends it to be used as follows, particularly for travellers:—

Water	2 ounces.
Sulphite soda	48 grains.

This solution can be made up in quantity anywhere, and keeps perfectly. When required for developing add to the above quantity of solution five to six grains of amidol, which, to save weighing, can be sufficiently accurately measured by means of a small horn spoon. It will dissolve readily, and develop five or six plates in quick succession, which, after being slightly rinsed in clean water, are fixed in the acid fixer—four parts hypo to one part bisulphite.

No alum bath is necessary; I generally use the fixing cartridges, consisting of the two salts mixed, and sold at a cheap rate. Two of these dissolved in twelve ounces of water give an acid fixing bath which will last a long time, and remain limpid till quite exhausted.

Darmstadt, September 10, 1892. ETHEL CONSTANCE MAY.

CYANIDE OF POTASSIUM.

To the EDITOR.

SIR,—In your issue of September 9 you refer to a paper read by Dr. Kayser upon the above substance, in which he states that the "so-called potassium cyanide of commerce usually contains a very large proportion of sodium cyanide." We have been manufacturers of cyanide of potassium for thirty years, and are, we believe, by far the largest makers in this country, but our product is, and always has been, quite free from cyanide of sodium. We only supply cyanide of sodium, and cyanide of potassium and sodium, when specially asked for.—We are, yours, &c.,

JOHNSON & SONS.

23, *Cross-street, Finsbury, London, E.C., September* 13, 1892.

THE "FRENA" HAND CAMERA.

To the EDITOR.

SIR,—We shall deem ourselves greatly favoured if you will kindly announce in your next issue that we have been appointed by Messrs. Beck, special West End agents for the sale of their new "Frena" camera and films, and that we hold a very large stock of both ready for immediate delivery. It may also interest your amateur readers to know that we give practical demonstrations to purchasers, which naturally tends to ensure their success.—We are, yours, &c.,

Pro THE LONDON STEREOSCOPIC AND PHOTOGRAPHIC COMPANY, LIMITED,
London, September 9, 1892. BUTLER HUMPHREYS.

PHOTOGRAPHY AND THE ILLUSTRATED PRESS.

To the EDITOR.

SIR,—You have several times used strong terms respecting those who pass off other person's work as their own.

In the *Illustrated News* of August 27 is a full-page reproduction of a photograph entitled *Cool Waters*, described as being by Morgan & Co., Bournemouth. The original negative was taken by myself in 1886, and an enlargement, 24 × 18, was, as some of your readers may remember, in the Photographic Society's Exhibition in Pall Mall in that year, and it was also shown at Dundee, where it took the silver medal (highest award).

Morgan & Co., as successors of the firm of which in 1886 I was a partner, have a right to publish the photograph, but not to describe it as being by themselves.—I am, yours, &c., HENRY WHITFIELD.

1, *Bellevue, Clifton, September* 12, 1892.

A SOCIETY FOR FOREST GATE.

To the EDITOR.

SIR,—In reply to the query appearing in your last issue as to a Society for Forest Gate and Stratford, we are quite close to this district, and have a good number of members residing there. Our roll of members counts ninety, which speaks well for the success of the Society. Our subscription is five shillings per annum. Our winter season commences in October. Informal meetings are held every Saturday evening this month at eight o'clock, and we shall be pleased to see Mr. Wilton or any other gentleman wishing to join a good society.—I am, yours, &c.,

ALBERT E. BAILEY, *Joint Hon. Sec.*

Rosebank, Southwest-road, Leytonstone.

Exchange Column.

Will exchange 12 × 10 burnisher, oscillating bar, for good portrait lens of ten-inch focus, or more.—Address, J. HORTON, Central Studio, Caroline-street, Cardiff.

Will exchange fireplace accessory (by Seavey), in good condition, for good small rectangular table, preferably double-ended.—Address, J. T. GENTNEY, 6, South-parade, Huddersfield.

Exchange microscope (cost 45*l.*) for screw-cutting lathe to value of about 15*l.*; also 5 × 4 No. 4 regular Kodak, for gentleman's gold lever watch and chain.—Address, A. VALENTINE, 30, Danbury-street, London, N.

Enlarging lantern, with eight-inch condenser, and portrait lens oil lamp, all complete, costing 13*l.*; will exchange for one of Watson's new Premier portrait lenses, costing 9*l.* Address, GIBBS & Co., Middlesbrough.

Exchange for a hand camera or a quarter-plate rapid rectilinear lens, THE BRITISH JOURNAL OF PHOTOGRAPHY from July, 1883, to December, 1885; the year 1889; 1890 from February; 1891 complete; and 1892 up to August; also the first fifteen numbers of the *Magic Lantern Journal*, except Nos. 3 and 7.—Address, J. GRIMSHAW, 16, Dale-street, Haslingden.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," *2, York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," *2, York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

H. J. Davis, Penrith.—*Church Parade of the Royal Westmoreland and Cumberland Yeomanry Cavalry*, 1892. *Eden Hall troop of Royal Westmoreland and Cumberland Yeomanry Cavalry at Grestoke Castle, May*, 1892.

G. DAINGER.—We should be happy to consider the matter if you will send us the articles. You did not enclose your address.

C. EGERTON.—The work you name can probably be seen in the Free Library of the Patent Office, Southampton-buildings, W.C.

A. HORTON.—Having arranged the lens to its best advantage, take it to a competent optical brass-turner and state your requirements.

W. A. C.—1. Caramel, if used as a backing, will obviate halation. 2. The plates you name may be obtained already orthochromatised.

S. H.—The spots appear as if due to either floating particles of matter on the surface of the bath, or settling on the paper while the surface was still moist.

D. T. C.—The whole of the specimens sent are fairly good as photographs, but not as pictures. In every case the camera was placed far too near the sitter; hence the unpleasant appearance.

C. WHITE.—1. The first-named lens stopped down is perhaps preferable. 2. Yes, undoubtedly. 3. Yes. 4. The print is probably overtoned. 5. The lighting is all that could be desired.

A. LEVY (Paris).—1. We should be pleased to have your experiences. 2. The appearance of the paper is a sufficient guide. If you have the requisite light surface, it matters but little whether it is obtained by a single or a double operation.

EXPERIMENTALIST.—Gum, dextrine, albumen, and all colloid substances of that character, when treated with bichromate of potash and exposed to light, become insoluble, or non-absorbent of water, in the same manner that gelatine does.

C. MALCOLM.—If by "porcelains" you mean pictures on opal glass, the best and most general way of producing them is by the carbon process, single transfer. Take reversed negatives, and develop the carbon prints direct upon the glass, which, of course, has been perfectly cleaned. No substratum is necessary.

LOUIS (Paris).—The print forwarded is not a photogravure, but a collotype. It is an exceedingly fine specimen of that process. Prints of this kind can be produced at a much lower rate than photogravures, but to produce them of the quality of this one would necessarily cost considerably more than the general run of collotype work.

E. W. WARREN.—Wake's work on *Colouring* was the best published, but is now out of print. It is possible that you may obtain a copy of it by advertising for it, or the volume of THE BRITISH JOURNAL OF PHOTOGRAPHY in which it appeared several years ago. Failing that, we should advise you to get a few lessons from a skilful colourist.

SILVER.—Probably if you had procured the sample of potash we recommended, which may be had at any operative chemist's, you would have succeeded better; but when you speak of edging the plate with putty, we quite perceive that you have no idea of the cleanliness and niceties of the process. If with the right kind of potash you do not succeed, you will find it cheaper to send the glass to a professional silverer.

A. C. (Edinburgh) wishes to know how to produce "negatives on dry plates so that they cannot be distinguished from wet collodion."—We do not know. The plates supplied specially for photo-mechanical work, and slow plates developed with hydroquinone, have very much the character of those by wet collodion. But the best of them would not for a moment be mistaken by any one at all familiar with the collodion process as being produced by that method.

W. MALONY.—There are several different forms of presses employed in collotype printing besides the power machines. The ordinary typographic press is used considerably in this country. So also is the litho press. Special presses are made for collotype work, in some of which the pressure is applied by a roller; in others by means of a scraper, as in the lithographic press. It matters very little how the pressure is obtained so long as it is applied evenly and is under control.

W. HILL says: "Would you let me know, if I took the view of a church or, in fact, any photograph of a personage, and had the print copyrighted, could any other photographer take the church or person without infringing the copyright, or does the copyright just protect the print only?"—In reply: The copyright protects the particular print only that is copyrighted. Anybody else is perfectly at liberty to take the church or the personage from exactly the same standpoint as you did.

T. E. B.—All retouching mediums, the formulæ for which have been published, are more or less affected when the negatives are varnished. This remark applies, though less perhaps, also to commercial ones. The better the medium suits the requirements of the retoucher in his work, the more liable it is to be acted upon after varnishing. As a shilling bottle of the best recognised medium is sufficient for several hundreds of negatives, you will find it more economical to purchase it than experiment in making it for yourself. However, Canada balsam, thinned with turpentine, forms an excellent retouching medium. Other formulæ will be found in back volumes of the JOURNALS and of the ALMANACS.

A. F. M. writes: "I am anxious to take a photograph of a golf club swinging, as I wish to get the true curves. I have tried attaching a flaming fusee to the head of the club, but the flame blows out, owing to the rapidity of the swing. Of course, I do it in the dark, and what I wish is a curve of light on a black background. It has been suggested that I should fasten a globe of polished metal to the club head, and take the photograph in sunlight; but, besides other objections, I think leaving the lens open so long would entail hopeless fog, and I write to ask if you could put me up to any plan by which I could attach a brightly burning or glowing light to the club head without its blowing out. Would luminous paint impress the plate at the speed a club travels, which is very great?"—Luminous paint would be useless; a small electric lamp might serve, but the motion of the club would have to be regulated accordingly.

F. E. G. says: "I thank you for your reply through the JOURNAL with reference to the copying difficulty. However, your remarks do not assist me; I am afraid I did not explain to you clearly where I am in fault. If I wish to make a copy, not necessarily of same size, but approximately, and I plant my camera about six or seven feet from object, in focussing this is what happens: If I adjust the ground glass by moving it forward, I can get the object clearly defined on the ground glass; but if, instead of moving the screen forward, I move the lens back, the object will not become clear. As I move it back it certainly grows a little more into focus, but after passing a certain point it then works out of focus again. If this is so, then I am afraid the same defect will (in a smaller degree) arise in taking groups with such a camera; in fact, I have, before I attempted any copying with it, thought there was not very good definition, and was inclined to blame the lens. I feel sure many of your readers will have experienced the same difficulty, and I would like to know what is the best thing to do, as I cannot afford to throw away the camera and get a new one?"—Your difficulty will vanish if you will realise that in focussing inwards with the lens the object should also be moved.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—October 17, *A Chat about the Eastman Products*, led of by Mr. Arthur C. Baldwin.

THE meetings of the Hackney Photographic Society are now held at 206, Mare-street, Hackney, and not at Morley Hall, as before.

CROYDON CAMERA CLUB.—Special whole-day excursion, Saturday, 17th inst., conducted by the Vice-President, Mr. B. Gay-Wilkinson, to Limpsfield, Pains' Hill, and Hurst Green.

MISS CATHERINE WEED BARNES, of New York, is to address the members of the London and Provincial Photographic Association on September 22 on *Photographic Limits*. Visitors will be welcome.

PHOTOGRAPHIC CLUB.—September 21, *Photographic Fallacies;* at 9, Special General Meeting. 28. *The Object of Photography* (Miss Catherine Weed Barnes). Outing Saturday next, September 17, Kew and Strand-on-the-Green. Meet at Kew Station at half-past two.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1893.

EDITED BY J. TRAILL TAYLOR.

THE ALMANAC *for* 1893 *is already in course of preparation, and we shall be happy to receive contributions from those who in former years have enriched its pages with the results of their experience and practice in the photographic art. Not less cordially, also, do we invite the newer supporters of* THE BRITISH JOURNAL OF PHOTOGRAPHY *and its* ALMANAC *to include themselves among the contributors to the Annual which for many years past has been highly esteemed for the valuable writings of so many able photographic workers.*

As we were compelled last year to omit several interesting articles from the ALMANAC *on account of the late dates at which they were received, we should be glad if intending contributors would endeavour to send us their articles as early as possible.*

NEW MONTHLY SUPPLEMENT.

IMPORTANT NOTICE.—*With the* JOURNAL *of Friday, October 7 next, and on the first Friday of each succeeding month from October to March inclusive, we shall issue a special gratis supplement, devoted to the interests of the makers and users of the optical lantern, in which every phase of the subject will be treated by the ablest authorities. This step, which has been in contemplation for a considerable period, is necessitated by the increasing popularity of the lantern in its numerous applications, scientific and domestic.*

CONTENTS.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1690. Vol. XXXIX.—SEPTEMBER 23, 1892.

As previously announced, we propose, during the months of October, November, December, January, February, and March, issuing with The British Journal of Photography a gratis supplement, devoted to the interests of the makers and users of the optical lantern and its numerous applications. The first supplement will appear with the Journal of Friday, October 7th next.

The growth in utility and popularity of the optical lantern, its increasing importance as an adjunct to amateur photography, its manifold advantages to the photographer, the scientific investigator, the lecturer, and many others, more than justify the institution of a special department of The British Journal of Photography in which the topic in all its phases can be exclusively treated, besides rendering the interests of the many commercial firms now engaged in the manufacture of lanterns and their many accessories so considerable as equally to demand increased facilities for their separate representation.

We shall be happy to receive communications of interest relating to the lantern and its cognates for the pages of the supplement, in which we shall also be glad to notice novelties and improvements in apparatus. In short, it will be our endeavour to deal with the lantern from every standpoint in the most comprehensive manner possible.

ABNORMAL EFFECTS IN LIGHTING.

While writing this, we have on our table a photograph, which might be termed a species of "mystery picture," taken by Lady Gertrude E. Molyneux, of Croxteth. The subject is *The Alps from St. Gervais*, and from memoranda on the back we find that it was taken "by moonlight," with an exposure of nine seconds, the lens, a rapid rectilinear, working at *f*-8, its full aperture. The date on which it was taken was July 3, and the hour was nine o'clock p.m. We have here all the *data* requisite for the investigation of this phenomenal photograph, in which we see the moon itself in the heavens, about two degrees above the mountain ridge in front.

The first noticeable feature on scanning the picture is that several portions, which could not by any possibility have been illuminated by the moon, are shown fairly well lighted, and with some detail, and this at once might be held as disposing of the idea as to any direct lunar influence having been exercised upon the illumination of the subject, for a view taken by moonlight, and showing detail, implies that the moon is elsewhere than directly in front of the camera. Besides, we, and every one who has attempted photography by lunar light alone, know full well the absolute impossibility of obtaining a photograph of a terrestrial scene by an exposure of nine seconds, or, for that matter, of nine minutes, even with a quicker acting lens than that employed on this occasion.

Where, then, is to be found a solution of what some of our good friends in the Midland provinces have been disposed to regard as a mysterious photograph? In our estimation there is no mystery in the matter at all, or difficulty in the solution. It was taken on July 3, at nine o'clock in the evening. Now, moon or no moon, the obtaining of a photograph so very soon after sunset would prove a feat not beset with any difficulty in this country, and still less, we think, would it be so in the high Alpine region, which may be assumed to be 44° north latitude. At nine o'clock in an almost midsummer evening, we have obtained presentable photographs in the latitude of London, where, during a series of several days, and omitting seconds, the sun does not set until nineteen minutes past eight o'clock, the date of the taking of Lady Molyneux's photograph (July 3) represents a difference of little over one minute from this. Hence it is very easy to conceive of the atmosphere being so well illuminated for this brief period after sunset, especially in the vicinity of lofty, snow-clad mountains, as to render photography quite practicable for a time, even after the disappearance of the orb of day.

It may be that in a case such as that just described the mere visual power of the moon, especially when it is a full moon sailing in a clear atmosphere, will, in a measure, cheat the senses into the belief that its luminousness far transcends in actinic energy that of a seemingly feebly lighted sky.

Bearing in mind that the lunar light does not exceed that which would be radiated from a cloud the same angular dimensions of the Queen of the Night, it is also a fact that, under some conditions, the actinic power of the sun itself, even when its rays are thrown direct upon an object, is so feeble as to be quite overpowered by the grey sky.

One of the finest examples of this occurred in our own experience some years ago. It happened, when on a visit to a group of islands situated in 59° north latitude (just beyond the most northerly point of Scotland), that we took occasion to obtain a portrait just before sunset, and when the sun, then in the north-west, was sinking with an *entourage* of crimson clouds. By this, as a dominant light, one side of the sitter was brightly illuminated. The process was wet collodion, the proportion of iodide to bromide in the collodion being about three and a half

to one. On developing the image it was found that the shadow side of the face, that which was lighted from a grey easterly sky, showed a denser deposit than that obtained from the direct solar rays. This was quite easily accounted for by the fact of the setting sun having been shorn of its actinic power in a degree far transcending that of its luminousness.

On mentioning this incident to two friends, one of whom was the late O. G. Rejlander, the latter stated that he had had a precisely similar experience on one occasion, the lights and shadows being reversed.

We have lately carried a cognate of this idea a little further, and applied it to the taking of portraits in a private room, when, as is so frequently the case, the sitter has to be placed at the side of a window, a concomitant of which position is that one side of the face is lighted, the other being deep shadow, except in so far as it is illuminated by the light radiated from the walls of the apartment. On lighting up the dark side by the light obtained by burning a few inches of magnesium ribbon, we found no difficulty in so subordinating the daylight illumination as to effect a reversal, causing the outer, or naturally lighted, side to be the shadow side, the inner side being that from which the dominant light proceeded. The hint here thrown out may be profitably utilised by those who have the leisure and inclination to follow it up.

THE POSITION AND PROSPECTS OF PROFESSIONAL PHOTOGRAPHY.

It is so often the fate of those who, with the best of intentions venture to pass in review the actions, tendencies, or shortcomings of a section of their fellow-men, to be misunderstood, that we shall not complain of not having carried with us the entire number of our professional friends who recently took advantage of the opportunity afforded them by our correspondence columns to discuss the conclusions of our article of August 5, on "The Decay of Professional Photography." In terminating the correspondence, however, we are glad to note that several of them appreciated the motives by which we were inspired on that occasion, and the remainder, we are convinced, would have done so had they, as one correspondent suggested, read what we wrote without bias; for, although our strictures may on first acquaintance have read rather unpleasantly, it is needless, we are sure, to remind our friends that our remarks were conceived in the same spirit which has always animated this Journal in its relations with the profession—that is, one of the warmest solicitude for its well-being.

In describing the system under which very many modern photographers conduct their businesses—that of "putting out" a great deal of their work—we were guided by our own knowledge and experience, which we are hardly disposed, either as regards length of time or of area, to place below that of any of our correspondents; and, of course, we allowed that there were numerous exceptions to the rule. The extent to which retouching, printing, and enlarging, and other departments of practical photography are delegated by the photographer to trade houses who make a speciality of these classes of work, clearly indicates that in such studios the opportunities of a youth for acquiring any knowledge beyond the production of the negative are retarded; but where it is otherwise, and the work is done in the photographer's own establishment, we should be the last to assert that a youth could desire a better field for the study of portrait photography, from the exposure of the plate to the production of the finished print.

Our doubt as to the majority of photographers' studios being conducted on the latter plan is, after all, the chief point at issue between ourselves and one or two of our friends, and we fear that, notwithstanding their individual beliefs and impressions to the contrary, we must adhere to our original proposition, derived, as we have hinted, from no inconsiderable observation and experience. Nobody would be more pleased than ourselves could we have reliable evidence that we were mistaken, inasmuch as it would in a large measure disprove the theory that professional photography is in the depressed condition it is generally supposed to be. One argument more than another seems to us to support our view of the matter, and that is, that if, contrary to our belief, the numerous departments of photography are as a rule executed on a photographer's own premises, the magnitude of the average business far exceeds what it is commonly supposed to be.

The studio photographer is, we believe, more often born than made, and the artistic feeling, the tact, and the other mental qualities necessary to success are, if also ingrained, only cultivated to perfection in the studio, and are neither to be acquired nor developed in the technical schools which so many have recently been advocating. It has, however, never, to our knowledge, been suggested in any proposed scheme of technical instruction that the experience to be gained in a studio could so far be supplied elsewhere; and hence we are agreed with a correspondent as to the importance of a separate study of both. The object of technical instruction is, as we understand it, to impart to the young photographer a knowledge of ancient and modern photographic processes, as to which, in comparison with his Continental *confrère*, most people consider him behindhand. This knowledge cannot be gained in many photographic studios. One of our correspondents states that, if he wants a really useful assistant, he has to train one himself, or procure one from the Continent, which, while conveying a compliment to the foreigner, rather tells against our correspondent's fellow-photographers in this country, and indirectly supports several of our original contentions.

On the whole, while regretting that several of our correspondents should have hastily misinterpreted some of our remarks, we are happy to have elicited a series of useful and instructive letters upon a subject which appears, as we surmised, to be of vital interest to professional photographers. It is a happy augury that those who have taken the strongest objection to our remarks have no reason to be dissatisfied with their share of success, and are, we are pleased to observe, in little need of our advice. Behind them, however, is a far larger class of photographers, for whom our remarks had special reference, for whose behoof and warning they were written, and to whom we commend a study of them, in the hope and belief that they, and professional photography generally, will be thereby ultimately benefited.

THE STANNOTYPE PROCESS FOR LANTERN SLIDES.

The stannotype process, when it was first introduced, was generally looked upon as a formidable rival to Woodburytype, though, as time proved, it did not commercially meet with the success that was anticipated for it. The process formed the subject of a patent, and that was said in some quarters to be the reason why it was received with so little favour. But this is a question we shall not discuss here. The process is really a good one, and for it the inventor, the late Mr. W. B. Woodbury, was awarded the progress medal of the Photographic

Society of Great Britain. Like the Woodburytype, it is equally as applicable for the production of transparencies as it is for paper prints; indeed, all that can be done by one process can be equally as well accomplished with the other, and all are familiar with the great excellence of Woodburytype lantern slides.

Both processes are by the same inventor, and are the same in principle, though they differ somewhat in practice. The Woodburytype may be termed a professional, while the Stannotype may be classed more as an amateur process, inasmuch as the former requires a somewhat costly plant for its working, while for the other nothing more is requisite, particularly for lantern slides than is to be found in the "den" of every amateur. In some respects stannotype has an advantage over Woodburytype, because for the latter process a vigorous negative is essential. With stannotype a tolerably weak negative may be utilised.

In the Woodburytype process the gelatine relief is produced direct from the negative, and, in order to obtain the necessary relief, that must possess a certain degree of vigour. From this relief the printing matrix is made by forcing it into the surface of a thick sheet of lead by hydraulic pressure, the pressure required being from four to five tons per square inch of surface. The prints are obtained by pouring on this mould warm ink which consists of pigmented gelatine, then placing on that a piece of paper or a glass plate, and applying sufficient pressure to distribute and force out the superfluous ink. As soon as the gelatine has set, the impression, which is in reality a cast, is taken off, and, after being dried, is finished. In the stannotype process a gelatine relief forms the actual printing plate, thus dispensing with the hydraulic press, the printing operation being conducted, whether on paper or glass, in precisely the same manner as in the process just referred to. Here is a brief description of the stannotype process in practice.

As the gelatine plate forms the actual printing plate or mould, a little consideration will show that it must be made from a transparency instead of a negative; also that the transparency must be reversed as regards left and right. It matters not how this transparency is produced, so long as it is of a vigorous character. In the case of a reduction from a larger negative, it must, of course, be made in the camera. When it is to be the same size as the negative, it may be made by contact printing. If, however, a dry plate be used, the picture will have to be stripped from the glass to get the necessary reversal. The more general method is—and it was the one usually adopted by Mr. Woodbury—to produce the transparency by the carbon process, developing it on a glass plate, and afterwards intensifying it with permanganate of potash if requisite. In making the transparency, which on the whole is best done by the carbon process, it must be made with a clear margin or "safe edge," by masking, and the extreme high lights must be represented by absolute transparency as clear as the safe edge. In fact, this transparency, whether good or bad, is a counterpart of what the finished print will be.

The tissue for the relief is not, we believe, an article of commerce, though, if a demand were created for it, no doubt it would soon become one. However, its manufacture on a small scale involves no difficulty whatever. There are several methods of making it. Here is one of the most simple:—A glass plate, after being treated with French chalk, is coated with a rather thin enamel collodion, and allowed to dry. It is then placed on a levelling stand, and coated with warm bichromated gelatine. The following is a good formula:—

Nelson's amber gelatine	5 ounces.
Loaf sugar	$1\frac{1}{4}$ „
Glycerine	$\frac{1}{2}$ „
Ammonia	2 drams.
Water	1 pint.

With sufficient Indian ink to confer a slightly brown tint.

When the gelatine is dissolved, and shortly before using, from three-quarters to one ounce, according to the temperature, of powdered bichromate of potash, is added. Sufficient of this mixture is poured on the levelled plate to form a film, when dry, the thickness of a stout visiting card. This, for a 12×10 plate, will take about five ounces. The gelatine quickly sets, when the plate can be removed for drying. As, owing to its thickness, the film in the ordinary way would take a long time to dry, during which period the tissue would be getting more or less insoluble, the plate is placed over a tray of chloride of calcium, which considerably hastens the operation. When dry, the tissue is stripped off, and it is ready for printing.

Before printing, a second safe edge mask, narrower than the first, is fixed on the transparency so that a strip of clear glass is left between that and the picture. The tissue is placed on the transparency, collodion side downwards, and exposed to the light in an ordinary pressure frame. The exposure should be about three times that required for an ordinary carbon print, with tissue of equal sensitiveness. The development is conducted as follows:—Some glass plates are coated with a substratum of gelatine. One ounce of gelatine to a pint of water, with sufficient chrome alum added to render the film insoluble when dry; or, better still, a little bichromate of potash, enough to give it a pale yellow tint, the plates in this case being dried in full daylight. The exposed print is immersed, with one of the plates, in cold water, and when it it becomes slightly flaccid it is squeegeed on to the prepared glass. After resting for twenty minutes or so, the image is developed precisely as if it were a carbon print, except that a much longer time must be allowed for the operation, and considerably hotter water used. The development may extend from a couple of hours to twenty-four or longer. The usual plan is, after a good portion of the unaltered gelatine has been dissolved away, to put the plate in a grooved vessel of water, such as a tin washing trough, over a small gas flame or spirit lamp, and let it take care of itself, with occasional examinations. In the end an image will be obtained with a sufficiently high relief for the purpose.

When the developed relief has drained, until it has become surface dry, it is placed in methylated spirit for an hour or so, then taken out, and allowed to dry spontaneously. It is next coated with a thin solution of indiarubber in benzol—two or three grains to the ounce—drained, and dried. Then a thin and perfectly smooth sheet of tinfoil is laid upon it, and the whole passed several times between a pair of elastic rollers, which will cause the foil to adhere and take all the detail of the gelatine image. The domestic wringing machine will do perfectly well; but for small sizes, such as lantern slides, a soft rubber roller squeegee will answer perfectly. The relief is now ready for printing from. For transparencies on glass no press is necessary. All that has to be done is, after rubbing the surface of the tinfoil with a soft rag moistened with olive oil, to pour on the warmed gelatinous ink, press on the glass with a gentle pressure to squeeze out the superfluous ink, and

allow it to remain until the gelatine has set. It is then removed and allowed to dry spontaneously, when it is finished. Tinfoil is to be had coated with iron. Its surface is then as hard as the "steel facing" on an engraved copperplate; but, if only a few scores of impressions are wanted, the ordinary tinfoil of commerce will prove sufficiently durable. The printing, or rather moulding, ink is simply a strong solution of gelatine—say, sixty grains to the ounce of water—to which has been added any colouring matter that may be desired. Any colour can be employed, and the quantity of pigment added determines the density of the image; hence it can be regulated to suit the light of any lantern.

From the above brief description it will be seen that the stannotype process—and there is now no patent for it—offers no difficulties whatever to those who are familiar with carbon printing, which a large number of amateurs now are. A very comprehensive series of articles, giving full working details of the process, were given in our volume for 1884, which will be found of great service to those who may be inclined to essay the process, either for lantern slides or for paper prints.

The Photographic Society's Exhibition.—We understand that the number of pictures recently sent in to the Exhibition showed a considerable increase on those submitted last year. Having regard to certain events which have occurred in the history of the Society during the past few months, such a circumstance must be very gratifying to all those who are interested in its welfare. The Exhibition, which is to be inaugurated by the usual conversazione to-morrow (Saturday) evening, will be opened to the public on Monday next.

Hot Water and "Curled" Aristotypes.—In the course of a chatty discourse on American plates and printing processes before the London and Provincial Photographic Association, on Thursday week, Dr. Charles L. Mitchell, of Philadelphia, alluded to the fact that American workers of Aristotype paper—that is, collodio-chloride as distinct from the gelatine surface—remedy the tendency of the paper to curl in the solutions by treating it with boiling water. The hint should be of value to those experiencing a similar difficulty this side, always assuming, of course, that a collodion paper is in question. With gelatine paper such a remedy would be—well, unsuitable. By the way, Dr. Mitchell returned to America a week ago with, from what we gathered from him, the happiest impressions of his visit.

Cut Films in Professional Practice.—Although the value of cut films has long been established, more especially those of the smaller sizes, yet it is well that the endorsement of such a well-known practical man as Mr. William England should be put upon record. This veteran photographer, who has just returned from Switzerland, informs us that when he went abroad he took with him twenty-four dozen whole-plate and half-plate films, and, having developed them all, is in a position to say that he has not experienced a single failure directly or indirectly traceable to his having used films instead of glass, as formerly. His film holders are made with a slight curve, causing the films to assume a cylindrical bend towards the lens, and this enabled him to get marginal sharpness when employing a stop larger in size than would suffice if the film were impressed when in a flat position.

A Big Telescope.—Most of our readers will have come across one of the many accounts of the great telescope which is to be built for the projected Paris Exposition of 1900, and they have probably wondered what photographic results would probably be obtained from it. It is positively stated that the glass-works of St. Gobain have accepted the commission to make the objective, and that they will have it ready before 1900. So wonderful is the promised instrument that it is to bring the moon as near as a yard, or, at most, a metre! Now, to any one at all cognisant of optical matters, all this is simply nonsense, and even if we look upon the yard as a slip of the pen for mile the thing is practically impossible. With the great Lick telescope the moon may be brought within, apparently, about a hundred miles; under the most favourable conditions we could scarcely hope for an instrument ever to be made more than twice as powerful. Above all, the larger the instrument the more difficult to find an evening with suitable atmospheric conditions. A three-inch objective might be used almost any night, a three-foot but occasionally. Such a one as is now promised perhaps might be used once in a few years!

Daytime Seeing at the Lick Observatory.—Under the above heading a letter from the Lick Observatory, over the signature of Henry Crew, is printed in last week's *Nature*, giving the results of some very interesting experiments in the use of the telescope in daytime. Using the thirty-six-inch instrument, with a Rowland grating, he found it impossible to get any definition from the solar prominences. Then, working in the early morning, he tried the twelve and the six-inch equatorials. Result:—After half a dozen mornings' observations, *nil* with the thirty-six inch; general features considerably more distinct with the twelve-inch; but the fine, delicate tracings of the various parts of the prominence could only be seen with the six-inch. *En passant*, it may be noted that Mr. Crew finds the definition of the objective interfered with during daytime by the heated currents of air produced by the intensely hot sides of the cañons brought about by the sun's rays. By the way, there seems to be something very much amiss in the management of that institution, for within twelve months three eminent workers have seceded from its staff.

CONVENTION JOTTINGS.—IX.*

A Run through Some of the Scotch Studios.

JOHN FERGUS, Blackdales, Largs.

WE took train for Wemyss Bay, where Mr. John Fergus met us, and drove us down to his place at Largs—a charming drive along the fringe of the sea, with the Cumbrae Islands lying out to the right, and Fairlie away in the distance beyond Largs, with the yachts and boats dancing about in a silvery sea, bringing to mind that day we spent at the Glasgow Convention, when in these very waters so many of us went yacht shooting—a day to be remembered—when hundreds of plates were exposed, and many beautiful pictures were taken. We reached Largs, that village in a quiet corner of the Clyde, where Mr. Fergus has for years drawn thousands of people that have visited the place only for his pictures, his *clientèle* embracing all sorts and conditions of men, and women too, and from all parts of the world.

As we drove along, Mr. Fergus pointed out the little place where he made his first venture, and also the little well where in those early days he used to wash his prints.

And then we were shown the next studio that he occupied, one of larger growth, and more pretentious, bespeaking the steady growth of business in the little town, and from the front street we drive away up past the railway station, and on to the Fairlie road. At the foot of the hill, and surrounded with trees, we came upon Blackdales, the name of the estate on which the present studio is built. No need for Mr. Fergus to be in a public place now for business, for the visitors to his studio come with intent, as there is no such thing as chance business here.

The showroom is built along the edge of the roadway, being specially built for the purpose; it takes the form of a long picture gallery, and it is lighted from the roof. On entering this room, we find it furnished with settees and other easy lounging-chairs, a turkey carpet on the centre of the floor, the polished wood floor all round being left uncovered. This room is filled with the best examples of Mr. Fergus's work from carte up to life size, large work in platinum, bromides, and carbon being very prominent. The

* Concluded.

room is suitably arranged with stands and easels for the better display of these artistic productions.

Leaving this room, we pass through a corridor that leads us up some steps on the right to the main corridor, which stretches from end to end of the building; all along either side is arranged with draperies, statues, plants, and paintings, producing the most artistic of effects, as the receding objects lessen in the distance and the green leaves glisten in the sunshine outside.

The dressing-rooms enter from this gallery, the same rooms on the opposite side being in communication with the glass-house in which the sitter is to be taken.

The studio (or rather studios) is a long range of glass-houses, lofty and built dome shape, and so subdivided inside that it forms five or six complete studios, having partitions between the partitions themselves forming backgrounds and other effects for picture-making.

The first of these studios is furnished and arranged for taking those large "at home" pictures, of which Mr. Fergus has made a special feature, and which, in his hands, have proved such a success. All the furniture and fittings in this studio have been carefully thought out and arranged so as to represent the home drawing-room. Family groups can be, by this means, taken with all the semblance of being at home, giving an ease of pose and variety of position, which is a great advantage, pictorially, over the usual stereotyped studio group.

The other studios are each for certain classes of work. Mr. Fergus is a great believer in reflected light, and many of the finest effects that are to be seen in his pictures are produced by hand and other reflectors.

There are dark rooms in connexion with the studios, but the principal dark room is under the studio, with a convenient stair down. This is a large cool apartment, and must be pleasant to work in, being fitted with every appliance.

Here we saw a very ingenious contrivance in the way of developing rockers, the invention of Mr. Alexander, Mr. Fergus's manager.

This table is moved by an eccentric arm joined to a small water wheel, and has a balancing weight arranged at the other end of this table to the arm; ten or twelve trays can be arranged upon it, and when the water wheel is set a-going the liquid in the trays is kept in constant motion till the negatives are fully developed.

Mr. Alexander has had this machine in use for long before any of the advertised "rockers" were on the market.

Being pressed for room, Mr. Fergus has just had two new studios erected; they are also dome top; they enter from the small corridor that leads out of the showrooms. These two studios were scarcely finished when we were there, but have every chance of being in full swing now.

Some years ago Mr. Fergus opened a business in cameras, and as the season there was the quiet time at Largs he saw his way to work both, and he did a considerable trade, and was gathering around him a connexion of the highest order. The prosecution of this profitable speculation had to be abandoned last season, owing to Mr. Fergus turning seriously ill just when about to start, and the place had to remain closed. He may open it again next season.

We were glad to see, however, that Mr. Fergus had regained his usual good health. After spending a very pleasant and enjoyable day, in the most charming of places, under the charge of the most kindly and courteous of hosts, we left well pleased with our visit.

A. Swan Watson (View Park Studios, Edinburgh).

On our return to Edinburgh on our way south, we paid a visit to the View Park Art Studios, which were built out at Bruntsfield Links by Mr. A. Swan Watson, from Marshall Wane's. Mr. Watson, previous to going into business for himself, had made his mark in the profession in the production of cloud pictures and transparencies. The circular stand of transparencies that was on view at the Edinburgh International Photographic Exhibition, which created so much attention, was the work of Mr. Watson; and the two frames of portraits with new and unusual lighting shown at the Glasgow Exhibition—that were so much commented on and admired by many—were also his work.

View Park Studios is all built on one floor, and, having eighteen apartments, in all, covers a considerable piece of ground.

The reception-room is at the entrance-way, and is in the form of a gallery, forty feet long by twenty-four feet wide. It is lighted from the top, the light being well diffused through fine ground glass, giving a soft and subdued light to the whole room, freeing the pictures from glare and direct sunshine, which is so objectionable in rooms too brightly illuminated. All classes of work are here shown, from cabinets up to forty inches, in silver, carbon, and platinotype, the display showing considerable artistic arrangement.

Leaving the reception-room, we enter a corridor, wide and well lighted, ninety feet long, and decorated with plants. There are some twelve windows in this passage-way, and each of these is fitted with Mr. Watson's beautiful transparencies of cloud pictures, landscapes, seascapes, and portraits, which renders it quite an attractive spot to linger in a while. On the left-hand side of this corridor are situated the dressing-rooms and studios.

The first studio is forty feet long by twenty wide, with a steep ground-glass roof. Mr. Watson says that it is easily worked, as, having the light under control and very rapid, the largest pictures, under ordinary circumstances, do not take more than from five to six seconds' exposure. The fact that there are no houses or other obstructions, and nothing but clear sky all around, is the reason Mr. Watson assigns for the quick action in his studio. He uses the quickest plates manufactured.

The second studio is divided from this by a dark room, but so constructed as to make one large studio when required—which is pretty often—for his group pictures, a class of work that Mr. Watson makes a special feature of. The first studio is used for the usual portrait work, and the second one for all kinds of exterior effects.

There is still another studio behind, which, we remember well, Mr. Shaw had fitted up for boat pictures—with boat, and sail, and real water, and imitation rocks, &c.; but in Mr. Watson's business the space was too valuable to be set aside for this one purpose; besides, he can get the same class of picture in his exterior studio when desired.

The next room we come to is specially for the production of platinum pictures, and close to this is the silver-printing department. Then come we to the rolling, burnishing, and finishing.

Outside there is garden ground, where horses and other equestrian pictures are taken, backgrounds and other accessories being arranged for this class of work.

A very complete place, in a district as quiet and open as if away in the country, and that within a two-mile car ride from the centre of the city, makes it a business place to be envied.

A STANDARD DEVELOPER.

As you have referred to our researches in your article upon a standard developer, we should like, with your permission, to make a few remarks upon the subject.

We are entirely in accord with you that it is the exposure, and not the development, which rules the result due to the action of light on the sensitive plate. We also agree with you that one film may take five, while another may require ten, minutes' development in order to reach the same ultimate density. We, however, take exception to your view that similar isolated densities, resulting from similar exposures, would be a proof of equality of sensitiveness. This view would truly apply in the case of a series of gradations, but not in the case of single densities. We hope, as we proceed, to make this clear.

You say that the question has been raised whether, in making sensitometer trials, a fixed period of development should be adopted, or whether development should be allowed to act, so as "to get out as much as possible" from the exposure. You then state that, in your opinion, the latter is the better plan; and you are apparently under the impression that we participate in this opinion. This is not, by any means, the case, for it is a most important feature in our method of speed determination that the influence of time of development is altogether eliminated.

We have shown that while, with time of development, the densities do actually alter, their ratios remain constant; and as it is the relationship existing between a series of densities, and not the densities themselves, which determine the speed, time of development plays no part in the determination. Practically, it is well, on the one hand, to avoid very short, and, on the other hand, very long development. On account of irregular action, probably due to the physical resist-

ance of gelatine to penetration by the developer, very short development is undesirable, and very long development is liable to produce extreme densities, which present great difficulty in measuring. Hence we find it best, in practice, to reach a development factor of from 1·0 to 1·5; but the time required to do this varies, of course, with the plate, with the developer, and with the temperature. From a purely theoretical point of view, time of development has no influence whatever upon the result.

It would not be at all a safe conclusion to arrive at that if two films yielded the same ultimate density with the same exposure, even though different times of development might be required in the two cases to reach this density, the two films would be equally sensitive. The comparison of single densities can never be any criterion as to speed, nor would it be safe to conclude that a series of gradations produced by similar exposures on two different films would be alike, because one particular exposure led to similar isolated densities in the two cases.

A striking illustration of what we say has just occurred in the case of two speed determinations which we made a few days ago. The following table gives the density readings:—

Exposures C.M.S.	Plate A.	Plate B.
0·625	0·130	0·080
1·25	0·330	0·285
2·5	0·600	0·600
5	0·940	0·945
10	1·190	1·220
20	1·395	1·465
40	1·520	1·620
80	1·605	1·750

The two plates were simultaneously exposed for eight different periods, varying from 0·625 C.M.S. to 80 C.M.S. The development factor is the same in both cases, so that the development was continued up to and stopped at precisely the same point in each plate. It will be seen from these figures that no estimate of the relative speed of these plates could possibly be arrived at by comparing any corresponding pair of densities resulting from the same exposure. Take the two densities due to exposure 0·625 C.M.S.; A is greater than B, and hence the inference would be that A would be the quicker plate, because the light did more work with the same exposure. Next, take the two densities due to exposure 80 C.M.S.; B is greater than A, and B would now, for the same reason, appear to be the quicker plate. Lastly, take the densities due to exposure 2·5 C.M.S.; in this case they are equal, and the inference would be that the plates are of equal sensitiveness. So that, from this illustration, it will be seen that, from a mere comparison of corresponding single densities, either of these plates might be considered quicker than the other, or they might be considered as of equal speed.

As a matter of fact, the two plates are of almost equal rapidity, but this fact is ascertained by the relationship existing between the densities of each plate, individually considered, and has nothing to do with the relative values of the corresponding densities of the two plates. The difference in the gradations of the two plates is simply due to a difference in the amount of silver salt present on the plates, B being the more richly coated plate and having, in consequence, the greater capacity for truthful representation. Had the time of development been curtailed or prolonged in the case of either or both plates, it would have made no difference to the determination of the speed; the densities would, in these cases, have been generally increased or diminished, but their ratios would have remained unaltered.

The time of development required to reach a given development factor varies so widely in the case of different plates that no method of speed determination can ever be satisfactory in which the time of development has any influence upon the result.

With respect to your remarks upon the choice of a standard developer, we should like to say a few words. We are as fully convinced as we were when we wrote our original paper that, for the purpose of speed determination, and for scientific investigation generally, there is no developer comparable with ferrous oxalate. That developer must be the best, in our opinion, which has the least tendency to reduce silver salts which have not been submitted to the action of light, and, as far as our experience goes, ferrous oxalate bears the palm in this respect. We therefore strenuously urge its use for the purpose of speed determination by our method. You point out, as an objection to this developer, the difficulty of securing solutions of a uniform degree of saturation, but we have not found that any variation which takes place in practice has any appreciable influence upon the result. Any variation in this strength, within, at any rate, extremely wide limits, would merely hasten or retard the time of development; and this, as we have shown, would have no influence upon the speed, as determined by our method. The fact that time of development may be disregarded as a factor in the consideration of speed determination, renders fluctuations in the strength of the developer of much less importance than your article would indicate, and, in consequence, greatly facilitates the choice of a standard developer.

For ordinary photography, we are quite prepared to admit the claims of pyrogallol, and frequently resort to its use ourselves. It has, however, in common with all alkaline developers, a disagreeable tendency to attack silver salts which have not been exposed to the light, and this renders it inferior to ferrous oxalate for strictly scientific work. Otherwise, it is cleanly in use, economical, and convenient. Our objections to pyrogallol for scientific work apply, of course, most strongly when used in conjunction with ammonia.

With respect to those developers more recently introduced, we do not think they will ever become formidable rivals to ferrous oxalate and pyrogallol for general work. When we first published our investigations we had only had experience of hydroquinone and eikonogen, neither of which did we find up to them, to materially affect the speed of plates as determined by ferrous oxalate or pyrogallol. We pointed out, however, that there was a theoretical possibility of a plate being fast to one developer and slow to another.

We have recently made some investigations on development with rodinal, and the results so far indicate that this developer has the property of increasing the speed of some plates in a very marked degree. We say "some" plates advisedly, for, unfortunately, it does not apply to all; the speed of some plates is not increased at all under the influence of rodinal, while, in the case of others, it is materially augmented. As an illustration of this, we tested a plate recently, the speed of which, as determined by pyrogallol, was forty-seven, and, by rodinal, 155. To rodinal the plate was about three and a half times as fast as to pyrogallol, and this was fully confirmed by camera tests made afterwards. It appears to us that rodinal may prove of great value for "instantaneous" work, but plates would have to be selected for the purpose which are amenable to development by rodinal in this enhanced degree. As it is, it is impossible to state any general relation between the speed of a plate as developed by ferrous oxalate and by rodinal; the speed would require to be determined for each. The fact that rodinal, compared with ferrous oxalate or pyrogallol, affects different plates in different degrees can only be accounted for on the ground that plates are differently constituted with regard to the gelatine and halogen salts they contain, and this opens up a wide field for future inquiry.

F. Hurter.
V. C. Driffield.

DECORATIONS AND FITTINGS.

Perhaps nothing impresses prospective customers favourably or otherwise during a visit to the photographer's more than the appearance of the reception-rooms and studio. It is therefore to the interest of the business man to exercise every care that such impressions are pleasant ones. In this matter there is unlimited scope for the exercise of individual taste, very widely divergent schemes producing equally satisfactory effects. Where there is the advantage of a *lobby* opening directly into a thoroughfare it should be filled, but without crowding, with good and effective pictures, displaying to advantage the different kinds of work undertaken, all perfect copies, artistically arranged, and *frequently changed*. Something new will always attract the public, and to arrest the attention is the first step to securing the customer. The less ornament about this lobby the better: plain and good fittings are always to be preferred. There is a certain section of the public particularly active in damaging and defacing anything that at all lends itself to be maltreated, and light ornamental work within reach of mischievous fingers is sure to suffer, therefore the plainer and more solid the fittings the better, even at the sacrifice of prettiness. Next comes the staircase. For my own part I do not think it is a good plan to hang pictures on staircases, but the walls should be nicely decorated. Any special notices may be placed there perhaps with advantage, in such a position that they can be easily read as the customer enters or departs, at the same time avoiding anything of an attractive nature calculated to induce prolonged examination. The covering of the stairs depends very much on the class of customers, and beauty in this instance may give place to utility without infringing on good taste. The reception room is really the first apartment that requires special attention to its adornment, and no pains-

should be spared to make it as attractive as possible. In this room customers have to wait until the operator is at liberty to attend to them, and during this time they should be kept interested and in a good temper. Here, undoubtedly, is the best opportunity for the display of specimens, and shows of what stuff the reception-room lady is made by the exercise of her ability in securing good orders. A judicious selection of work is, therefore, a most important matter. The more varied and attractive it is the better is the chance of profitable business. If a fairly brisk trade is done, the specimens themselves or their position should be daily altered, but on no account should inferior work be exhibited. The public is insatiable in its desire for novelty, and, as in most houses the number of really good and attractive specimens is limited, the mere alteration of their position will in some degree supply the want. We must not look to quantity alone to secure customers, for a great crowd of fairly good portraits will have less beneficial effect on trade than a much less number chosen with judicious reference to their interest and quality. There are but few clients who will struggle through frame after frame containing hundreds of *cartes-de-visite* or cabinets. There is too much monotony about the proceeding, however good they may be, and their examination only evolves a sort of mental confusion instead of fixing in the mind some artistic and pretty pose that will induce a desire to possess a similar picture.

The usual effect of crowded frames of small works is that of obtaining a rapid survey in order to ascertain if there is any one amongst them known to the examiners, and if no one is discovered there is no further interest in the matter, when if a few of the same pictures were more isolated, would each command a more careful and critical examination, and probably have a much better business effect. Some of every kind of work undertaken by the firm should be represented, plainly but richly mounted and framed; in fact, the mounting and framing is most important if pictures are to be shown to the best advantage.

With respect to *cartes-de-visite* and similar small pictures, they are better enclosed in albums or folding cases where only one or two can be seen at a time, than arranged row above row in large frames like tailor's patterns, a plan so universally adopted. When the accommodation is sufficient, coloured work is best kept together, and not indiscriminately mixed with plain photographs, which invariably lose by the contrast. Enlargements should be hung or placed on easels so that they can be viewed at a *sufficient distance*, they *never* look to advantage from a near point of sight. A portfolio or a stand containing choice mounted platinotypes is an acquisition. Carbon and bromide prints are soon spoiled by friction when shown in this manner, but platinotypes will stand a good deal of hard wear before becoming defective. Any prints on gelatine surfaces are easily damaged, even albumen or silver prints get dull and scratched, and although tolerably hard soon lose their pristine freshness by rubbing much together. It is an excellent plan to protect each print with a piece of tissue paper fastened to one edge of the mount and covering the print.

It is usually found that when a picture, or anything else for that matter, is treated with special care, as is a valuable work, it will be handled much more carefully than if it was exhibited as only one of a large number deserving only ordinary attention. Its worth is undoubtedly enhanced in the eyes of others if the owner exhibits marked interest in its preservation independent of its intrinsic value.

(*To be concluded.*)

ON THINGS IN GENERAL.

Page 559 of this Journal contains two letters bearing on very important practical matters, the first being that over the signature of "Film Fiend," a writer who raises a question of the very highest importance with regard to the permanency or otherwise of gelatine dry-plate negatives treated with alum. Nineteen out of every twenty photographers who employ this chemical appear to be wholly ignorant of its true function or its possible after-effects. Most of them would say "No" to this statement; they know its use and properties quite well—"hypo is injurious left in print or negative, alum destroys the last trace of it; what more can be desired?" A half truth, of a very misleading nature! It is true alum does decompose hypo, but it does not "destroy" it; that would be an absurd supposition. It merely changes it into other chemical compounds, presumably less injurious than "hypo,"—a presumption not proved—but it does not get rid of the silver dissolved in the hypo, and the cause of much that is defective and fugacious in photographic prints is to be sought in the metamorphosis of that argentous residuum. As to the use of alum with negatives, it is commonly suggested that it removes the yellowness from pyro-developed plates, a function which is far better performed by a weak acid, and equally well, and far more safely, by acidifying the fixing solution with an acid sulphite, to which has been added, preferably, a little neutral sulphite. (By the bye, it is not generally known that the late Mr. H. Berkeley—who gave to an unheeding photographic community, and without charge, the knowledge of the use of sulphite—took out a patent for the use of acid sulphite in the fixing bath. As to the validity of the patent, if it had been continued, I offer no opinion). The only use, therefore, that alum can possess is as a hardener of the gelatine, and a frill preventer. It is useless to add it after fixing and complete washing; for, if the evil was to become manifest, it would have worked its fell way by this time. To use it soon after fixing constitutes the grave error I am lifting up my literary voice against. To use it before fixing will entail equal ill effects, unless a very thorough washing be given. We can now arrive at the point, and at Mr. "Film Fiend's" trouble. Alum or hypo is used first, a "rinse" is given, and then the other salt of the twain is put into use. I should like to remind every one who carries out such a course of treatment that a rinse is an absurdity, as applied to a gelatine film; a very thorough washing, extending over a considerable period of time, is necessary for the removal of any chemical from the substance of even a very thin layer of gelatine; the stream of water does not dash through the gelatine and reach the glass it lies upon; all that the stream of water does is to supply a continuous quantity of liquid, into which the salts pass by diffusion out of the gelatine. Hence, if any one give a slight time only, even in a strong current of water, to the removal of a chemical from the gelatine film, he will not succeed; his plate, when dry, will contain a residue of that chemical to work what evil it may. A plate rinsed from alum and placed in hypo will contain within itself the germs of future danger, and it will be remarkable if there be not found some amount of yellowing, if not worse, in any and every negative so treated after, say, a year's storage.

The second letter I allude to refers to the exceedingly simple piece of apparatus, the camera-back turn-button—those terribly annoying necessities with regard to which one feels that it is difficult to know whether they are more detrimental to the nails and digital extremities or to the mental equilibrium of a good man. Who is there that has not experienced the dead-lock—literally "lock"—that they present, always when most haste is needed, so that nothing but a hammer or pair of strong pincers will apparently shift them, and just when it is impossible to take the slide out of the dark room? Who that has not had the mortifying experience of seeing a button, that has worked itself loose without being detected, give way, and allow the plate to slip out just when an unusually successful exposure has been made? An amount of ingenuity, sufficient to build a score of Eiffel Towers, has been expended over every part of a camera, except this insignificant little adjunct. Surely, now this grievance has been aired *coram populo*, a little mental sleight will be expended in provising a remedy. Let us hope it may.

Miss Catharine Weed Barnes has given us some valuable practical remarks on American photographers and their apparatus. She may be right about the pull-out, instead of fixed, shutters to the dark slides; but I must say the only time I ever used such backs (true they were English-made, but of excellent quality) they played me a scurvy trick, and spoiled several plates, through the light gaining entrance when I inserted the shutter. It was a windy day, I admit, and the "black cloth" did not cover the camera as I should have liked: but, then, one ought not to be dependent upon a dark cloth to protect one's slides against light. Possibly they—the apparatus-makers—manage these things better in America.

Every one who reads the correspondence columns of the Journal will have been deeply interested in the discussion about assistants and their all-roundness. Mr. Wilson puts the matter in the proper light. Mr. J. Pike proves too much. He says an "older person," in two years' time, can learn much more than "to operate, retouch a little, print in various methods, enlarge, and copy." Most true; but what would be the value of his services in any one of those departments after the above varied experience? Just about what a porter could get, certainly not more. Any practical photographer knows that it

is absurd to suppose that a man, with so brief an experience, could do really good work in any one department. A first-class printer alone could not be made in two years, nor a retoucher who could earn thirty shillings a week; and as to operating, well, the thought of the possibility raises a smile. As to Mr. Pike's friend who, in two years' time, became expert in operating, printing in all known printing processes, enlarging, photo-mechanical and microscopic work, able to retouch and make slides, yet who found he could not obtain a salary approaching the hundred and fifty pounds a year he had previously obtained, I ask, is it possible, if Mr. Pike's letter is not a huge joke, that the reason of his failure is not seen? All I can say is that, if such a photographic Admirable Crichton applied to me, in the event of my wanting a capable operator or printer in any one known process, or retoucher, I would not take the trouble to read his testimonials! FREE LANCE.

DR. H. W. VOGEL ON THE DECAY OF PROFESSIONAL PHOTOGRAPHY.

IN THE BRITISH JOURNAL OF PHOTOGRAPHY of August 5 I find an article entitled, "The Decay of Professional Photography," says Dr. Vogel, in *Anthony's Bulletin*. The contents of this article are almost synonymous with a letter received by me from Herr Paar. The evil seems, therefore, to be a general one, and deserves the greatest attention. Herr Paar writes:—

"The relation of any class of society to the book trade is the surest educational test." This is the expression of a man of celebrity. Education is, indeed, transposed knowledge, and knowledge has to be acquired, must be learned. The book trade now is the mediator between the majority needing instruction and the single members of society having instructive capacity, whose liberated products of intellect are offered to the former. Teaching and learning were in former times the privilege of a few; to-day they are the common property of everybody, and still how few make use of the latter! Without the book trade, no education, no progressive culture. The conclusion is, that the more intimate the intercourse of a certain class of people is with the book trade, the higher must be the degree of education. The contrary conclusion would consequently be that, the more deficient the intercourse of another class is with the book trade, the more deficient must be the educational degree of this same class, and that it is high time for this part of society to remove the evil. What class of society is in this condition? One of the most prominent merchants in the book trade gives us the necessary information. Listen!

"The professional photographic circles are not very generous buyers of photographic literature, and if it was not for the amateur photographers it would be impossible to do business in that line."

This is a judgment, just as annihilating as short, which has been passed by that gentleman during a correspondence with me, and his professional standing is sufficient guarantee for the correctness of his assertion. Unfortunately, it is not very flattering to belong to a class of society about which sentence is pronounced in such a way. The deficient demand for photo-literary products is by no means a final proof of the deficiency of a requirement for intellectual products. Well, there is hope, then; let us stick to it like the drowning person to a straw; may it never prove to be treacherous. I, for my part, will not put my foot in the bottom of such a frail craft.

What, now, is the cause of this evil? That it exists, this prime defect of our elementary education, we cannot help. But that it remains in evidence and will never make way, even in later years, that is our fault, and the reason is to be found in everything. Professional papers and institutions, unions of employers and *employés*, rival in the endeavour to finish the roof of a building whose foundation is wanting, and some even take pains to carry away some of the building stone, collected without selfishness by the more meritorious. Therefore, you gentlemen of the pen, look for the good where you can find it, and help to distribute it; the bad may pass away without your help. Try your best to induce people to read and learn, but do not attempt to extinguish it. Knowledge of the situation will be a natural result of reading and learning. An energetic perseverance is, of course, a necessary requirement. Take, for instance, the province of Silesia, and here is an inevitable fact, that eighty per cent. of the subscribers of a photographic paper lay the same aside unread, while of the other twenty per cent. one-half read nothing but the advertisements. The proportion would probably be a more favourable one if I had found better opportunity for collecting information in amateur circles. I was restricted mostly to professional photographers.

Again I ask, What is the reason? Simply because our photographers do not care about learning anything to increase their knowledge. They abuse the amateurs, whose number increases daily, and do not consider that, if they gain superiority, the reason is only in their greater education and intelligence. Only with education and intelligence can they meet the increasing competition of the amateurs.

At a meeting held some time ago about photography and printing processes, there was only one photographer in an audience of 500, and he said, "Yes! yes! my colleagues know already too much." The same has taken place at meetings in other cities. Only in the United States I had in that respect good success, and had always a full house, in spite of my bad English; and I may pronounce with safety that the acquisition of intelligence and learning is there more popular than in the old world.

CONTINENTAL NOTES AND NEWS.

The Brussels Congress, 1891.—We have received the report of the International Congress of Photography which was held at Brussels in the month of August last year. The volume extends to 150 pages, and gives a detailed account of the proceedings of the Congress, with the chief points of which our readers have already been made acquainted.

A Non-alcoholic Varnish.—According to the *Archiv*, the following varnish without alcohol answers well for prints, negatives, &c.:—

Water	320 parts.
White gum lac	32 „
Borax	8 „
Carbonate of soda	2 „
Glycerine	2 „

The borax and the soda are dissolved in 160 parts of the water, the gum then being added. After filtration, the glycerine in the remaining 160 parts of water are added. The deposit which forms after a time is removed by filtration, and the varnish is ready for use.

Rodinal.—In examining the properties of this developer, Dr. Andresen recommends that development should be commenced with a weak solution, 1·30, and, if necessary, followed by a solution composed as follows:—

Rodinal	30 c.c.
Potassium bromide	10 grammes.
Water	30 c.c.

Rodinal is not affected by fluctuations of temperature. The negatives are said to appear to lose density in the fixing bath, so that development is recommended to be carried to a greater length than usual.

Blackening Film-carriers.—The following formula is recommended for blackening those parts of film-carriers which are made of zinc, and require to be so treated:—

Nitrate of zinc	2 parts by weight.
Chloride of copper	3 „
Hydrochloric acid	8 „
Distilled water	64 „

The hydrochloric acid is added after the salts have been dissolved, and the zinc is plunged into the solution after it has been cleaned with sand.

A Modified Platinum Process.—M. Ganichot, in *Science en Famille*, claims to have secured excellent results with a paper prepared in this manner: To 1000 parts of distilled water he adds 125 grammes of perchloride of iron, and, after filtration, adds liquor ammoniæ until precipitation of the hydrated ferric oxide ceases, to which, after it has been washed, is added a hot solution consisting of 50 grammes of oxalic acid in 150 c.c. of water. In order to assure the neutrality of this solution, a little of the ferric oxide is left undissolved. After filtration, 2·50 grammes of chloro-platinite of soda are added, and the solution made up to a volume of 250 c.c. with distilled water. The paper is coated, dried, and printed in the usual way, and the image developed in a bath of—

Oxalic acid	25 grammes.
Chloro-platinite of soda	2·50 „
Water	250 c.c.

The presence of the platinum in the developer as well as in the paper is explained by the circumstance that the latter is insufficient to form an image. The process is said to give excellent detail and freedom from excessive contrasts, and, by the employment of chloro-platinite of soda, the paper is stated to be impervious to the effects of damp.

Toning after Fixing.—Captain Pizzighelli is responsible for the following formula for toning after fixing. The solution is said to give blue-black tones, and to keep indefinitely.

Ammonium sulpho-cyanide	30 grammes.
Gold chloride	3 „
Caustic potash	3 „
Water	100 grammes.

Hypo "Cartridges" and Developer "Pastils."—At the Vienna Society a few weeks back, samples of hypo cartridges were shown, each containing sufficient fixing agent to make 200 c.c. of solution at a strength of 1:4. A refinement of the same idea has been invented by M. Loeblein, of Carlsruhe—compressed developer pastils to wit. Sugar paste is the vehicle, and at one side it holds the alkali and at the other the reducing agent. What next?

Honours for Dr. Eder.—By an Imperial decree, Dr. J. M. Eder, the famous director of the Vienna High School of Photography, has been nominated Professor Extraordinary of Photo-chemistry at the Polytechnic School of the same town.

Enamelling Without Collodion or Gelatine.—The *Progrès Photographique* says that, for this purpose, equal parts of oxgall and alcohol should be let stand for three days, when it should be filtered for use. A glass plate is then coated with the solution, and the print laid upon it in close contact. After drying, which takes about an hour, a sheet of paper is pasted on the back of the print, the paper being then coated with a mixture of gum, dextrine, and a little glycerine. The whole being dry is removed from the plate, and applied with pressure to a mount previously wetted, in order to have the print mounted with a full gloss.

ASTRONOMICAL PHOTOGRAPHY.

[Hiawatha Camera Club, Minneapolis.]

The history of astronomical photography begins almost with that of photography itself. When the scientist, Arago, on August 19, 1839, announced to the French Academy of Sciences the great invention of Daguerre, he coupled with his announcement proposals to use the new art in obtaining pictures of the moon and of the solar spectrum. Arago characterised the invention as "a new instrument for the study of nature," the manifold uses of which must baffle, and would assuredly surpass, prediction. "In such matters as this," said he, "we must count most upon the unforeseen." And, indeed, the unforeseen has come to pass. Arago, with all his willingness to allow incalculable possibilities, would, doubtless, have been staggered by a forecast of the work now actually being done. The first attempts, however, at celestial photography proved disappointing failures. At Arago's suggestion, Daguerre exposed one of his sensitive plates to the rays of the moon, but with no result. In 1840, Dr. J. W. Draper, of New York, obtained a Daguerreotype of the moon, very imperfect, indeed, but prophetic of future success with proper appliances. He also, within a few years, obtained the first picture of the solar spectrum.

The First Star Photograph.

In 1850, the first star photograph, and also the first good photographs of the moon, were made by Professor G. P. Bond at Harvard College Observatory. The exhibition of one of these lunar photographs at the London Exhibition, in 1851, excited much interest, and was the means of stimulating Mr. Warren de la Rue, of London, to take up the study of this subject. He constructed for himself a thirteen-inch reflecting telescope, and, using the wet-collodion process, which had just then been discovered, obtained much better pictures of the moon than those by Bond.

In 1860 the first successful attempt was made to photograph the solar prominences or coloured flames around the edge of the sun at the time of a total eclipse, by Mr. De la Rue and Father Secchi. These photographs settled the question whether the prominences were appendages of the sun or of the moon, by showing the advance of the moon over them.

Rutherfurd's Refracting Telescope.

In 1864 a great step in advance was made by Mr. Rutherfurd, of New York, who constructed a refracting telescope with an object-glass of 11 in. aperture, designed expressly for photographic work. Let me say, in explanation here, that the rays of light which make the impression upon the sensitive plate are not the same as those which impress the retina of the eye. They are, in fact, most of them invisible to the eye. In the construction of the ordinary visual telescope the object-glass is so made as to bring to the same focus all the rays which are conspicuous to the eye, allowing all the others to go wild. The chemical rays of light, which are mostly invisible, do not come to focus at any one point, so that a perfect telescope for visual purposes will be a very poor photographic one; and *vice versâ*, if the chemical rays are brought to a single focus, the visual rays must go wild, so that a photographic telescope is worthless for visual purposes. Mr. Rutherfurd set the example of deliberately constructing a telescope totally unserviceable to the eye. With this telescope he obtained photographs of the sun, moon, and star clusters, some of which have not been surpassed until within the last two or three years. The reflecting telescope is not subject to the same difficulties in respect to focus as the refractor; all rays of light are brought to the same focus in the reflector. But there are other drawbacks to the use of this kind of telescope which have led most astronomers to prefer refractors. These difficulties have largely been overcome in the last few years, so that some of the best photographic work is now being done with large reflectors. The largest now in use is one with a 5 ft. mirror, recently completed by Mr. Common in England, and with which he is said to have obtained some excellent photographs of the planet Jupiter enlarged to one inch in diameter. Mr. Rutherfurd's work with his photographic refractor, and that of Dr. Henry Draper, of New York, with a 15 in. silver-on-glass reflector, at about the same time, may be regarded as the culmination of the art of celestial photography in its second or wet-collodion stage. The pictures, though excellent, did not compare with the views to be had through an ordinary 4 in. or 5 in. telescope. The plates were not sensitive enough for the very short exposures necessary to give sharp pictures of the moon and planets; on the other hand, the necessity of their being "wet" precluded the possibility of the long exposures necessary to impress upon the plate the images of very faint stars and nebulæ.

Little more was done on these lines for the next twenty years. The sun has, however, been photographed regularly at three or four different stations on the earth, so that we have an almost daily photographic record of the appearance of the sun since 1870.

Gelatine Plates and Astronomical Photography.

The introduction of the dry-plate process in 1871, and the subsequent rapid increase in the sensitiveness of the plates produced, have led to a wonderful development of the art of photography as applied to all branches of physical science, and especially to astronomy. The increased sensitiveness of the plates permits the exposures on bright objects to be shortened to such an extent that atmospheric disturbances produce but little effect in blurring the images—a difficulty which could not be avoided before. Photographs of the moon can be taken in less than one-half second, and the brighter planets in an almost equally short time. It is possible to photograph the sun in 1-100,000th of a second. Indeed, with the plates now on the market, it is difficult to make the exposure short enough. On the other hand, with dry plates the exposure on faint objects can be prolonged indefinitely with ever-increasing effect. Impressions on the sensitive plate are cumulative as well as permanent; those upon the living retina are neither. Impressions upon the human eye last but a small fraction of a second; after that length of time there is continual effacement and renewal. If this were not so, we could not so quickly turn our view from one object to another. Continual gazing at a faint star makes it no brighter to the sight. If we could lengthen the impression to one second, the sky would be almost ten ten times as bright as it is—*i.e.*, like the Milky Way, dimly luminous with minute stars. On the sensitive plate, however, the impression once made is permanent. The tiny ray of light from a distant star, which would make no impression on the eye, by its continued pulsations against the gelatine films, shakes apart one by one the molecules of the silver salts, until finally a perceptible image of the star is engraved. Thus it is that we are able to say we can photograph that which is invisible. It is possible too that there may be stars photographically bright which emit none of the visual rays, but whose light is wholly composed of the

invisible rays at the ultra-violet end of the spectrum. We have no evidence of such as yet; certainly no conspicuous ones have been found on the photographs.

Dr. Huggins, in England, was the first to perceive the singular adaptation of the dry plates to celestial research, and to use them in his experiments on photographing stellar spectra. His advice and example were followed a few years later by Draper and Gould in America and by Common and Jannsen in Europe. Other astronomers held aloof from the new methods, distrusting photography as a means of obtaining either perfect pictures or accurate measurements of the heavenly bodies.

Dr. Gill's Work.

In 1874 the transit of Venus was photographed at many places on the earth by expeditions sent out by the various Governments. The total failure of most of these photographs to give accurate measurements of the solar parallax added to the distrust in which photography was then held. The Americans, however, tried it again in 1882, and the results recently published of the measures of about 1600 photographs prove conclusively that photography can be relied upon as a means of accurate measurement. The decisive impulse toward the great astronomical undertaking of to-day came from the Cape of Good Hope. Dr. Gill, the Royal Astronomer, was one of the old school, devoted to accurate measurements with the meridian circle and the heliometer, little suspecting that in the camera an instrument was at hand more rapidly effective for the purposes of practical astronomy than the transit and heliometer. But in 1882 the splendid appearance of a great comet in the southern heavens challenged portrayal. Dr. Gill was not slow to make use of the means at hand, which were the two and a half inch camera and the experience of a local photographer, Mr. Aldis. Attaching the camera to the great equatorial, and using the latter as a guide to keep the image of the comet upon the same part of the sensitive plate, exposures of from half an hour to two hours and twenty minutes were made. The result was a series of pictures remarkable not only for the fidelity with which the comet was represented, but also for the accessory wealth of stars they displayed. The entire background was thickly strewn with them. Forty or fifty, down to the ninth magnitude, shone across the interposed film of the comet's tail. The exhibition of these photographs stirred up a great deal of interest in the subject of star-charting. They emphasised the advantages to be derived from the use of lenses of short focus and wide field, giving small bright images of tolerably extensive portions of sky. Experiments were begun in many quarters. Dr. Gill began at once a photographic survey of the southern heavens to supplement the work already done in the north by the old methods of Argelander. Professor Pickering, at Harvard College, and Espin and Roberts, of England, took up lines of photographic research, in which they have achieved eminent success.

The Brothers Henry at the Paris Observatory.

At the Paris Observatory at this time were two brothers, Paul and Prosper Henry by name, working together, charting by the old methods the faint stars along the ecliptic, with the purpose of discovering asteroids, or small planets. In ten years they had constructed sixteen maps of the seventy-two required. At the place where the ecliptic crosses the Milky Way an almost insuperable difficulty met them. The stars were so numerous that it was almost impossible to chart them by eye and hand. A glance at Dr. Gill's comet picture, with its starry background, suggested the way out of their difficulty; and at once they determined to give up the old method of charting by the eye and hand, and have recourse to photography. They set about the construction of a telescope on a novel plan—a twin telescope having two objectives, one adapted for chemical, the other for visual rays, enclosed in a single rectangular tube. The photographic objective is of thirteen inches aperture and eleven feet focus, its curves being computed so as to enable it to take in a wide area of the sky without sensible deformation of the images. The observer looks through the visual portion of the telescope at one of the brighter stars in the field of view, and keeps it constantly at the intersection of a pair of cross-threads, correcting by means of adjusting screws any irregularity of the movement of the driving clock. With this apparatus, during 1885 and 1886, many photographs were taken, surpassing in excellence anything ever seen before. Stars and nebulæ never seen were depicted on the plates. On one of them, covering an area of about four square degrees in the constellation of Cygnus, where 170 stars had previously been identified, some 5000 were clearly imprinted. In the familiar group of the Pleiades, where the best map before made, the result of many years' labour, contained 671 stars, photographs taken by the Henrys supply the material for charting 1421 stars, with a precision never reached by visual observations.

The Photographic Chart of the Heavens.

The significance of these results could not be mistaken. They pointed to a great task, no less than a complete photographic chart of the whole heavens. Dr. Gill proposed, in 1886, an international congress of astronomers to consider the question. The congress met in Paris in April, 1887, fifty-five delegates of fifteen different nationalities. They agreed to undertake the task, and appointed committees to consider best methods of work and of preservation of plates, &c., while the instruments were being constructed.

At a meeting of the permanent committee last year it was reported that seventeen observatories were ready to co-operate in the work; all the instruments had been finished, and most of them had already taken experimental photographs. The sky had been divided into zones, and these zones apportioned to the different observatories in such a manner as to make the conditions of observing as nearly alike as possible. The telescopes are all essentially alike, the plates are to be of the same size, made by the same formula, and developed in the same manner.

We have thus already begun the stupendous task of photographing on a large scale, and in a short time, the whole heavens. It will require over 10,000 plates to cover the sky, and each is to be done in duplicate. Allowing for failures, something over 25,000 plates will have to be exposed. The exposure is to be one hour for each. A second set of plates is to be made, with an exposure of only ten or fifteen minutes, for measurement of the places of the brighter stars and the construction of a catalogue. It is estimated that this catalogue will contain 2,000,000 stars, while the chart will show not less than 20,000,000, and possibly 50,000,000 or 60,000,000. The whole work of taking the plates ought to be finished within about five years.

While the preparations for this great chart have been going on, Professor Pickering, of Harvard College Observatory, has been making one of his own with an eight-inch telescope of different construction, and bids fair to have it all done before the others have fairly begun. At present a party of Harvard observers is in Peru, making a survey of the southern heavens to join on with that already finished in the north. Mr. Isaac Roberts, in England, has, within the last three years, obtained some marvellously perfect pictures of the nebulæ and star-clusters with his twenty-inch reflector. Messrs. Barnard at Lick Observatory, Russell at Sydney (Australia), and Wolf at Heidelberg, have been doing some wonderful work with large portrait lenses and long exposures of from two to five hours. The last-named has even exposed one plate thirteen hours, bringing to light unsuspected details as to the structure of the stellar universe.

Lastly, I must mention the achievements of a young astronomer in Chicago, Mr. George E. Hale, director of the Kenwood Physical Observatory, who has, during the past year, discovered a method of photographing the coloured prominences of the edge of the sun without an eclipse, of photographing them all around the edge of the sun at one exposure, and of photographing the white spots, called faculæ, on all parts of the solar disc, whereas they have hitherto been visible only near the edge. The science is advancing so rapidly that it is difficult to keep pace with it. Each year, each month even, brings forth that which was unforeseen. That there are yet rich treasures in store for those who diligently search we can have no doubt.

H. C. Wilson.

DETECTIVE, HAND, AND MAGAZINE CAMERAS.

[Journal of the Photographic Society of India.]

The variety of the above-named class of cameras, with which the market is now stocked, is so great as to cause selection to be difficult. I have therefore put together a few observations which may assist an intending user in deciding what kind of camera he will buy or make.

I will deal first with the exposing shutter, with which all cameras of this class are provided. All are made to give very rapid and also time-exposures.

If the shutter, when set for a time-exposure, flies up with a jerk, remains open for such time as an elastic ball or a button be held pressed, and flies back with a jerk when the pressure is released, it will almost invariably shake the camera more or less, and the effect of the shake will be distinctly noticeable when a short exposure of less than two seconds is given. It is well, therefore, to have the power of exposing by hand—that is to say, by capping and uncapping the lens or aperture through which the lens looks.

If the exposure has to be made by pressing a button or pulling a string, the action is very likely to cause shake, whether the exposure be long or short, and whether the camera is held in the hand or attached to a stand. An exposure actuated by a pneumatic ball and tube is therefore preferable.

A hand camera may be of any size and any shape which it is pos-

sible for the operator to lift, point at the object, and fire off a shutter whilst so pointed, but it is likely to be an inconvenient companion of larger than half-plate size.

Any small camera with good light-tight slides or backs, and a quick shutter, will do as a hand camera. Some people like to have a finder, which can be easily attached; many prefer to work without any finder. I consider the finder exceedingly useful. Hand cameras may be divided into two classes—automatic and manual, both these classes including magazines. In the automatic class, a button or something is pulled or pushed, and a fresh plate from the magazine or reserve takes the place of the plate last exposed. In the manual class the plates may be carried in backs, and inserted or fitted to the camera in the usual way, or the exposed plate may be raised by a lever grasped by the hand and placed at the back of the reserve of plates, or the back plate of the reserve may be raised and placed in front of the last-exposed plate.

This latter plan is that adopted in one camera which has the following defects:—Unless the magazine is fully charged with the dozen plates or dummies, it will not work at all; and, if you want to expose only two plates, you must carry the weight of ten extra ones, for, if even one sheath is empty, the apparatus will not work.

Again, if you have twelve sensitive plates in the magazine, and, having exposed only one, wish to develop it at once, you must remove eleven plates to get at the one you want.

In another camera of this form this last defect does not exist, as it is the exposed plate which is removed and placed in rear of the unexposed lot.

In all cameras of this class, as well as in most of the automatic class, the plates are held in metal sheaths, and these sheaths, whether of zinc or iron, are liable to rust or oxidise, and the oxide comes off and makes spots on the plates.

Varnishing the sheaths is fatal, but the metal sheaths may be dipped in boiling paraffin wax, the surplus wax rubbed off, and this will, to a great extent, prevent the evil.

A convenient kind of hand camera which may be made by the amateur (with the exception of the carriers or dark slides) is a box camera with an ever-set shutter (such as the *Automatique*) fixed inside opposite the hole of the lens mount. The lens should screw on outside, as in any ordinary camera, and should have a rack and pinion or a draw tube for focussing, for, the camera being a mere box, no focussing can be done with it.

The length of the camera should be arranged so that, when the lens is racked or pushed right home, the plate shall be in focus for distant objects; and for nearer objects the lens can be extended, the focussing being done on a focussing screen as usual, or preferably by marks on the lens tube previously arranged for various distances. The plates are carried in dark backs, which slide or clamp into position. A leather handle on the top of the box facilitates carriage, and a screw-hole should be placed in the bottom and side of the box for use when it is desired to use a stand. The camera, if cunningly made, will carry a couple of extra dark backs inside, and can be fitted with finders inside or out. I consider this camera preferable to the kind in which an ordinary bellows camera is contained in a box with a hole in front for the lens to look out.

The best kind of dark back for a camera, such as I have described, is that in which the shutter of the back draws entirely out. Chadwick, of Manchester, makes a very superior camera of this class. It has, however, a bellows-body, and has to be "set up" each time it is required for use, so that it is not so constantly ready as the box I have described, but it has many qualities which render it superior to the box. It will take stereo pictures on a half-plate or on two quarter-plates, and it will take pictures the full size of the half-plate, and is, besides, a thoroughly good working camera for all sorts of work. The box form is superior only in solidity, simplicity, cheapness, and ever-readiness. Again, any camera may be fitted with a roll-holder, to carry a roll of sensitive film. No magazine camera yet devised can compare in convenience with this method, as the exposures can be made one after another with considerable rapidity, and the use of the film reduces the weight to a minimum.

Of this form of camera I have seen none to excel the Kodak. Of the automatic class, I know of none better than the Ideal. Of the manual class, I like Chadwick's, and a magazine camera made by Stirn on the principle of the Eureka. To sum up, in selecting a hand camera the following points should be considered:—

1. Is the arrangement for changing plates (whether automatic or manual) simple and certain in action?
2. Is there means of altering the focus?
3. Is there means to alter the aperture of lens?
4. Can the camera be used for ordinary work, such as enlarging, reducing, &c.?
5. Can the apparatus be carried about without inconvenience, and constantly ready for immediate use?
6. Is the instantaneous shutter of a type which is ever set ready for action which will not shake the camera in discharge, and which will admit of time exposures being given without shake?
7. Can the lens be easily removed for cleaning?
8. Is the instantaneous shutter totally devoid of indiarubber blinds or bands which will not stand a tropical climate?

According to the number of these questions which the camera will answer satisfactorily will, in my opinion, depend its utility.

J. C. Hannyngton.

THE ALLEGED FADING OF SILVER PRINTS.

Readers of the *Beacon* (says that journal) know that we have no great favour for silver prints, or, at least, the ordinary albumenised-paper variety, and believe that sooner or later—and think the sooner the better—they will, like many other once-popular things, be relegated to the limbo of forgetfulness.

But, although it has many faults, and no virtues equal to many, or least several, of its more modern competitors, that is no reason why it should be blamed for those it does not possess, or get a worse name than it deserves.

That some silver prints do fade, no one can doubt who looks into an ordinary photographic album, and we shall not be far from the mark if we say that a large majority of all those that have been made during the past fifteen or twenty years have faded more or less, or have within them the elements that lead to fading. Still, although ninety-nine out of a hundred may have given way, if the remaining one has stood the test of twenty years without deterioration, further than the natural yellowing of the paper on which it was printed, we are entitled to claim for silver prints a degree of permanency far beyond what is being generally ascribed to them.

That silver prints have been made that are practically permanent, we have abundant evidence both in our own and other collections. Lying before us while we write are some 9 × 11 prints from wax-paper negatives, made by ourselves at least thirty years ago, some from collodion negatives of a slightly more recent date, and some printed by the once well-known McGlashan, of Edinburgh, from negatives by Hill & Adamson, and they all seem as perfect as on the day they were produced, except for a allght mellowing or yellowing of the paper. Some are on plain paper, sensitised on an ammonio-nitrate bath, and some on home-albumenised paper, and all toned in one solution, the old fixing and toning bath.

Those were the days of dark tones, when the nearer to the appearance of an ordinary engraving the better we were pleased, and the negatives were dense and brilliant enough to admit of deep printing on paper strongly salted and sensitised on strong solutions. Some of the prints in our possession are in portfolios and some in frames, and several have crossed the Atlantic four times.

Our attention has been turned to this subject by the reading of a paper recently read by Mr. H. P. Robinson before the members of the London Camera Club, in which the cause of fading is laid on the shoulders of the chemists. He says, "The whole mischief has arisen from the interference and exceeding cleverness of [our chemists, and the progress of photography has been much retarded by the inventions of science," a statement which we are sure he will be inclined to modify on calm consideration.

As a proof of his contention that photographs made before the alleged unfavourable interference of the chemists were practically permanent, Mr. Robinson showed a copy of his well-known picture, *Fading Away*, which he declared to be as perfect as when printed, nearly thirty-five years ago. That it is so we do not doubt, but we are equally persuaded that such fading as may arise from the more recent methods devised by the chemists and scientists is not due to the use but to the abuse of those methods—to their ignorant or careless application.

In the face of much adverse criticism we have always thought well and spoken well of the old combined toning and fixing solution, and consequently are glad to see that Mr. Robinson's *Fading Away*, that has not faded, was so toned and fixed. The formula he gives is:—

Water	60 ounces.
Sodium hyposulphite	16 ,,
Chloride of gold	15 grains.
Nitrate of silver	15 ,,

which sometimes took the form of "a jug of water, a tube of gold, and a bit of nitrate of silver."

We do not suppose that photographers generally work thus by rule of thumb, but the most carefully compounded formula is just so much

labour in vain where its application is gone about in an ignorant or perfunctory way.

During the early days of photography, and especially with such prints as we have mentioned, the whole work was carried on with greater care and less haste than now. The prints were fewer in number and larger in size than is the present average, and each was specially and lovingly treated, generally by the photographer himself, who, as the prices were good and the orders confined to but a few copies, could afford to give to the work an amount of attentive care that would be out of the question under present circumstances.

To competition and its consequent low prices, then, we must, to a large extent, attribute the fading incident to faulty manipulation. To facilitate rapid printing, negatives are made so thin that only a slight surface reduction of silver is required to give the popular warm browns, and consequently the amount of gold which formerly was sufficient to protect the silver is reduced to the infinitesimal.

Then, instead of only a few prints, as in former times, they are now produced in large numbers, and fixed, probably several hundreds at a time, in one tray, and not unfrequently in a hypo solution that has been employed probably more than once before, and contains silver hyposulphite, and in consequence of the foolish addition of alum, free sulphur, which, when in a nascent state, may readily enter into combinations that lead to fading. With several hundreds of prints in one tray it is nearly impossible to prevent adhesion, or secure equal and thorough fixing, so that many are transferred to the washing machine still charged with silver hyposulphite, which, being insoluble, remains there ready to exercise its destructive action after many days.

There are no doubt other causes of fading that are beyond the control of even the most careful and intelligent photographer, but we must leave them for a future article, and conclude this by a strong plea for the more general employment of the "old fixing and toning bath." It has been thoughtlessly condemned as a method of sulphur toning, but is only so when used longer than it should be—used long after the gold is exhausted, and the hypo converted into the double salt of hypo and silver. It is not a difficult matter to ascertain how many sheets of any particular depth of printing may be toned by a fifteen-grain tube of gold; and if the photographer will make his negatives sufficiently dense to admit of deep printing, not on the surface merely, but right through the albumen, and tone them in a new combined bath, or one that has not been exhausted by too frequent use, he may rely on his pictures being practically permanent, so far as he and his work are concerned.

We have said nothing about washing, because we do not believe that many cases of fading occur from insufficiency of that operation. A properly fixed print may be sufficiently washed by eight or ten changes of water, with ten or fifteen minutes' soaking between each change. No amount of washing will remove silver hyposulphite from an insufficiently fixed print, and a too protracted soaking will do harm. Mr. Robinson says the good old way was to apply a drop of the washing water to the tongue, and if it did not taste sweet, washing was complete, and we are not sure that after all this if not satisfactory. The tongue is a delicate test, and would certainly detect any trace of the salt that could injure a print.

Our Editorial Table.

We have received the new catalogue of Mr. William Tylar, of Birmingham. In the course of about a hundred pages it gives illustrated particulars of his numerous and clever specialities, together with many other articles of photographic utility. Mr. Tylar's catalogue affords an excellent idea of how luxurious the pursuit of modern photography has been rendered by commercial enterprise. It is full of "good things."

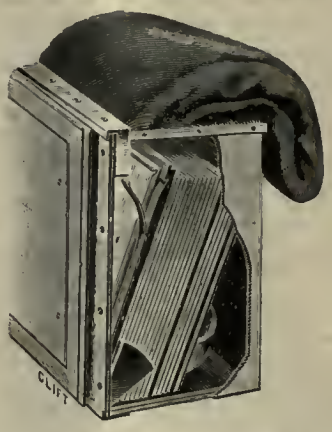
An "Outing Group."

For a year or two past the joint outing to the old-fashioned riverside suburb of Greenwich of those two admirable Societies, the Photographic Club and the London and Provincial Photographic Association, has been very popular with the members, our genial friend, Mr. A. Haddon, acting the part of the host in the domain of the Royal Naval College, and thus assuring the success of the gathering. On the occasion of the recent outing a 12 × 10 group of the members was taken under the direction of Mr. Haddon, which, considering the dull weather prevailing, is excellent. It includes, besides that of Mr. Haddon himself, portraits of several gentlemen whose names are familiar to readers of this Journal.

The "Kangaroo" Changing Box and Bag.

J. R. Gotz, 19, Buckingham-street, Strand.

This device for changing in the field possesses several highly novel points. It is intended for cut films, of which it will carry from two to three dozen in carriers, all or any number of which may be exposed and changed with remarkable facility. A single back of very slight width is employed, and this being placed *in situ* on the front of the box, at the rear of which are stacked the films, the method of filling the slide is as follows:—The hands being introduced into the bag on the top of the box, a trapdoor thereon is opened, the reeded shutter in front of the box is wound off, the shutter of the slide is released, being thrown back by springs as shown in the cut, and the first carrier containing a film being lifted up from the back is dropped



into its position in the slide, which, being closed, the reeded shutter is unwound, and the slide may then be withdrawn and used to expose the film in the camera in the ordinary way. To change the exposed film and substitute another, all that is necessary is to place the slide on the front of the box as before, draw off the reeded shutter, open the slide, withdraw the film, and place it at the back of the unexposed films, refill, and proceed as at first. A division at the back of the unexposed films separates them from those which have been exposed, so that no mistake is possible in distinguishing between exposed and unexposed. A whole-plate box and bag containing three dozen films weighs scarcely more than four slides containing eight glass plates, and measuring only about 10 × 8 × 4½ is easily carried. The Kangaroo is one of the simplest and most effective changing arrangements we have seen, and having recently had an opportunity of witnessing Mr. Gotz putting it to practical and successful service in the field, we are disposed to think that it will be found of very great use to those who desire to easily carry material for a large number of exposures with simple and reliable means for changing in the open.

Recepte und Tabellen fur Photographie und Reproductionstechnik.

By Dr. J. M. Eder. Halle-a-S.: William Knapp.

In this volume Dr. Eder has gathered together a collection of chemical and optical formulæ which completely traverse the entire field of practical photography. It should prove a most useful compilation to the busy photographer.

Improvements in Shutters for Photographic Cameras.

No. 17,516. John Edward Thornton and Edgar Pickard, St. Mary's-street, Deansgate, Manchester, Lancashire.—*August* 27, 1892.

This invention relates to what are known as "instantaneous shutters," and is designed with the object of providing such a shutter of simple construction, also of providing such shutters with an additional auxiliary or safety blind which will prevent light passing through whilst being set for exposure.

A box or frame, with an aperture or a perforated back and front of ordinary construction, carries both the exposing and the safety blinds, the former being mounted to run over one or two small rollers, one at each end of the box, and the latter attached to a spring roller at one end thereof.

The exposing blind is a square or rectangular piece of suitable opaque material, such as mackintosh, cloth, leather, or the like, of a size to cover either the back or front apertures. To one end of this opaque exposing blind two cords, chains, or strings are attached, which pass over the top roller and down through the bottom of the box, terminating in a ring, tassel, or knob; to the other end of this blind are attached or connected a spring or springs, preferably two fine steel spiral springs, which pass under the bottom roller and are carried upwards to the top of the box. Instead of these steel-wire springs, indiarubber springs may be used; or the blind may be attached, by means of cords or springs, to the barrel of a coiled or volute spring, or to a spring roller. Where the fine spiral springs are used, they may be fastened to the top of the box, or they may be connected to a cord or ring which can be drawn up and hooked over pins in various positions to vary the tension of the springs for the purpose of adjusting the speed of the shutter.

In the box between the top and bottom rollers we place a block or bar of wood or metal, either clear of the openings or with an aperture therein which corresponds therewith. On the back of this block or bar is placed a bevelled projection over which the blind slips, and catches on the underneath edge when drawn down to cover the apertures or close the shutter. A movable strip is hinged or pivoted between the block and the blind, by raising which the blind is lifted clear of the projecting catch and released for exposure. The strip may be lifted or moved by a cord, push, or pneumatic device of ordinary construction.

To the spring roller at the bottom of the box we attach one end of the safety blind, which is also of opaque material and of sufficient length when unwound to cover the opening in the box. To the other end of the safety blind we attach cords, chains, or strings which are passed over the top roller or through eyelets and down through the bottom of the box, where they connect with those attached to the other blind.

This safety blind may also be used with the blinds of instantaneous or time shutters, such as are at present in use, and it will also be obvious that the exposing blind herein described may be used without the safety blind, but at present we prefer to use the two together.

In operation, before exposure the exposing blind covers the front opening of the shutter, and the safety blind is wound upon the spring roller. To set the shutter, or adjust the blind for exposure, the two sets of cords are pulled together by the tassel. The two blinds are thus drawn forward at the same time, the end of one overlapping the end of the other, forming, as it were, one continuous blind. The cords are pulled until the exposing blind has passed from the back, over the top roller, to the front, whereupon it catches under the projection, and is held against the stress of the driving spring. It then covers the front aperture, so as to effectually exclude all light from passing through, and the safety blind, having served its purpose in covering the aperture until the exposing blind was in position, immediately, when the tassel is released, rewinds upon the spring roller. To make the exposure, the exposing blind is lifted clear of the projection by raising the hinged strip, and immediately the exposing blind flies back to its normal position, uncovering and recovering the aperture in its passage.

A shutter, with safety blind such as described, will be found especially suitable for hand cameras, though it will be useful for ordinary cameras.

The claims are:—1. A shutter for photographic cameras constructed with two flexible travelling blinds, one an exposing blind to open and close the lens or give an exposure when released, and the other an auxiliary safety blind to travel with and cover the edge or aperture of the exposing blind when it is being set to prevent light entering, and then return to its normal position. 2. A shutter for photographic cameras constructed with a flexible opaque exposure blind, which travels from the front to the back of the shutter over a small roller, to the corners of which are attached at one edge elongated springs, by which it is held and drawn back, and at the other edge cords, by which it is drawn forward, substantially as described. 3. A shutter for photographic cameras having an exposing blind, which travels from back to front of the shutter, actuated by elongated springs attached to the arms at one edge, and held in position when set by a projecting catch, with which one edge of the blind engages, and an auxiliary safety blind mounted on a spring roller, which is drawn forward across the lens with the exposing blind, and when released returns to its normal position, substantially as and for the purpose described.

Photographic Society of Great Britain.—The Technical Meeting, on September 27, will be held in the Gallery, 5A, Pall Mall East, at eight p.m. Subject, *Apparatus on View in the Exhibition.*

Leytonstone Camera Club.—The first annual competition and exhibition will take place at the Masonic Hall, High-road, Leytonstone, on November 10, 11, and 12, 1892. Open to amateurs only; professionals can exhibit, but not compete for prizes. Sixteen medals will be awarded, eight silver and eight bronze. The classes are:—*Members only:* A. Landscape, Seascape, and Architecture. B. Portraits and Figure Study. C. Enlargements. D. Lantern Slides (set of six). *Open:* E. Landscape, Seascape, and Architecture. F. Portraits and Figure Study. G. Enlargements. H. Lantern Slides (set of six). Entry forms and all other particulars may be obtained of Mr. A. E. Baller, Hon. Secretary Leytonstone Camera Club Exhibition Committee, Rose Bank, South West-road, Leytonstone, Essex.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

September 15,—Mr. E. J. Wall in the chair.

The Chairman made a large presentation of photographic literature to the Association, and was cordially thanked by the members.

The following question from the box was read:—"The following toning formula has been published in one or two American journals. One recommends it, and says it gives as permanent prints as gold toning; another says that prints toned with it will be quite fugitive. The formula consists of

Hypo	4 ounces.
Lead nitrate	30 grains.
Alum	½ ounce.
Sodium phosphate	10 grains.
Water	10 ounces.

The prints are not washed before toning, and are removed so soon as the desired colour is obtained."

Mr. A. Haddon did not think such prints would last very long.

The Chairman said that Valenta had referred to it, and said that sulphur toning was set up, and that the prints were not permanent.

Mr. Haddon passed round the negative, and prints therefrom, of the group of members of the London and Provincial Photographic Association and the Photographic Club on the occasion of the recent joint outing to Greenwich. In reference to the outing Mr. T. E. Freshwater described the occasion as an enjoyable one, and thought the thanks of those present were due to Mr. Haddon for his kindness in entertaining them. A cordial vote of thanks was therefore passed to Mr. Haddon.

American Plates and Printing Processes.

Dr. Charles L. Mitchell, of Philadelphia, who was present at the meeting, addressed the members on this subject, and mentioned the brands of plates mostly used in America, which he said were comparatively few. The 26 X of the Seed Company about corresponded in rapidity with most of the English drop-shutter plates; the 26 were about fifteen per cent. slower, and the 23 were of medium speed. Cramer, of St. Louis, used to make an immense variety of speeds, the fastest being almost impossible to use. When used properly, however, the results were good. He had since modified his sensitometer, and made three grades, A, B, and C, C being those used for extremely fast work. Mr. Carbutt made three kinds, Eclipse, Special, and B. The B were slow, the Eclipse very fast, and the Special half-way between. There were other makes, such as the Stanley, the Harvard, and the Eagle, the latter becoming quite popular with professionals. In films, Carbutt was perhaps the most successful. As regards printing methods, the most popular method was still albumen-silver, being largely used by professionals and amateurs. Within the last two years collodio and gelatino-chloride papers had, however, made very strong assaults on albumen paper, and had strongly diminished its popularity, a great many professionals using the two first named. The method of treating collodion paper with hot water had obviated its tendency to curl, the prints being just covered with the water, and allowed to remain in it for a few minutes, when the curl was removed. He (Dr. Mitchell) had found that curl decidedly objectionable. Bromide paper was much used for enlarging. Dr. Mitchell incidentally remarked that a 16 × 20 crayon enlargement and one dozen cabinets were supplied by many photographers through the agency of canvassers for as little as 15s., and in reference to the free crayon frauds, stated that the business in them had been, through legal agency, almost broken up. Platinum paper was used for fine work, although to a comparatively limited extent on account of the patent restrictions. There was no doubt, however, that for artistic and exhibition work it was superior to anything else in the way of printing surfaces. As regards methods of working, there was no difference between the two countries. The English photographic journals were very closely scanned by enterprising editors on the other side. He would like to see more uniformity in the size of plates, and would be glad if American and English photographers united on the point, so that there would be no difficulty in getting one's size of plates away from home. He preferred the American lantern size (4 × 3½) on account of the extra room which it gave for titles and comprehensive labels. In conclusion, he expressed the conviction that next year visitors to the Chicago Exhibition would not find the New York Custom House as bad as hitherto; it was nothing like so bad as it was represented.

Mr. R. P. Drage asked Dr. Mitchell if celluloid films were much used in the United States?

Dr. MITCHELL said that for amateur work they were displacing glass. Of course the perfection of the film depended upon the perfection of the celluloid, the preparation of which he described.

Mr. ALEXANDER COWAN asked if Dr. Mitchell could say why the Americans did not, could not, or would not use ammonia in the developer.

Dr. MITCHELL replied that he had been told that American plates would not stand ammonia; American photographers did not like the deep yellow tinge got by using pyro and ammonia. In reply to another question, he said that hydroquinone and eikonogen were used a great deal by amateurs, but that professionals preferred pyro-soda.

Mr. H. SNOWDEN WARD stated that when in New York he had seen the hot water toning method for collodio-chloride paper in operation at Messrs. Anthony's establishment. There was no trouble with curling or buckling, and the prints toned very quickly to a warm purple, although it was stated that practically any tone could be got. There was a richness and beauty about the paper that did not exist here in any paper with enamelled surface.

After further discussion, the CHAIRMAN, in moving a vote of thanks to Dr. Mitchell, which was carried, referred to the specimen gelatine and collotype prints given in the American magazines, which were quite equal to anything produced in England. The photogravures were perhaps not quite so good. Referring to the combined toning and fixing bath containing lead but not gold, he quoted Valenta as saying that the lead kept the whites clear, and caused sulphur toning. Gold and lead toned prints had been exposed to ozonised air, and the latter did not stand very well. In conclusion, the Chairman reminded the meeting of what the Brussels Congress and the Photographic Society of Great Britain had done as to the proposed standard size of plates.

AMIDOL.

Mr. E. W. PARFITT exhibited a small bottle containing some stock solution of amidol, made according to the usual formula. When prepared a fortnight previous, the solution was quite colourless, but it had since turned brown, and considerably slowed in action. The water was not boiled.

Mr. COWAN produced the bottle of solution which he had used for developing twelve plates three weeks ago, and that had not discoloured at all.

Mr. P. EVERITT had prepared some amidol solution with boiling water, and it had not discoloured.

Mr. HADDON had had some of the developer in an open developiug glass for two days, and it had not changed its colour.

Mr. T. E. FRESHWATER had prepared some solution by means of distilled water, and it had not discoloured.

The CHAIRMAN, on the other hand, had found a three weeks' old solution had discoloured, although he had used distilled water.

On the invitation of Mr. DRAGE (the Hon. Secretary), Dr. MITCHELL described the method of conducting American photographic societies, saying that they were, as a rule, more formal than the English societies. For his part he preferred the way in which the English societies were conducted—there was more freedom.

The meeting shortly afterwards terminated.

Hackney Photographic Society.—September 13, Mr. W. P. Dando in the chair.—Mr. SODEAU explained the use of blue glass in the testing of safety of the dark-room light. Messrs. Pollard, Grant, Dean, and Roberts showed work. Mr. Roberts showed some Ilford paper toned with Mr. Welford's bath, and good results were obtained. A lengthy discussion on the exhibition took place, and it was finally resolved that no member should be allowed to compete who has not attended meetings at least four times during the last twelve months. Members were advised to send in a list of proposed exhibits in order as they thought best, so that the hanging committee could be guided in selection. Dr. Colquohoun then gave a short demonstration with amidol. He has used it regularly since August, and was much pleased with it. In cases of under-exposure it was very valuable. Mr. Sodeau exhibited a plate he had developed with it. The exposure was one-twenty-fifth of a second, on a London street, at *f*-11 on a dull day, but it had come out very satisfactorily. Dr. Colquohoun then developed some films, using on the last done a solution of chloride of aluminium, which he said hardened the film to such an extent that it could be washed in hot water.

Putney Photographic Society.—Members of this Society met on Wimbledon Common on Saturday last, and were favoured with lovely weather. Successful negatives were taken of the firing parties at the various ranges, as well as of the golfers who frequent this common in large numbers, and whose characteristic attitudes form good subjects for snapshots. At the invitation of Mr. Faulkner, member of the Council, the party proceeded to his house at Roehampton, where they were entertained. The remainder of the afternoon was spent in photographing in the grounds and palm houses. This was the last of the summer outings of the present season and a worthy finish to the series. The winter season opens on Monday, October 10, when a social meeting will be held in the rooms of the Society in the Charlwood Road, at eight p.m.

Newcastle-on-Tyne and Northern Counties' Photographic Association.—September 15, the last outdoor meeting of the season was held. The party, driving in brakes from Gilsland, visited Birdoswald, Coom Craig, Lanercast Priory, and Naworth Castle. The weather was favourable, and a very enjoyable day resulted. Mr. M. Auty acted as leader in his usual thorough manner.

Correspondence.

PHOTOGRAPHY BY RULE.

To the EDITOR.

SIR,—Mr. Bedding accepts my assurance that I am "unbiassed," although seemingly not "unprejudiced."

I fail to see the difference, and as he again and again makes such assertions, instead of arguing the matter fairly, I should like to make a personal explanation.

In the spring before last my attention was called to the researches of Messrs. Hurter & Driffield, published about a year previously. I gave their work my close study, and was astonished that it had not been brought under the notice of photographers in general. I prepared an abstract of their paper, which you did me the honour to publish.

I found that their theory gave a new light to many photographic problems, and I caused instruments to be made for my own use and for further verification and investigation. This, I submit, was not the action of bias or prejudice; it was prompted solely by the wish to examine, and profit by, the highest scientific researches which had fallen under my notice. Later on, I found that the public were wishful to know the speed of their plates, and, having the necessary instruments at hand, I responded to the demand. I am unwilling to intrude these matters on your readers, but the whole history of my connexion with quantitative photography shows not prejudice, but the reverse, when examined step by step. Had I been prejudiced I should have despised every other attempt to construct an actinometer or exposure table; but I have always approved any sensible effort to guide the young or the occasional worker in the matter of exposure.

Mr. Bedding's central contention is as follows:—"Your measurements of intensity of light, area of diaphragm, speed of plate, absorption of lens, are all subject to error; then why measure at all?" He might as well ask his tailor the same question, and I would give him his tailor's reply. No measurements whatever are free from error, and I have been careful to admit that they are but approximate; but the "judgment" must be "mellow" indeed that can give greater accuracy. "Oh," says Mr. Bedding, "but I can modify my development to suit the case of over or under-exposure; this, too, requires learning, but experience will make you perfect." His argument cuts its own throat. We all know of the clerk whose expertness in "scratching out" prevented his obtaining the situation; so this aptitude in dodging development condemns the "judgment" theory of exposure.

There is, indeed, a seeming paradox, which is a real difficulty to many, the reconciliation of "correct exposure" and "latitude." I can here only touch on the subject as far as it is pertinent to the discussion in hand, as the full exposition would trespass too much on your space. Here is a slow plate, and here is an object of small degree of contrast. Any exposure, in a definite light, between, say, two and *forty* seconds gives an *equally correct* negative. With an object of greater contrast, by adding lighter tints, any exposure between two and *twenty* seconds is equally admissible. With greater contrast of subject, the limits of correct exposure are narrowed, until at last two seconds is the *only* correct exposure. With still greater contrasts the plate refuses to give a correct representation of all the tints of the subject.

As far as I know, from this law there is no escape, and it shows why, and to what extent, an experienced guess may serve the practical requirements of the photographer. The anomalies and contradictions which are thus explained are too numerous for me to refer to; they will readily suggest themselves to any thoughtful reader of the JOURNAL. And this result, of such deep importance, could never have been reached but for the quantitative researches with which I am proud to be, even remotely, associated.

The reason will now be seen why the combined errors of a calculated exposure so seldom throw the result beyond the limits of latitude of the plate, placing the beginner or the *occasional worker* on a par if not in advance of the constant operator, especially when using different types of plates for various requisites.

It is asserted that some plates become faster by keeping; others slower; that a yellow lens absorbs twenty-five per cent. of the light through colour alone. How are these things known, if true? By the exposure proving erroneous. Judgment has been found at fault. The experienced worker has made a mistake.

But by calculated exposures such errors are much more easily traced to their origin, and allowed for in future. Indeed, unless the exposures are calculated, it is rash to say that the speed of the plates has varied, or how much per cent. the lens absorbs.

Mr. Bedding's original paper makes no mention of makers' descriptions of plates. He says it was, *in short*, "by comparing the exposure about to be given with that previously given under similar or different conditions, as the case may be, that experience was gained," leaving untouched the determination of the exposure *about to be given*. Otherwise, by trial and error in exposure, experience is gained; by experience, judgment in exposure is acquired. Therefore, correct exposure is founded on trial and error. Moreover, the conditions of which he speaks are the varying appearance of the focussing screen. Surely, sir, I may conclude with the old adage, "Who will to Cupar maun to Cupar."—I am, yours, &c.,

R. C. PHILLIPS.

The Arts Club, Manchester, September 19, 1892.

[This matter has now been fully dealt with, and here terminates.—ED.]

"COOL WATERS."

To the EDITOR.

SIR,—In your last issue you publish a letter from Mr. Henry Whitfield *re* "Photography and the Illustrated Press," wherein we are accused of describing a picture (published in the *Illustrated London News* o

August 7 last) "as by ourselves," whereas he claims to have produced the negative.

This is the first intimation we have ever had that Mr. Whitfield had anything to do with it, but nevertheless we entirely deny ever having described it as being by ourselves, or in any way suggested or implied the same at any time, notwithstanding our legal purchased right to have done so had we been so disposed.

The facts of the case are as follows:—Some few months since we purchased from Mr. J. Vaughan the business, negatives, and all appertaining thereto, knowing nothing of Mr. Whitfield. Exhibited in the window (where it had been for some years) was the picture *Cool Waters*, with the encloeed printed ticket attached: "Photographed from nature and enlarged by J. Vaughan." A member of the firm of "Ross's" Electrotype Agency, Fleet-street, E.C., inquired whether we had any pictures of a similar nature that they could make use of. We explained that, having only just purchased, we scarcely knew, but would communicate. We submitted several. *Cool Waters* was selected, and a sum offered for *the sole copyright*. We replied that we could not undertake to grant sole right, as we were not aware as to what had been done by our predecessor, who made the negative, but would accept the sum named for whatever right we had in the picture for any purpose they might require.

We heard nothing more of the matter until the picture appeared in the *Illustrated London News*, when we were much surprised and not altogether gratified.

We beg to protest against the manner in which Mr. Whitfield has brought the charge against us without first making some attempt to ascertain the facts.—We are, yours, &c., MORGAN & Co.

119, *Old Christ Church-road, Bournemouth, September* 17, 1892.

To the EDITOR.

SIR,—Referring to the letter which appeared in your last week's issue from Mr. Whitfield, may we say that, as we were instrumental in the publication of the picture in question in the *Illustrated London News*, and as we knew nothing of Mr. Whitfield in the matter, we requested the paper to acknowledge Messrs. Morgan & Co., of Bournemouth, as the photographers from whom we obtained the original, since they were the owners of the picture, and the only persons whose names we knew in connexion with it? This acknowledgment of Messrs. Morgan & Co. was not made at their request, nor with their knowledge, but simply out of courtesy, in our usual form.—We are, yours, &c., NOPS & TARRANT.

19, *Ludgate Hill, September* 20, 1892.

HOW TO GET A GOLD MEDAL.

To the EDITOR.

SIR,—On my return from the seaside I found the enclosed from the Académie Parisienne des Inventeurs. I should very much like to sign my name with a good long tail to it, but not at my own expense; therefore, should you feel inclined to make me a nice Christmas-box, you can do so by following E. Boettcher's instructions. Use the enclosed as you may think proper.—I am, yours, &c., JOSEPH GEORGE HUDSON.

4, *Randolph-gardens, Maida Vale, September* 16, 1892.

[The following is an extract from the invitation which was sent to our correspondent.—ED.]

"PARISIAN INVENTORS ACADEMY.

"*Paris, September* 5, 1892.

"J. G. Hudson, Esq.

"SIR,—We beg to inform you that the Academy has conferred upon you the title of Honorary Member (Membre d'Honneur), with award of the first-class diploma and the great gold medal (gilded).

"This honourable title will be of no expense to you, but if you are desirous to receive the medal and diploma you would have to send us a post money order, to be paid in Paris, of 2*l.* (or bank-notes per registered letter) to cover admission taxes, freight, &c., and we shall send both well packed and free of charge to your address."

The following are the objects of the Academy:—

"1. To contribute to the progress of all which concerns public prosperity.

"2. To discuss the value of the latest inventions and discoveries, and to assist inventors by its influence, its relations, &c., to find the proper ways and means to draw benefit from their inventions and innovations.

"3. To entertain relations to be followed up by a brotherly spirit between all its members."

ACCURACY OF PHOTOGRAPHIC APPARATUS.

To the EDITOR.

SIR,—I read with interest your article on "Accuracy of Photographic Apparatus," as I have lately been suffering from the want of it. I have just returned from the neighbourhood of the Matterhorn, an out-of-the-way part of Switzerland, in a photographic sense, as there were no shops to replace faulty apparatus, or buy anything connected with photography. I had taken with me several packets of cut films, with which I had great trouble, as some of them were cut one-eighth of an inch too small, with the result that they either would not remain in the holder, or else, when the slide was drawn, it was impossible to push it back, and the film either fell into the body of the camera or was crumpled up. I wonder if any of your readers have suffered in the same way. The trouble with the turn-back pin is one from which I have suffered for a long time, and it has always been a wonder to me that the makers do not put a slight depression with a file, or finish off with a swallow-tail instead of a point, in either of which the nail would easily catch. I enclose my card, and am, yours, &c., M.

September 16, 1892.

AFFILIATION OF SOCIETIES' SCHEME.

To the EDITOR.

SIR,—It has appeared to me for some time past that, with the powerful assistance of the photographic Press (which seems to be seldom invoked in vain), the practical usefulness of the host of Societies throughout the United Kingdom might be greatly extended, if some system of reciprocity could be introduced with regard to the use of dark rooms by visitors, and their admittance to meetings, excursions, &c.

Enclosed is a copy of the prospectus and rules of the Cheltenham Amateur Photographic Society, giving particulars of what this Society is willing to offer to the members of any other Society who will give in return such conveniences as they may possess for the use of our members. Visitors should be armed with a card of introduction from their Secretaries, such as I enclose herewith.

To put the scheme into practice, I propose that the Secretaries of such Societies as are willing to throw their premises open to all other Societies who reciprocate, should write to me, giving particulars of the conveniencies which visitors may expect to find there. These Societies would then be classified, and I would send a full list to the photographic journals. All the Secretaries interested would then be put in possession of the fullest particulars of the resources of each Society affiliated. A system of freemasonry would thus be initiated, which could not fail to make the practice of amateur photography still more pleasant and fascinating. Most of us, when visiting a strange town, will appreciate the advantage of being able to change plates, and possibly develop, without fuss or favour, to say nothing of the introductions to local amateurs, in a position to give much useful local information and assistance.

I cannot but think that, if this idea be carried out, and, perhaps, enlarged upon later, it must prove of general benefit, and, perhaps, do something towards preventing the disappearance of some of those Societies which are missed from our midst from time to time.

I see no reason why such affiliation should be restricted to British Societies only; for instance, will Chicago Societies reciprocate? Perhaps members of Societies will draw the attention of their Secretaries to this letter, and urge action? Thanking you in anticipation, I am, yours, &c., PHILIP THOMAS,

Secretary, Cheltenham Amateur Photographic Society.

Bath-road, Cheltenham, September 17, 1892.

EXETER AMATEUR PHOTOGRAPHIC SOCIETY'S EXHIBITION

To the EDITOR.

SIR,—We are arranging an exhibition for the last week in November, full details of which will appear later on. It will be open to all, amateurs and professionals, but the former only will be eligible for the competitions. If you will kindly give publicity to this, we shall esteem it a great favour.—I am, yours, &c., JOHN SPARSHATT, *Hon. Secretary.*

Fairfield House, Alphington-road, Exeter, September 18, 1892.

HACKNEY PHOTOGRAPHIC SOCIETY EXHIBITION.

To the EDITOR.

SIR,—This Exhibition will be held on Tuesday, Wednesday, and Thursday, November 15th, 16th, and 17th, 1892, at Morley Hall, Hackney. The judges will be, in all probability, Captain Abney, F.R.S., &c., and Messrs. Ralph W. Robinson and J. Gale. The open classes will be: 1. Stereoscopic; 2, Portraiture and Genre; 3, Lantern slides; and, 4, Landscape. Entry forms will be ready by next week. Application for space for apparatus, &c., is required as early as possible.—I am, yours, &c.

September 19, 1892. W. FENTON JONES, *Hon. Sec.*

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—September 27, Social Meeting. October 4, *Manipulation of Gelatino-Chloride Paper*, by Mr. E. Underwood. 11, *Self-help for Amateurs*, by Mr. W. B. Osborn. 18, Prize Slides. 25, *Lantern Slide Making*, by Mr. E. H. Jaques. At some subsequent date it is proposed to have a lantern display of subjects taken on excursions during the last season.

THE Thornton-Pickard Manufacturing Company announce that they have completed the erection of their new factory and offices at Altrincham, near Manchester, and that the whole of their business will be transferred to the new premises from September 24, after which all communications should be sent to the new address. The factory has been designed and built expressly for the manufacture of the Thornton-Pickard specialities.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, *including queries for "Answers" and "Exchanges," must be addressed to* "THE EDITOR," 2, *York-street, Covent Garden, London. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.*

*** *Communications relating to Advertisements and general business affairs must be addressed to* "HENRY GREENWOOD & CO.," 2, *York-street, Covent Garden, London.*

PHOTOGRAPHS REGISTERED:

Goodwin Thorley, Long Eaton.—*Photograph of Long Eaton Waterworks, with group in front of building.*

J. Bell, Frome.—*Photograph of the interior of St. John's Parish Church, Frome, Somerset, and of the high altar of St. John's Parish Church, Frome.*

W. GRIFFITHS.—Thanks; the date named will do perfectly well.

CAPTAIN J. HOPE.—The scratches may be removed from the surface of ebonite by polishing.

W. S. VEDDIE.—Abney's *Instruction in Photography* would probably suit your purpose.

J. D. TRINGROVE (Peterborough).—By reproducing or selling the picture you render yourself liable to prosecution.

RECEIVED.—*Dry Plates*, edited by Cadett & Neall; *The Hand Camera, and How to Use it*, by Walter D. Welford. These and others in our next.

TWO YEARS' SUBSCRIBER.—If you write to Messrs. Newman & Guardia, Farringdon-road, E.C., they would give you the information required.

F. W. BOCKEN.—We should think that the light from either a coal or coke fire, if it gained access to either sensitive plates or papers, would fog the pictures.

SERGEANT-MAJOR.—We presume there would be no objection to your taking photographs in Kew Gardens while wearing your uniform, provided you have the ordinary permit to photograph in the gardens and houses.

C. BREWER.—It is tolerably well known that the xylonite dishes are not adapted for holding methylated spirit, inasmuch as that material is soluble in it. You now see the reason why your tray has "come to grief."

STELLA.—The minute transparent specks on the negatives arise from dust on the plates. Before putting them in the sheaths, carefully dust them with a broad camel's-hair brush. Also, well dust the inside of the apparatus.

R. A. J.—If the enlargement has turned yellow in less than three months, we should say that you would be perfectly justified in returning it to the maker for replacement, in the same manner as your customer has done to you.

A. E. BAILEY (Hon. Secretary, Leytonstone Camera Club).—The notice of your exhibition was crowded out last week. We are sorry we cannot undertake to distribute the entry forms. Terms for advertising have been sent you.

REV. DR. R. O. DAVIES.—1. At p. 783 of the ALMANAC for 1892 the formulæ of several hypo eliminators are given. 2. *Hot* water would obviously not answer for a printing-out paper in which gelatine is employed as a vehicle.

B. A. S.—A lens with an aperture of *f*-6 will be quite quick enough for out-door work with a drop shutter, in an average light, with plates of extra rapid kind. With a little practice, a whole-plate camera can be used successfully as a hand camera.

T. BLOOM.—If your query was not replied to it was because you did not append your name and address: consequently the letter was consigned to the waste-paper basket. Repeat your question. The answer can appear under initials or a *nom-de-plume*

W. A.—From your description we think that if the negatives were placed in a clearing solution, say a saturated solution of alum with an ounce of hydrochloric acid to the pint, for an hour or two, they might become printable. Try with one or two.

H. W. KEAST.—Your employer will have to pay your full salary up to the time that the notice expires. Unless there was an agreement to that effect, he is not bound to pay your fare back. If you summon him, and gain your case, the Court will allow you costs.

H. C.—Without an analysis it is impossible to say what is the cause of the spots which appear after mounting. There are many other causes of spots than bronze powder. Better place some of the prints and some of the mounts in the hands of an analytical chemist for examination and report.

S. S.—It by no means follows that because albumenised paper has an offensive smell it is prepared with blood albumen, though such is, to a certain extent, a popular fallacy. Notwithstanding that the paper you are employing "stinks abominably," it may be prepared with nothing but whites of eggs.

D. SUCH.—The blurred effect on the windows is halation. If the plates had been backed, as all plates should be that are used on interiors, the trouble would be avoided. As the negatives have to be taken again of a different size, back them by any of the well-known methods, and good results will be obtained.

T. WORLEY.—The best way we know of cleaning the gelatine films from old negatives is to soak them in cold water for a day or so, and then immerse them in hot water. Hydrofluoric acid may be employed, but it is very unpleasant stuff to use. We should recommend the purely hydropathic treatment.

A. H. DE ATH.—The markings are clearly due to the manipulations. They are entirely on the surface of the print, and some of them are decided finger-marks. By treating the print with a sponge and cold water the whole of the marks were removed, and the surface left perfectly clear and bright. The picture apparently has been over-toned.

A. SIMMONS.—The mere registration of a picture at Stationers' Hall does not thereby confer copyright, unless the Act has in other respects been complied with. In the first place, did you receive pay, and were you authorised in writing by the sitters to copyright their portraits? If you have complied with these conditions, you have a clear case against the pirates.

MR. WILSON NOBLE, M.P., writes: "Can you tell me where the hypo and meta-bisulphite cartridges mentioned by Miss Ethel Constance May are to be obtained? Anything that gets rid of the nuisance of weighing hypo must be a boon."—So far as we are aware, the cartridges are not articles of commerce in this country. They are, we believe, used in Austria and Germany.

BELLA.—Immersing albumen prints in a strong solution of alum after they are taken from the fixing bath will not prevent blisters. The treatment the print has been subjected to will fully account for its stained and yellow appearance. Blisters may be avoided by immersing the prints when they are taken from the frame, prior to washing, in methylated spirit. This preventive has never failed in our hands.

EXPAND says: "I have mounted a number of platinotype specimens on good platinotype mounts, gold bevel edge, and exposed them in my window uncovered. The flies have spitted over them nicely, and unless something will remove these spots, prints and mounts will be useless. Have tried cold water and sponge. Can you tell me what will remove this trouble without spoiling surface of mounts or prints?"—If a sponge and cold water will not remove the trouble, we know of nothing that will. Prints of this kind should always be protected by glass, particularly at this time of year.

OTHELLO writes as follows: "I have found a great difficulty occur in my use of the new gelatine printing papers. It is the spotting. In the rush of business I cannot afford to take them from the washing water and dry before spotting. This might answer, but I always prefer to squeegee them direct on collodionised glass. (I invariably use collodion on the surface to protect from future moist and dirty fingers.) I have spent several shillings in mediums, &c., that are supposed to dry bright, but in my hands they have all failed, leaving unmistakable evidence of their application on the collodion surface. I fancy I have heard or read of a formula for a spotting medium that contains gum senegal, which could be used on the collodion surface without disfiguring it. If you or your readers could give me any information on this subject, I should be greatly obliged."—Perhaps some of our readers will assist "Othello" in his difficulty.

THE new address of the Liverpool Amateur Photographic Association is Percy-buildings, Eberle-street, Liverpool.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—October 4, Lantern Night. 18, Technical Evening. Nominations for Council and officers for ensuing year for election at Annual Meeting. November 1, Annual General Meeting.

THE London agency of Messrs. Walter Griffiths & Co., of Birmingham, has been placed in the hands of Mr. L. E. Morgan (late of the Fry Manufacturing Company), to whom communications should be addressed at 5, Agar-street, Charing-cross, W.C.

THE Leigh Photographic Society are to have a lecture room and dark room in the new Technical School at Leigh, the foundation-stone of which was laid on the 10th inst. by the Hon. L. Powys. The first annual meeting of the Society will be held on the 29th inst.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—September 29, *A New Gelatine Emulsion for Lantern Slides*, by Mr. G. T. Harris, with specimens. 24, Outing, Hadley Wood. October 6, *Various Printing Processes*, by Mr. B. Foulkes Winks.

MR. W. D. WELFORD informs us that he has received from the Secretary of the Queen of the Belgians a kind letter, in which he is instructed to express Her Majesty's great admiration of Mr. Welford's Belgian street scenes, taken with a hand camera, in the use of which Mr. Welford is known to be proficient.

IN connexion with the evening classes of the City of London Young Men's Christian Association, Mr. B. Foulkes Winks is to give, commencing with the evening of Thursday, September 29, a course of instruction in Photography, and will be happy to forward tickets of admission for the introductory lecture on the above date.

THE PHOTOGRAPHIC CLUB.—September 28, *The Object of Photography*, by Miss Catharine Weed Barnes. October 5 first Lantern Night of the season; slides from negatives taken during the Edinburgh Convention meeting. Outing, Saturday next, September 24, Hadley Woods; meet at High Barnet Station between two and fifteen minutes past two.

WE have received the calendar and syllabus of the evening classes in connexion with the People's Palace Technical Schools. The elementary and advanced courses of Technical Photography are under the direction of Mr. Charles W. Gamble, the instructor in Retouching being Mr. Wolfgang Arndt. The syllabus of these two courses is set forth in such detail as to leave no doubt that the subject is fully dealt with in all its many departments.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 1691. Vol. XXXIX.—SEPTEMBER 30, 1892.

THE PHOTOGRAPHIC EXHIBITION.

The Exhibition of the Photographic Society of Great Britain serves as a watch-tower from which, year after year, we may note the advances that have been made. It was on this, as on former occasions, formally opened by a soirée which was numerously attended by members and friends, some of whom had travelled great distances to be present. They were received by Captain Abney, F.R.S., President of the Society, and Mrs. Abney, together with some of the members of Council.

The crush, not usually accounted unpleasant, was as great as ever, and the accustomed query, "Is the show up to the average?" received an emphatic affirmative response, one member's inquiry as to what his interlocutor thought of the "Shipwreck" being received with the smile of confidence which the irony demanded. Indeed, so great was the number of pictures sent in, that about one-third of the whole was of necessity rejected. We think we are correct in saying that the verdict of the Judges has on the whole met with general approval, though in one or two particular instances it was suggested that a bestowal of awards in another direction might have been justified on the merits of the case.

The first thing noticeable in the Exhibition is the variety of tones which the pictures present. While ordinary platinum tones still hold their own, there are a greater number of sepia prints than on any previous occasion. We have several times spoken of how well this colour lends itself to the production of photographs on rough-surface paper. Carbon printing, which during the last and preceding year seemed to be lagging behind, is, we are glad to see, here to the front in considerable force.

Technical merit had some years since taken such a high place as to leave but little room for any great advance being made; but it is gratifying to find that photographers have gone with a steady aim at improving the art qualities of their exhibits; indeed, it may fairly be said that in this respect the present Exhibition shows an advance on all previous ones. We observe, as conspicuous by absence, very few illustrations of snap-shots taken by hand cameras. We have heard that several were sent in, but that, possibly from want of wall-space or from intrinsic demerits, the Selecting Committee had to leave them out. Let us hope that in another year, by which time it is expected that the present Exhibition room will not be at the service of the Photographic Society of Great Britain, another both larger and better-appointed gallery will be secured, and also in virtue of greater art experience, it will not then be necessary to say, as on the present occasion, that such a large percentage of all the pictures sent in were reluctantly unhung.

The newspaper press has, with perhaps a solitary exception, spoken of the Exhibition in highly favourable terms. That exception is the *Times*, a perusal of its article instantly establishing the fact of the absence of its quondam skilful and, scholarly critic (Sir Henry Trueman Wood), whose able descriptive and critical remarks in former years stand out in all the brighter and bolder relief on account of his absence.

The lantern transparencies this year, both in tone, gradation and composition, are of a high order of merit; but it is to be regretted that the exhibition of lanterns themselves and other lantern appliances is so sparse. This regret extends to all the mechanical section. The quality, however, in this department is so good as to somewhat make amends for the paucity of exhibits.

With the few exceptions above enumerated, we are happy to recognise in the present Exhibition qualities which compel us to regard its future with unalloyed confidence. The critic we have already noticed is pleased to decry the art merits of the Exhibition, but the refutation of such an interested disparagement will be apparent to all who will give an intelligent inspection to the pictures on the walls; for we take leave to say that the progress of art photography is not dependent upon the productions or good countenance of two or three workers having not generally recognised views on the focal treatment of subjects; and, as for the fact of their abstention from such an Exhibition as that under review having anything but the smallest influence in any respect, the idea is too absurd to be entertained.

To sum up, the current Exhibition of the Photographic Society must be set down as an unqualified success. Portraiture ranks as highly as ever in its two dominant schools of touched and untouched work, while the treatment of landscape work, in its different varieties of focal and tone renderings, provides a diversified display which, while it may give rise to animated discussion, above all attests the marvellous and constantly expanding powers of photography in transcribing nature in all its illimitable phases. Architectural photography, interiors, the scientific applications of photography, photo-mechanical work, humour, composition, and a laudable degree of technical skill, find the highest forms of treatment in the Exhibition, the uniform success of which we are sure will constitute a landmark, both in the history of photography and of the Society which has gathered it together.

RESTORING FADED ALBUMEN PRINTS.

THERE are few of our readers, we imagine, who have not in their collection of photographs some which have passed or are passing into the "sere and yellow" stage, and in a great many instances, no doubt, the means of restoring a valued portrait to its pristine condition, or of saving it from getting worse, would be welcomed, if such were available. It is quite true such methods do exist, but they are only to be relied upon in the most skilful hands, and at best give but an unsatisfactory result.

The most familiar of the old-fashioned methods consists in treating the print with bichloride of mercury, and afterwards with one or other of a variety of substances familiar to the worker of dry plates in connexion with mercurial intensification, the process of restoration being, in fact, almost identical with the latter. By treatment with the mercurial salt, the faded or yellowed image becomes further bleached, and apparently almost destroyed, owing to the conversion of the silver, of which it is chiefly formed, into a white or nearly white chloride; but the application of a second solution, say, of very weak hypo, again darkens it by conversion into a sulphide in which silver and mercury exist together, and which form a vigorous and not altogether unpleasing image.

The colour of such converted images is, however, invariably of a brown tone, though it is not easy to secure with certainty any particular tint that may be desired, and the result is as likely to be unsatisfactory as not, more especially in these days, when brown tones are not universally admired. Besides which, a strong prejudice exists against the use of mercury in this manner on account of an imaginary want of permanency of the restored image. This suspicion is, however, so far as we know, entirely ungrounded; for if the print be properly treated, that is to say, carefully washed between the various operations, the resulting image may be relied upon as consisting of an almost unchangeable compound, while the whites of the picture are at least in no worse condition as regards liability to discolouration than they were before the treatment.

A similar process, and one which possesses advantages over the mercurial method, though it has not, we believe, been generally applied to this purpose, consists in the substitution of perchloride of copper for the chloride of mercury in the primary bleaching of the image. This acts in a precisely similar manner, converting the silver image into one of compound chloride of silver and copper, which is amenable to the same modes of after-treatment as the one composed of mercury. But the preferential plan of reduction, when the cupric chloride is used, is to apply one of the ordinary developers used for dry plates, only taking care that it is considerably diluted and restrained, and of such a nature as not to stain the paper. In this manner a very considerable variety of tone may be obtained, both by changing the developer and by varying its strength, and the process is free from the unfortunate suspicion of want of permanency that attaches to the method just mentioned.

A serious drawback to the use of the copper salt is found, however, in the persistency with which it clings to the print, not only in the soluble condition in which it exists in the solution, but also, it is to be feared, in an insoluble state, or nearly so, as cuprous chloride, which, though colourless, or nearly so, in itself, is subject to reduction on the subsequent application of the developer, and so causing discolouration of the whites of the print. This danger is minimised by slightly acidifying the bleaching solution with hydrochloric acid, which prevents the formation of the subchloride, and by copious and careful washing of the print after treatment, under which conditions no discolouration of the whites will occur.

When the details of the copper process are carefully and intelligently carried out, it is possible, as already stated, to secure a great variety of tones, from warm to neutral black, though, perhaps, it would be inaccurate to claim that any individual colour can be secured or repeated with absolute certainty. We were at one time of opinion that the colour might be varied by giving the bleached print a more or less prolonged exposure to light before reduction, so as to produce the same effect as is obtained by varying the exposure of chloride prints; but a more careful scrutiny of the results obtained have convinced us that the presence of copper in the bleached and nearly invisible image altogether upsets the reliability of any such expectations.

What is really required, then, would seem to be a method by which the image can be converted into pure silver chloride, or, at least, silver chloride, without the presence of any other reducible metal. Fortunately, this is a very easy matter, for we have only to substitute for the bleaching solution already mentioned one containing a soluble chloride and a little free chromic acid, or, what amounts to the same thing, a solution of bichromate of potash to which is added some common salt and a few drops of hydrochloric acid. When such a solution is used, the silver composing the image is converted into chloride, and beyond a deep yellow stain which pervades both the albumen film and the pores of the paper, caused by the bichromate, no other impurity remains. This stain is, however, easily and quickly removed by simple soaking in water if the print be kept from exposure to strong light, and the image may then be supposed to consist solely of chloride of silver, with the slight exception that will be referred to presently.

In speaking of the image, we have treated it as consisting solely of metallic silver, or some organic compound completely acted upon by the various bleaching solutions; but theoretically, in the case of a faded image, it should be composed, at least partially, of a sulphur compound of silver, to which it owes its yellowness. That the compound cannot be ordinary silver sulphide, or, if it is, that its quantity must be extremely minute, is evident from the behaviour of the bleaching solutions, for, while sulphide of silver is one of the most difficult substances to act upon, the yellow faded image is almost entirely removed by all of the solutions named above. The precise appearance of the print after bleaching will vary very materially with its condition before that operation, slightly in proportion to the degree of fading, but very considerably according to the original tone, that is to say, to the quantity of gold present. A vigorous purple-black toned print will leave, after conversion into chloride, an image of a greyish or slate colour which, after a very prolonged immersion in the chromic solution, almost disappears; the more fashionable red and brown-purple tones, carrying less gold, the image after bleaching is scarcely visible as a faint dirty yellow. That the substance forming the faded portion of the image is acted upon by the bleaching solution is shown by the fact that the very worst cases of fading exhibit scarcely, if any, difference in appearance after treatment from perfectly fresh prints of similar vigour. Therefore, we repeat, the image left by the chromic solution may be considered as practically pure chloride of silver, *plus* the very small quantity of gold added in toning.

But "faded" prints, in addition to the change of colour of the material forming the image, are usually marked by a distinct yellowing of the whites, which are frequently merged into the finer half-tones. The colouration of the whites, where, indeed, it is not mere yellowing of the paper from age, must arise from the results of carelessness in allowing traces of the fixing solution to remain in the prints, and such, as has over and over again been shown in these columns, contain sulphur compounds of silver. It would seem, therefore, that in treating in this way a print the whites of which are badly yellowed the only result of the "restoration" would be to convert the yellow colour into a decided deposit of silver of the same colour and character as the actual image, and consequently to considerably degrade the lights. Such an effect is often obtained when employing the mercurial or copper bleaching solution, but we have not found it occur when chromic acid is employed, from which we infer that that solution in some way removes or renders soluble the matter causing the colouration. Certain it is that mere discolouration of the paper, if not of too pronounced a character, is completely removed by the bleaching action of the free acid.

In fact, from a faded albumen photograph of the worst type the chromic solution, of which we shall give a formula, will remove every vestige of colouration except the scarcely visible traces of the image already spoken of, if the print be carefully and copiously washed after treatment. In this condition it only remains to select the most suitable reducing agent to reproduce the tone desired, and in making this selection it is well to bear in view the extent to which exposure to light is to be allowed to play its part.

By rapid development with a comparatively strong developer the same class of neutral black tones is obtained as with gelatino-bromide and chloride papers, while, by greatly diluting the reducing solution and exposing the bleached print to light more or less, an image is produced of the tawny-brown colour familiar with the old "Alpha" paper, and which is capable of being toned with gold to almost any colour.

It must be borne in mind that nothing but injury can accrue from exposing the print to strong light until the whole of the bichromate has been removed, because, while the chromic salt is liable to reduction, rendering the stain permanent, its presence entirely destroys the sensitiveness of the silver salt as such. Therefore, in taking advantage of the light's action, the exposure should only be made after the complete removal of the bichromate from the print.

Photo-mechanical Work.—In the Printing Trades Exhibition, which has been open for some little time, and closes to-morrow, at Islington, it is noteworthy that no special appliances in connexion with photo-mechanical printing are shown. There is not a single example of a hand collotype press, or a power machine, or a Woodbury press shown, although several Continental firms are represented. Neither are several other appliances which are made specialities of abroad shown, although they would have been interesting to English workers, and might have led to business. With the exception of a few collotypes and Woodburytypes, by one firm only, we think photo-mechanical work even is not represented. Possibly Continental manufacturers of the necessary appliances do not think the British trade in them worth cultivation, and few, if any, English makers have taken the matter in hand.

Collodio-chloride Paper.—Emulsion papers for direct printing now seem to be becoming the order of the day. Both collodio-chloride and gelatino-chloride papers were for a long time made on the Continent and imported into this country, but for some years their use was very restricted in England. It was not until one or two enterprising firms here took up the manufacture of gelatino-chloride paper that its employment became extended to its present proportions. Now collodio-chloride paper under different names is still being made abroad, and imported into this country; but, so far as we are aware, it is not made commercially here. It is quite probable that, if its manufacture were established here with the same enterprise—and for that matter by the same firms—as was the gelatino-chloride paper, it would be in considerable demand. The collodio-chloride process is a much older one than its rival, but its results are by no means inferior. We are in possession of some excellent prints that were made over twenty years ago. If we mistake not, the process has been in constant use by a well-known professional photographer in Scotland for about that period.

Varnish for Celluloid Negatives.—We are often asked for a formula for a varnish for negatives on celluloid films that will not attack the celluloid. Here is one that answers well in our hands:—White lac, or pale orange lac, four ounces; methylated spirit, eight ounces. When dissolved, add liquor ammoniæ, six ounces, and boiling water half a pint, and afterwards a drachm and a half of glycerine This solution may be filtered, or it may be allowed to stand and settle and the clearer portion decanted. It will generally have a somewhat opalescent or turbid appearance, but that may be disregarded, as it will not affect the negative. The mode of using is this:—After the negative has been fixed and washed, it is thoroughly drained. The varnish is then poured into a dish and the negative immersed and allowed to soak for a few minutes. It is then taken out and pinned by one corner to the edge of a shelf or other convenient article to dry. This varnish will also answer for negatives on glass, and it may be applied while the film is still moist; but, on the whole, for glass negatives a good spirit varnish is to be preferred.

The Compound Fixing and Toning Bath.—In our issue of last week appears an article from the *Beacon* with the somewhat startling heading, "The Alleged Fading of Silver Prints." In the article the writer makes a strong plea for the more general use of the old fixing and toning bath, as employed a few decades ago, which he says has unnecessarily been condemned as a system of sulphur toning. In doing so, however, he overlooks the fact that a recurrence to the old method is impracticable, at least under the present condition of things. To work under that system, we should have to entirely alter the character of our negatives, and make them like the intense ones of old. The paper must also be much more heavily salted, and have a far less albumenised surface than that now in vogue. Then, again, it would have to be sensitised on a bath of nearly double the strength of those in general use. Unless these conditions be fulfilled, the rich black and purple tones so frequently spoken of in connexion with old photographs are impossible. Let any one try the old system of toning with the modern highly albumenised, and weakly sensitised, paper, on prints from the present standard negative, and see the result. If we were to go back to the old conditions, then we should doubtless find that the modern system of toning and fixing would still give the most permanent results.

Reproduction of Photogravure Plates.—It is pretty generally known that many negatives, from which large numbers of copies are required for publication, are not printed from at all. A transparency is taken, and from it several other negatives are made. By this system printing is facilitated, and no risk is run with the original negative. A similar system is now being followed in some Continental establishments with photogravure plates. Although "steel facing" enables a large number of impressions all of equal quality to be obtained from a plate, and, when the steel facing wears through it can be easily removed and a new one substituted, so that, theoretically, the plate will last for ever, yet, when it is of a popular subject and a large number of impressions are known to be required, or they are wanted quickly, it is often reproduced. When the plate has been worked up by the engraver, and is finished ready for printing

from, an electrotype is taken from it, and from that any number of duplicate plates, all in every way equal to the original, can be made. Except for electrotype such a thing would be impossible. In connexion with this subject, it may be mentioned that the engraved plates of maps made at Southampton are never printed from except to make transfers for zincographic printing.

EXHIBITION OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The Exhibition of the Photographic Society of Great Britain was inaugurated on Saturday evening last, September 24, by a *conversazione*, at which the President (Captain W. de W. Abney, C.B., F.R.S.) and Mrs. Abney, assisted by the members of Council, received the invited guests. The attendance, which was thoroughly representative of all sections of photography, included Mr. J. Spiller (Vice-President) and the following members of Council:—Messrs. W. Ackland, G. L. Addenbrooke, W. Bedford, W. S. Bird, F. P. Cembrano, jun., W. E. Debenham, W. England, Colonel J. Gale, Dr. G. Lindsay Johnson, A. Mackie, J. Traill Taylor, Leon Warnerke, H. Chapman Jones, &c. Among the general company we noticed Miss Catharine Weed Barnes, Miss Carey, Miss Taylor, Mr. G. Mason (President elect of the Photographic Convention of the United Kingdom), Mrs. Mason, Mr. G. W. Webster, Mr. F. C. L. Wratten, Mr. Perigal, Mr. F. A. Bridge, Dr. J. J. Acworth, Mr. F. W. Hindley, Mr. T. P. Watson, Mr. W. H. Prestwich, Mr. W. J. Byrne, Mr. E. Clifton, Mr. H. E. Davis, Mr. Redmond Barrett, Mr. E. W. Foxlee, Mr. E. Ferrero, Mr. J. W. Marchant, Mr. H. Bedford Lemere, Mr. A. L. Adams, Mr. H. Smart, Mr. E. W. Parfitt, Mr. and Mrs. J. Hay Taylor, Mr. A. I. Taylor, Mr. T. Charters White, Mr. C. W. Gamble, Mr. A. W. Dollond, Mr. G. Houghton, Mr. T. E. Freshwater, Mr. R. P. Drage, Mr. P. Everitt, Mr. S. W. Rouch, Mr. S. T. Chang, Mr. E. J. Wall and Mrs. Wall, Mr. W. D. Welford, Mr. C. W. Hastings, Mr. T. C. Hepworth, Mr. T. Bolas, Mr. H. Snowden Ward, Mr. C. G. Norton, Mr. H. H. Griffin, Mr. Conrad Beck, Mr. H. R. Hume, Mr. J. A. Sinclair, Mr. G. W. Atkins, Mr. Frank Haes, Mr. N. A. Monnickendam, Mr. P. H. Newman, Mr. R. Child Bayly (the Assistant Secretary), and many others. During the evening considerably over four hundred guests responded to the Council's invitations, a number which is nearly a hundred in excess of last year's attendance.

The total number of exhibits is 693, being a decrease as compared with last year of fifteen. The falling off, however, is not in the pictures, but in the apparatus section. It may be of interest here to note that the 600 or so pictures actually hung represent only two-thirds of the number submitted, the gross total being, we believe, one of the largest ever sent in to the Society. The number of exhibitors is 202 (as against 185 last year) of which 64 are members of the Society. This calculation excludes several exhibits in the names of firms, the principals of which are in many cases members. Roughly speaking, the proportion of members to non-members among the exhibitors is about 1 to 3. Last year between seventy and eighty members were exhibitors. The Society, we believe, has a membership of over 400. For the exhibition of 1891 the Judges distributed eight medals, which, it was generally allowed at the time, were most wisely bestowed. This year, in a mysterious outburst of juridical generosity, no less than seventeen awards have been made.

Regarding the Exhibition as a whole, this somewhat lavish distribution of medals points directly to the inference, on the judges' part at any rate, that the average of quality, as compared with former years, is very high. In this view, we ourselves are inclined to participate, while we congratulate the Hanging Committee, who have placed little or nothing on the walls that the most fastidious critic could carp at, The Exhibition strikes us as particularly strong in landscape work. notwithstanding the absence of such men as J. P. Gibson, Horsley Hinton, Wellington, Ralph Robinson, and others. In portraiture we have seen few better displays. *Genre* and composition pictures are few and effective; the photo-mechanical exhibits are remarkably fine; the scientific subjects, though not numerous, are deeply interesting; but undoubtedly the strength of the Exhibition lies in its landscape work. It is not a one-picture Exhibition; so that "the picture of the year"—"the gem of the Exhibition"—is not obvious. Perhaps this fact, more than any other, will serve to emphasise the high average of excellence displayed. For the rest, the dominant tone of the pictures is a decidedly, and most agreeable, warm one, the reds and sepias giving more colour to the walls than we remember to have noticed before at a purely photographic exhibition.

The Medal Pictures.

Mr. Karl Gregor deservedly receives a medal for a series of five pastoral subjects, and a *Thames Sunset* (No. 5). The former are charming studies of sheep life; bright, crisp, perfectly lighted and exposed, and most carefully printed. In *Homeward* the flock is seen proceeding along a country road, and the realism of the picture is heightened by the cloud of dust above the sheep.

Mr. B. Gay Wilkinson also gains a medal for a series, of which *Westminster* (No. 50) is a silhouette-like view of the Houses of Parliament, taken from St. Thomas's Hospital, with the bridge just visible. He also sends (No. 48) *The Estuary of the Blyth*, (No. 49) *A Sunset Calm*, (No. 51) *The Peaceful Evening Hour*, (No. 52) *Where Tempests Beat and Billows Roar*, and (No. 53) *The Silver Strand*. In his twilight and sunset effects Mr. Wilkinson is very successful, No. 51 being most idyllic and poetical. *Westminster*, however, to our thinking, would have done with a little more detail. At present it is far too sombre in general effect. The series is printed on sepia-toned platinum paper.

It is a pity that Mr. W. Bedford should have chosen such unsuitable frames for his fine Norfolk series, Nos. 65–72, the contrast between the brown colour of the frames and the sepia tones of the carbon pictures being almost fatally narrow. Mr. Bedford is peculiarly happy in the management of his lights and reflections, the view of *Salhouse Dyke* (No. 67), the medal picture, being most successful in those respects. Alike in selection and treatment the series is a masterly one.

Colonel J. Gale's medal for a series is most justly earned. The rising mists of the *Incoming Tide* (No. 79) and *Towards Sundown* (No. 82) are very cleverly rendered, while a *Cottage Doorway* (No. 80), with a view of the interior, is a good example of a well-exposed picture. No. 85, *The Cornfield*, is one of those rustic subjects which this artist has for years made his own. An *East Country Quay* (No. 83), a delightful riverside study, in which the clouds are ably caught. In No. 81, *Flatford Bridge*, the handling of the water and the reflections are very clever. Colonel Gale has seldom sent better work to any exhibition.

Mr. A. R. Dresser receives a medal for (140), a softly printed view of Aylesford; but this is as well as Mr. Dresser's other two uranium-toned bromide pictures (No. 139), the *Meeting of the Conway and Lledr Rivers*, the turbulent waters of which are well suggested; and (No. 141), a stormy-looking *Evening*, are not free from several technical defects which surely should not have escaped the attention of the Judges.

As an example of successful child portraiture, in which the facial expressions of the small sitter are capitally expressed, Mr. H. Yeo's delicately printed series in platinum of *Blowing Bubbles* (No. 143) and *A Portrait* (No. 144) deserve the recognition they have gained. They are clever, unaffected, unforced little studies.

Mr. F. Muller's "*Portrait*" (No. 146) is a magisterial work, the wrinkles and locks of age, the bent head, the expression of venerable dignity on the face, being worthy of Herkomer at his best.

Worn Out (No. 184), by J. E. Austin, is a rich, warm-toned picture of an old fellow examining the works of a clock with critical interest. This and its companion picture (No. 185), the same subject surveying with consternation an *Account Rendered*, were both taken direct with a spectacle lens.

Mr. H. Stevens receives a medal for (No. 201) *Meadow Sweet*, a tenderly treated study. The same gentleman exhibits (No. 199) a forcible *Pack of Beagles*, and (No. 200) *Foxgloves*, (No. 202) *Coleus and Begonia* (a fine subject finely photographed) and (No. 203) *Addlestone Lodge in Winter*. The flower studies are in Mr. Stevens's best style.

Mrs. Main, in (No. 212) a series of six transcripts of Alpine *Frost and Sunshine*, repeats her success of last year. The gradations of the frost and snow in the clear Alpine light are well preserved, and, as examples of careful platinum printing, the series is very good. We must not omit to compliment this exhibitor upon her quiet but refined taste in mounting and framing.

Mr. J. Harold Roller is a prolific exhibitor this year, but shows nothing better or more clever than his frame of four *Direct Portraits taken in a Room*, for one of which a medal has been given him. This one—a lady seated in a large chair a little way back from a window—is perfect in lighting, modelling, and pose, while the remaining three, also similar studies, are remarkably fine. Mr. Roller gives evidence of being a most painstaking worker.

The carbon enlargement (No. 250)—*Break, break, break, at the Foot of thy Crags, O Sea*—for which Messrs. Elliott & Son receive a medal—is in many respects the most noticeable picture in the Exhibition. Its size is seven feet by five feet, and it is from a whole-plate negative by Mr. Birt Acres. It is, without doubt, a majestic work. From a placid sea the white crested waves tumble in upon ridges of ugly jagged rocks in the foreground, the seething, surging waters almost sounding in one's ears. The particular pigment employed adds to the fine effect of the study, which, in addition to its artistic value, is a splendid specimen of carbon work. It should, however, have been hung higher.

Mr. F. Boissonnas sends a large view of *Mont Blanc* at a distance of fifty-six miles, "taken with a Dallemeyer telephoto lens, with an extension of camera of 60 inches, 7 minutes' exposure, at 6.15 on the 27th of August, in windy weather, with an orthochromatic plate, and a yellow screen." Even allowing for the most favourable circumstances, this is a wonderfully fine picture, the definition and gradation being unexceptionally good. Accompanying the pictures are three very small views, giving the same view with an ordinary lens; another from Geneva with an ordinary lens (distant forty-four miles), and what the exhibitor calls a "conventional" print, with the mountain showing, such as is sold to "strangers" in Geneva.

The Autotype Company receive a medal for an autogravure reproduction of a painting of *Young England*, by Mr. Edwin Douglas, exhibited at the Royal Academy earlier in the year. This is a study of mares and foals, and those who saw the original at Burlington House will appreciate the excellence of the reproduction.

Turning now to the other exhibits, we notice that Mr. G. Lambert sends (No. 1) a good frame of three heads, taken direct with a single landscape lens. Mr. W. B. Smith's gold assaying (No. 2) is a creditable study, but the exhibitor should not have allowed the print to be stained. Mr. T. E. Freshwater's frame of *Bee Culture* (No. 3) contains a series of technically good photographs of direct interest to all those connected with bee-keeping. Mr. H. H. Cameron's portrait of Mr. G. F. Watts in his studio (No. 4) is perhaps rather hard in the lighting, while it is not difficult to trace in Mr. P. Ennis's pictures (No. 8) *Spring Time*, (No. 9) *The Path across the Common*, (No. 10) *A Reedy Mere*, and (No. 11) *The House by the Pond*, distinct traces of the influence of Mr. F. P. Cembrano's method. In No. 9, however, an attempt at impressionistic effect by means of fuzziness is not successful, but the other pictures are excellently composed and defined, and all are well printed on gelatino-chloride paper. *Carlisle Cathedral* (No. 12) on collodio-chloride paper, by Mr. J. B. Scott, is an accurately exposed interior, and Mr. C. Knight's *Hurdle Races and Steeplechases* (No. 13) are passable examples of a style of photography to which this exhibitor has for some time paid special attention. The Vienna photographer, Mr. J. S. Bergheim, sends seven figure studies and portraits (Nos. 18-24), which betray considerable artistic ambition. The study of a head (No. 17) errs on the side of softness, while the portrait of a lady (No. 21) proceeds to the other extreme. In their portrait of a lady (No. 25) Messrs. J. Chaffin & Son show a well-lighted, carefully posed study, and in *His Last Departure* (No. 28) Mr. R. Murray Lawes (whom we are glad to note among the exhibitors) a loftily placed but pathetic representation of the *Northumberland* flying the flag of Sir W. Hewitt, V.C. (who died a week after the ship's arrival at Spithead), and the *Sultan* (Captain Rice) leaving Vigo, March, 1888. Mr. F. Boissonnas gives in a *Sunset Study* (No. 30), a colour correct translation of the subject. This brings us next to a series of twelve small portraits of well-known artists and society people by Mr. F. Hollyer (one of the Judges) which are exceedingly happy in the poses selected. In (No. 47)

"Lions at the Zoological Gardens,"

by Mr. A. H. Benham, the highest praise we can give is that they vividly recall Mr. T. J. Dixon's *Lions*, shown so far back as 1879. The blue undertone of *A Devonshire Meadow* (No. 56), by Mr. J. G. Sinclair, is a characteristic drawback of many gelatino-chloride prints; and as for Mr. A. J. Golding's *Eventide* (No. 58), on the same description of surface, it errs on the side of a yellow colour. Mr. J. B. Scott will forgive us for pointing out that the charmingly posed lady in a *Reverie* (No. 59), is not in a reverie at all, but is looking straight out of the picture in the blandest possible manner. Mr. F. Thurston's outdoor portrait studies (Nos. 60–62) of the Earl and Countess of Albemarle and the Ladies Keppel are most praiseworthy in their unconventionality. In *A Calm Evening* (Nos. 86 and 87), Mr. G. W. Ramsay shows the difference produced by printing from the same negative on gelatino-chloride and on rough drawing paper, and an instructive object lesson in the relative amount of detail so obtained is the result. Mr. C. E. Corke's frame of six interiors (No. 90) are irreproachable, but Mr. E. H. Humphry's enlarged (bromide) view of the *Fort at Funchal* (No. 94) is flat and unpicturesque, while the lurid tone of Mr. J. E. Austin's landscape, *Pathways of Light* (No. 95), taken direct with a spectacle lens, somewhat transcends, we fear, a really natural effect. In

"A Rocket to the Rescue" (No. 96),

the picture of a rocket in its flight towards a doomed ship, with figures on the beach and a lowering sky, Mr. E. H. Godbold has accomplished a photographic *tour de force*, but little else. Mr. J. Carpenter's vase of *Cypripediums* (No. 98) is very correctly and cleverly translated. *Crossing the Brook* (No. 99), by Mr. H. Young, bears symptoms of halation. Mr. A. J. West's *Group of Children* (No. 101) is a pretty and reposeful study of young people; but in *A Haven of Rest* (No. 106), a platinum-toned silver print of fishing vessels in harbour, Mr. J. A. Hodges is scarcely so successful as heretofore. We have known this exhibitor treat similar subjects with far more poetic effect. A similar remark applies to the four exhibits of Mr. F. P. Cembrano, whose work is not by any means equal to that which he showed last year. Mr. W. D. Howard in (No. 115) *A Sunset on the Upper Rhine* and (No. 128) *The Boden Sea* is successful in reproducing clouds, sea, and sunset effects of a more subdued kind than those which largely prevail in the present Exhibition, and Mr. W. Illingworth's large direct portrait of *A Merry Belle* (No. 116) is capital in its natural and unforced charm. Good if not abnormally startling work is hereabouts shown by the Rev. E. S. Palmer (No. 118), *Skittles:* W. H. Banks (No. 121), *Skating:* A. W. Gottleib (No. 122), a thoughtful *Evening on the Severn* (on Alpha paper); and Mr. W. R. Cassel's two (Nos. 126 and 131) aspirations after *Land where the Olive Grows*. We like very much the small

Cat Pictures

of Mr. E. S. Dashwood, a frame of really humorous minute studies of the subterfuges of a knowing little cat to arrive at the contents of a milk-jug, in which the final picture shows him (or her) to be successful. These tiny pictures inevitably suggest Mr. C. Burton Barber. Mr. G. W. Ramsay's *On the Thames* (No. 133), *The After-Glow* (No. 134), *Springtime* (No. 135), and *Sunset* (No. 136), are good in intention, but their nebulosity proves that photography, by means of diffused treatment, cannot always be attempted with a certainty of arriving at the effects sought after.

In *Rubbish Burners* (No. 145), Mr. L. C. Bennett has well caught the effect of the smoke, but in the red-toned print (No. 183) of ships *In the Pool* the same exhibitor has represented the hulls of the ships too heavily, otherwise the picture is excellent. While little fault can be found with Mr. Harry Tolley's exhibits (No. 14) *Limestone Rocks in Derbyshire*, (No. 179) *Out of the Marsh a Fir-tree Grew*, (No. 377) *Christmas Time*, 1891, and (No. 379) *Calder Abbey*, they are not as imaginative as his work generally is. *Out of the Marsh a Fir-tree Grew* is, perhaps, the best of the series. Uranium toning is very popular this year, but it shows somewhat unequally in (No. 149) *Out into the West as the Sun went Down*, by Mr. A. V. Lloyd Jones, a picture which also strikes us as having an excess of foreground. Mr. Birt Acres' frame of *Hand-Camera Studies at Barnet Fair* (No. 152) are fair examples of this class of work; but the same gentleman's

"Study of a Cloud"

(No. 162), a series of five carbon prints, tracing the growth and changes of a bank of cumulus clouds, are distinctly clever as photo-

graphs, and interesting as scientific studies. Mr. A. W. Clayden should certainly see them. Mr. Acres also shows (No. 249) an enlarged study of *Scotch Cattle*, in carbon, and another frame of *Clouds* (No. 389).

Mr. W. J. Byrne is, as usual, a large exhibitor. A direct *Study* (No. 89), *J. G. Fleet, Esq.* (No. 151), *A Grecian Girl* (No. 174), *A Rehearsal* (No. 343), and *Little Bo-Peep* (No. 356), are quite equal in merit to the best of the large work he has previously shown, and his *Cabinet and Panel Studies of Children* (Nos. 278 and 314), show that he is successful as ever in juvenile portraiture. Mr. Byrne's little sitters always look as if they were quite at home under the ordeal of being photographed. In *A Trained Nurse* (No. 150), Mr. Henry Stevens depicts his well-known terrier nursing a sick cat, and in No. 173 the same two animals are comfortably asleep together. Mr. Henry Little's enlarged bromide interiors of (No. 155) *The Vatican Library*, (No. 344) *St. Peter's at Rome*, and (No. 357) *St. Mark's at Venice*, are capital in *technique*, although the latter would have done with a little more contrast. Messrs. Werner's skill in large portraiture is well exemplified in (No. 156) *Herr Snellen*, and (No. 232) *The Hon. Miss Wolseley*, but (No. 166) *Lady Henry Fitzgerald* is slightly hard. In addition to the one already noticed, Mr. J. B. Scott, of Carlisle, has several other frames of very good large portraits, of which we like the very soft and pleasing *Maiden with the Meek Brown Eyes* (No. 380).

Instantaneous Photography

is chiefly in the hands of Mr. Francis Blake. Years ago his pictures would have caused great comment; to-day, we fear, they will excite little interest. Nevertheless, they are undoubtedly clever. He shows (No. 158) *Pigeons in Flight, A Boy on a Bicycle, Engine of New York Express;* (No. 168) *Cow Pony* (in three positions) at sharp canter, and a series of tennis players (Nos. 424, 430, and 438) in various positions. Mr. R. Slingsby's examples of continuous magnesium light photography (Nos. 169, 291, 293) show the excellent adaptability of this illuminant to portraiture. Messrs. Mowll & Morrison (Liverpool), C. F. Treble (Clapham), Messrs. Window & Grove, Gabell & Co., E. Spencer, are all well represented in large portrait work, the task of separating them in point of merit being a difficult, if not impossible, one; while, in addition to the pictures for which they have taken medals, Mr. H. Yeo and Mr. F. Muller are also numerously represented by other frames of portrait studies printed in various styles. Mr. F. Muller's work is full of character.

We shall probably not be going wide of the mark in conjecturing that with (No. 170) *How's That?* Mr. R. H. Lord only just missed a medal. It is a large, sepia-coloured, platinum picture of two old gentlemen exchanging confidences over a pinch of snuff, freely handled and skilfully treated. In (No. 175) *An Idle Moment* and (No. 176) *The Ripened Grain* it is no drawback to Mrs. Tillyer to say that her work is decidedly suggestive of Mr. Gale's method; and the same remark applies to Mr. E. H. Hazell's *Old Stager* (No. 177). In (No. 186) *Gentle Janet*, the portrait of a small child by a window, Mr. P. B. Broomhall has not lighted the shadow side so well as he might have done. Miss Egerton's portraits of the Archbishop of York (No. 338) and (No. 364) the late Sir F. H. Doyle have a pleasing, engraving-like character, and are otherwise commendable. Her print of *Paderewski* (No. 188) is not a good one. Mr. A. R. Dresser's uranium-toned *Watching the Waves* (No. 189), *"Skylark" Landing* (No. 190), and *Storm at Hastings* are equal to his medalled work, but the toning process appears to be at fault. Mr. Adam Diston's small, carefully printed interior of

"The Rehearsal"

(No. 194) is quietly humorous. An old lady has fallen asleep, while the musician (possibly her son) is laboriously puffing at his instrument. Mr. G. Renwick has four frames of frost studies of undoubted excellence, but their position, so near to Mr. Stevens's and Mrs. Main's work of a similar nature, rather kills them. Mr. J. E. Austin's spectacle-lens picture of *A Son of the Soil* is too spruce a young agriculturalist to be picturesque, and Miss F. Browne's large portrait of *Mrs. Jack Johnson* (No. 211) suffers, we think, from not enough light being on the letters (the lady is supposed to be writing). Why is there more light on the face than on the writing-table? The lady in Mr. A. Burchett's refined picture (No. 206) of *The Love Letter*, who is smilingly holding that interesting document, has a ring on her third finger, which in our experience unmarried single ladies who receive love-letters do not wear. Perhaps, however, Mr. Burchett knows better. The picture is in this gentleman's best style.

In No. 217, Mr. E. Lambert has five other studies of heads taken with a single landscape lens. Mr. Kemp's *First Love* (No. 222) is a venerable and wrinkled old dame. Mr. D. Pym's large direct portrait of *Mr. Herbert Sims Reeves* is faultless, save in respect of being too sharply vignetted off. Mr. Seymour Conway's work in (No. 221) *Silver Birches, Borrowdale*, and (No. 230) *Evening Derwentwater*, is full of his former charm and delicacy of treatment, but we fear the new-fangled fads of the impressionist in photography overshadow this and many more examples of good pure photography. Mr. W. Wainwright's *Alpine Views* are also excellent; and another old supporter of the Society, Mr. T. M. Brownrigg, is to the fore with *Portinscale Bridge, Keswick* (No. 234), in which, however, while the water and the reflections are ably treated, the distance appears to us to be too flat and uniform. Mr. G. Lamley's *Sluggish River* (No. 239) is a well-chosen bit neatly photographed, and the same gentleman is also represented elsewhere by various other clever little landscape studies. By the way, has not one of these, *Blowing up for Rain* (No. 470), been "exhibited in London" before?

The cattle in Mr. J. Kidson Taylor's pleasing little *Evening* (No. 246) are well disposed, and Mr. W. A. Rouch's *Snap-shots* (No. 253) are clever of their kind. We certainly anticipated a far greater number of hand camera pictures than are here. The tones of the Rev. J. A. Rivington's three pictures are novel but not agreeable; nevertheless, (No. 258) the figure of a lady *Outside my Window*, is

A good Specimen of Outdoor Portraiture,

both in posing and lighting. Mr. E. D. Stern's *Eastern Scraps* (No. 255) are interesting from a topographical point of view, and, in Nos. 261–5, Mr. H. W. Bennett has a series of marine studies which show considerable skill in this class of work. In (No. 269) *Sunset over Bergen Harbour*, Mr. E. H. Fitch, from a negative by Mr. Paul Lange, has introduced a fine cloud effect, and the last-named gentleman's *Street Scene, Molde* (No. 447), though small, is perhaps as perfect an example of crisp definition as the Exhibition contains. Such definition should have been present in Mr. G. W. Tyser's *Venetian Views* (No. 270), for which the printing process selected is not quite suitable. Mr. T. M. Browrigg's *Studies on the Wey and at Derwentwater* (Nos. 274–5 & 282-4) are excessively soft. As an example of realistic photography Mr. A. W. Gottleib's *Study of Grapes* (No. 279) deserves notice, and Mr. H. Bedford Lemere's views in the mansion and grounds of Mr. A. de Rothschild are equally worthy of mention. In Nos. 289 and 290, Mr. E. H. Hazel shows that he has acquired great skill in animal photography, the dog and cat being very good. We should have been better pleased with Mr. W. Scorer's otherwise fine large views of *Netley* (No. 285) and *Portsmouth Town Hall* (No. 303) if they had formed the subjects of more vigorous prints. Mr. E. F. im Thurn, of British Guiana, sends a collection of ethnological studies of that region, and Mr. E. D. Stern's *Scenes in North Africa*, like the foregoing, if of little photographic account, make the same appeal to notice. Mr. W. Thomas sends three frames containing eighteen small quarter-plate pictures chiefly of seaside work, which contain much in little, and that of a really clever description. There was a time when small work was much despised; but these and other pictures in the present Exhibition show how most effective photographs may be made on a small scale as well as on a large one.

Herr Bergheim's *Miriam* (No. 324), a study of an Eastern beauty, is a fine, bold work which we much prefer to the somewhat too highly diffused portrait by the same photographer to which we have already adverted. Most of the successful portrait work in the present Exhibition is, on the whole, thoroughly well defined—a fact which in no sense detracts from its artistic value. There are some finely modelled cattle in Mr. H. Sandland's large carbon picture of *The Homestead*, but otherwise it is commonplace, if photographically irreproachable.

Some Interiors.

In Nos. 345 and 358, Mr. F. H. Evans shows several "interiors" of Ely Cathedral, excellently selected and exposed, and charmingly printed on sepia platinum paper, and Mr. Evans' work is, without

doubt, unexcelled in this particular department. Other examples of cathedral work are shown by Mr. J. H. Avery (Canterbury and St. Albans); Mr. J. H. Gear, C. Court Cole (Exeter); T. H. Morton; and Mr. Richard Keene (Dunfermline), all of which are, without exception, excellent. Lieutenant Cottingham's large picture of the *Yacht Diamond* (No. 369), suffers, like many other pictures in the present Exhibition, from the same thing having been, as it were, done to death some time ago; this, however, does not detract from its excellence. Of *Worn Out* (No. 370), by Mr. F. Whaley, the labour involved in its production almost precludes us from saying that it is disappointing in effect. A father has fallen asleep by the bedside of a presumably sick boy; but the lad appears to be in excellent health, and the father seems to be tired of reading the paper. There is nothing except a belated medicine bottle on the table to indicate that the boy is ill, and the whole picture utterly fails in effect. Mr. Whaley must try again.

Pictures on the Screens.

On the screens we note examples of J. B. Obernetter's landscape work (Nos. 440-5), which do the paper of that name every justice; and further small portrait work of Mr. F. Muller. *A Summer's Day* (No. 458) is a delightful study of cattle in water; while the clouds of *On the Upper St. John's*, by Mr. C. B. Moore, are highly effective. *Come here, you rascal* (No. 466), an old lady beckoning a nude child in a corner who has escaped her clutches is amusing enough to provoke more than a passing smile. Mr. Gear might cultivate this vein to advantage. In Nos. 475-6, Mr. Whitworth Wallis has some wave studies full of life and movement; and Mr. A. D. Halford some well-rendered cattle in *Dedham Bridge* (No. 490). The picture would, however, have been improved by a cloud. Mr. J. E. Dumont is represented by eight pictures, some of which are highly diverting studies of monks. One of them (No. 490), *To-morrow will be Friday*, is familiar to the public. Some of Mr. E. Detmold's cattle pictures are clever, one of them in an enlarged state hangs in another part of the room. Mr. A. G. Tagliaferro in *An Uninvited Guest* (No. 526), and *How happy could I be with either* (No. 538), has more than equalled all his former efforts, and is to be commiserated on having been so badly hung. In the former picture an impudent bird is boldly walking off with a portion of a dinner to the concern of the diner, while in the latter two attractive young girls are smiling and whispering aside, as a jolly old fellow surveys them out of the corners of his eyes with an expression of face such as is implied in the picture. In composition and treatment the pictures are indisputably the work of an able photographer.

In portfolios there are unframed pictures by Messrs. J. C. Douglas, J. B. Obernetter, J. H. Tasbell, John Catto, R. E. M. Bain, B. Kimball, the Prince of Travancore and others, many of which are excellent; and among the other exhibitors are Messrs. C. P. Castine, A. L. Spiller, E. C. Fincham, J. G. Sinclair, Rev. E. S. Palmer, J. C. Douglas, M. J. Harding (who shows richly toned work in Soltype), Harold Baker (capital portrait studies), F. Downer, W. Street, E. Spencer, S. Bourne (a most industrious and successful veteran worker), Rev. H. B. Hare, Edgar Scamell (with a series of *Street Cries*), H. L. Sworder, W. T. Goodbew, L. Selby, J. B. Hilditch, S. R. Brewerton (whose *Sheep Shearing* is very clever), Underwood French, G. A. Nelson, H. G. Moberley; and many others.

Photomechanical Pictures.

Carbon work, as we have elsewhere remarked, occupies a gratifying prominence in the present display among the general exhibitors, and both the Autotype Company and the Woodbury Company show largely in this and the photo-mechanical classes respectively. The former Company, in addition to the medal reproduction of *Young England*, show autotype enlargements, studies in red chalk, portrait studies on lined etching paper; an autotype reproduction of W. L. Wyllie's forcible drawing of the White Star liner, *The Majestic;* an autogravure reproduction of Lance's *Christ in the Carpenter's Shop:* and a sepia portrait study on opal. It need scarcely be said that these varied exhibits indicate the remarkable excellence of this Company's work as fully as ever.

The Woodbury Company are represented by numerous well-executed carbon enlargements, as well as by a frame of charming examples of Woodburygravure; Messrs. Thevoz & Co. (Nos. 385, 427, 433), J. R. Gotz by examples of phototypes of the delicate quality for which the firm is renowned; Messrs. Boussod, Valadon, & Co. (Nos. 388, 395, 400, 405, 410–13, 425, 428) have a varied collection of Goupilgravures, photogravures printed in colours, of well-known paintings, exhibiting the world-famous productions of this house to perfection. Mr. J. B. Obernetter's photogravures (Nos. 422, 423, 431) are charmingly soft and dreamy in quality. Mr. R. Frost's photographs of machinery (Nos. 393, 406–8) are specimens well illustrating the utilitarian adaptations of photography; and Mr. E. S. Shepherd's photogravures (Nos. 390, 391) bear comparison with the best of the fine work among which his is placed. Other exhibitors in the department of reproduction are Mr. J. H. Roller, Mr. C. E. Corke (with a good copy of a water-colour painting), Mr. A. Guye, jun., shows (No. 396) some admirable enamel work, and Messrs. Forrest (No. 403) a large portrait of Mr. J. Hauff, the negative and bromide enlargement being developed with amidol. Mr. C. Coles' windows (Nos. 414–17) on Solio paper are examples of well-exposed pictures.

In the department of scientific photography, Mr. C. W. Gamble is represented by a history of Dentition (No. 426), showing the development of temporary and permanent teeth; Mr. T. Charters White by (No. 429) photo-micrographs of anatomical subjects; and Sir H. E. Roscoe and Mr. J. Lunt by (No. 432) photo-micrographs of pure cultivation of bacteria from sewage.

The Apparatus.

The display of apparatus is not particularly large, although it contains several novelties, most of which, however, have recently been noticed in our columns. The apparatus was explained at the Technical Meeting of the Society in the Gallery on Tuesday night, and such descriptions of novelties as we have not already given appear in our report. The exhibits include specimens of Carlotype printing-out paper, cards being sensitised, and requiring neither mounting nor toning, the results much resembling kallitype; excellent film negatives, and negatives on photo-mechanical plates, shown by Mr. J. D. England, as well as the same firm's neat and effective film-carriers with aluminium ends. Messrs. W. Watson & Sons new studio camera stand and other examples of this firm's excellent photographic cabinet work, including the "Acme" camera, all the metal work of which is in aluminium, thus considerably reducing the weight; "Nameit" for producing titles on prints; Mr. W. Sanders' opera, marine, and field-glass camera, with metal roller slide; the Dresser hand camera (H. Crouch); an adjustable vignetting attachment for printing frames (J. H. Smith); a beautiful "wide-angle" camera by Morley & Cooper; Messrs. Smith & Sons' new plate washer; a self-adjusting tripod head (Mr. W. Goode); stands fitted with Elmers' patent levelling head (Newton & Co.); varied exhibits by Messrs. J. R. Gotz; Houghton & Son; Adams & Co.; Messrs. R. & J. Beck; the Ideal optical lantern (Archer & Sons); a case of lenses by Messrs. Swift & Sons; and the standard system of fittings for the attachment of lenses to cameras, for which Messrs. Taylor, Taylor, & Hobson have received a medal. This system was fully described in a recent number of the Journal: while, as already said, those novelties in apparatus not noticed in this brief survey of the exhibits will be found treated of in our report (see p. 636).

The Lantern Slides.

Only ten sets of lantern slides were sent in for competition, Mr. E. G. Lee, of Newcastle, taking a medal for a clever series taken by means of a hand camera. Mr. T. E. Freshwater shows slides of *Bee Culture;* Mr. G. Hankins a miscellaneous collection with a great variety of tone, while, in Mr. J. Dore's three sets of landscapes and animals, lifeboat practice, and clouds and sea, not only are the tones most admirably managed and varied, but the slides are beautifully bright and clear. Mr. Dresser's slides of the *Wild West Show* are brilliant and animated studies; Mr. Carpenter's flower subjects are as carefully rendered as his prints of similar subjects; Mr. A. J. West is entirely successful with his yachts and ships both artistically and technically. Messrs. J. D. England, H. Sandland (animals), and A. Brooks also show excellent exhibits in this section.

In taking leave, for the present, of the Exhibition, we must not omit to acknowledge our indebtedness to the courtesy of Mr. R. Child Bayley, the assistant secretary, who has been most assiduous in affording information to the representatives of the press.

PHOTOGRAPHIC LIMITS.

[London and Provincial Photographic Association.]

When so much is being said as to the true status of photography, what it can and cannot do, what it ought and ought not to do, I feel that a survey of the subject and the criticisms upon it might be made with profit. Save me from my friends, to say nothing of my enemies, might Photography well cry; for it is blamed, on the one hand, for its extreme accuracy, and, on the other, for not being accurate enough. The fact that such a question can be asked as, "Can photography lie?" and a serious answer be expected, shows the exceedingly great misapprehension existing as to photographic limits. Why not ask, "Can a painter's brush lie?" It does that same thing many a time and oft. While journeying this summer, I saw a painter busy on a certain view, and, though his drawing was reasonably good, his colouring almost blinded me. A well-taken photograph would have been vastly preferable. In this connexion I cannot but fear that, when those earnest workers who are trying to solve the photography-in-colours problem attain their end, they are going to be somewhat disappointed. Colour may be obtained, but not atmosphere; and to an artist that means a great deal. The most ardent camera devotee must own that the scope of his beloved instrument is limited; but he has a right to demand those limits shall not be arbitrarily circumscribed, or that photography shall be looked upon only as the poor relation of painting. Photography suffers because it is ordered to confine itself, outside of pure portraiture, to scientific work mainly, and is told it should not trench on the artistic preserves. The camerist is fully justified, and the claim cannot be too often or too strongly made, in drawing on all the resources of both science and art to realise his mental conceptions. As painters use different brushes for different kinds of work, so the camerist uses different lenses. What may be a positive defect in a lens when used for one branch of camera work proves often a virtue for another, and the artist is shown when the worker has skill and taste enough to reconcile the lens to the object sought. This means endless experiments, disappointments, exercising the most patient judgment, and, in short, attempting to adjust the too-often conflicting claims of art and science in the photographic field. Although this is a broad and somewhat well-worn subject, there are still some things which can be said, and plainly said, upon it. Mr. Hinton's recent article, referring to work at exhibitions, should be widely and thoughtfully read, and its temperate tone gives it added importance. Exhibitions for the art side, pure and simple, have been held; but it should be suggested to the wise and good who preside at such exhibitions, or fill the post of judges, that art is sometimes confounded with liberality, and they are by no means one and the same thing.

Science and Photography.

Scientists labour to secure as nearly perfect instruments as possible, and then, if they do not possess the art instinct, are apt to quarrel with those who believe not alone in elucidating some great scientific fact, but in turning the keen eye of the lens on the beautiful as well as the useful, studying its possibilities with a loving reverence until the senseless instrument seems to enshrine a living soul. I do not see any need for perpetually erecting this barrier, nor why those who keenly enjoy every new discovery in the pure science of photography should not also realise what great power it gives in developing the art side. The wonderful achievements of photographic science in the constantly expanding fields of human thought have, to some extent, bewildered people's eyes, and affected their judgment. In its vastly increased facilities for work, photography is in danger of growing very much to one side, and that the scientific, unless the art fanatics, as some critics consider them, bring on such a thunderstorm occasionally as shall clear the controversial air, and allow photography to show what is possible in the way of broad, healthy growth. Why is it that, if we are so willing to acknowledge the tremendous strides made in strictly scientific knowledge, thanks to the lens, we are reluctant to acknowledge its power in the art world? Partly because photographers themselves as a body are not yet able to realise that the work is more than a pastime or a means of wage-earning, that, if they expect people to respect photography, they must prove its indubitable right to respect and give it constant and faithful study. Hundreds of photographers are not fit for their business, and very few, I am afraid, follow the custom of a distinguished Frenchman, and, out of working hours, study daily the effect of varied lighting on two figures, one draped in white, and one in black. How many understand the importance of the quality and thickness of thin skylight glass as affecting the limits of photography? Artificial lights, such as electricity or flash light, are good in their way, but are worse than useless in unskilful hands, justifying the reproach that photography is attempting too much. There is great room for extending photographic limits in the studio if operators would be liberal-minded enough to open their eyes and cultivate their understandings. This means educating the public, as well as the profession, and might rule out a large proportion of the latter; but that would be no loss, and the profession, as a whole, would gain immensely in the respect of men. Of course a pint pot is not to be blamed for being such, but it should not attempt to hold the ocean.

A story told of Douglas Jerrold may illustrate this point. Once an utterly incompetent author attempted to justify some of his poor work to the witty critic by the plea, "A man must live, you know!" "I don't see any necessity for it," said Jerrold. Many advanced photographers are, it should be said, ready to welcome new ideas, but are held back by the consideration that great changes involve at first increased expense, and sitters fail to appreciate that fact. Perhaps in no one branch of human knowledge have as great and varied improvements been made the past few years as in photography; but in some ways, while its limits have been extended, the work has suffered thereby. People are apt to imagine not that real progress has been made, but that the trick has been more cleverly managed, so that in one sense the work was more honoured when it cost more time and labour than now, when a vast world of appliances have made it easier. We do appreciate a thing more when we have to work for it.

The Value of Previous Training in Drawing and Painting.

While in England, nothing has impressed me more than the care given, on the whole, to making an exposure, guarding the plates from unsafe light, and, in fact, taking pains to do all the work well. It has been my privilege to work with some of the best-known English photographers, and to learn many lessons thereby. I think in this connexion that previous training in drawing and painting should be valuable as giving freedom from the usual cut-and-dried recognised methods in camera work. Neither microscopic definition nor indiscriminate fuzziness, neither hand cameras nor tripods, is the only true and to be accepted doctrine for camerists, but each subject should be studied as a painter studies his subject, and treated as will show it to the best advantage. If this means obliterating any part of the negative or print, it should be done without the slightest apology. In short, from the moment of taking the plate from the box to mounting the finished print, consider, and only consider, the effect you wish to obtain. There is a certain class of critics who say photographers have no call to attempt purely illustrative work, it is beyond their province, and they wax eloquent on those unfortunates who essay the *rôle* of original designers and translators of poetic ideas into visible pictures. There are, to be sure, poems utterly unfitted for photographic reproduction; but there are many, very many, others which could well be illustrated by the lens, and the results utilised in some of the beautiful processes now possible, so that the reproductions would deceive the very elect as to their origin. The fact that it is in our power in these days to use lenses of such widely differing power is vastly more than adding to a painter's stock of brushes, and he who seeks to do really artistic work must have a battery of them, take the time to consider which one will be best for the view desired. Many workers use a lens altogether too large for the plate, which is almost as bad as straining a lens beyond its capacity. The difficulty of using different lenses in one front board seems likely to be met by the adjustable flanges now on the market. Like every other part of the apparatus, the lenses should be easily and quickly adjusted, and every one have a cap for one end as well as the other.

Landscape Work and Development.

Regarding landscape work, the matter of limits is simple, to define interiors far more so, and figures most difficult of all. But it seems to me, that if a figure study tells without explanation the story it is intended to tell, the designer can well afford to be utterly indifferent to all derogatory remarks as to whether his picture is or is not what certain grumblers would call "just a photograph." One of the leading art critics of New York was showing me some photographs a while ago which I said were poor, but which he intended to reproduce in a well-known magazine. "You look at them," he said, finally in a very positive tone, "merely as a photographer. I look at them as an artist." "Pardon me," was my reply, "I have been a photographer a very few years and up to that time worked in painters' studios."

When the camerist comes to the developing stage, the Scriptural injunction should be adopted of proving all things, and holding fast to that which is good. The danger, however, is that the more expert a worker becomes the farther he is tempted to stray from the path of true art, simplicity, studying not merely the most fitting medium for showing his work, but making it a means of exhibiting his purely technical proficiency. There should be far more attention paid to development, and no one but the operator should by rights develop the exposed plate. Then, too, comes up the question of what is hand-camera work. At a recent Society meeting it was agreed that, if a

bonâ fide hand camera was placed on a tripod, its results were not really hand work. Considerable discussion took place, but it would seem as if we miss the real value of the work itself by raising such nice distinctions.

Relations between Professionals and Amateurs.

And now there is one more point which suggests itself, and that is, the true relations between professionals and amateurs. There should be no jealousy between the two detachments of the camera army, as both seek a common end, and can best attain it by united action. I do not believe in drawing a sharp line of demarcation, remembering what I personally owe as an amateur to professional advice and criticism. It has been my fortune to be thrown into close relations with the profession at several conventions and exhibitions in America, and have, despite occasional illiberality, received from the best part of the members only cordial kindness and respect. We can help each other and frankly own that fact.

In closing, let me say that this question of photographic limits is, after all, largely a matter of each worker's taste and skill. From the most careful scientific analysis to the most artistic conceptions, the lens obeys the will of the brain, using it far more broadly than some are willing to believe. The subject is one which could be followed into many bypaths and is too great for one evening's discussion. Let me put in a plea for fair judgment, a welcome for everything which will aid photographic progress in any and every field of human endeavour, and a reminder that such progress will be best attained by ignoring the point whether this or that branch of the work will be most benefited by each new discovery, remembering that advancement in one means advancement in all. Working on broad lines, keeping brain, eyes, and ears receptive and liberal, we will in time place photography in her true position before the world. Let her limits continually expand, and each and all lend a hand in the good work.

Catharine Weed Barnes.

DECORATIONS AND FITTINGS.*

The decorations of the room itself should be delicate, chaste, and neutral in tint, relieved with gold or pale colours, which act as a foil to any pictures that may be exhibited. The idea is to have surroundings that, without being sad or assertive, should set off the contents of the room to the best advantage. A very light and pretty style is the Moorish scheme of ornamentation, with pale green for the predominating tint, and fretwork painted of the same colour, all bright, pronounced colours being avoided except in very minute quantities. Any small window, the light from which is not important, may be glazed with stained glass often with a very pretty effect.

The furniture, plain and good, with chairs and lounges, comfortable and luxurious, works of art of various kinds, interspersed with handsome foliage plants, may be placed here and there with good effect. A moderately dark carpet is to be preferred, as it affords rest to the eyes, with a few richly coloured rugs laid here and there, and at least one large mirror fixed where lady visitors can see themselves from head to foot without trouble. The dominant idea in fitting the reception-room is to induce in the sitters a pleasant and satisfied frame of mind, and to remove as much as possible any feeling of impatience or dissatisfaction in having to wait some time before their turn comes to place themselves in the hands of the operator. A person irritated and impatient is in the worst possible condition for having a pleasing portrait taken, so it follows that every means should be adopted to interest and amuse. Some copies of good periodicals and illustrated literature, with a daily newspaper or two, will help to wile away the time.

The illumination of the reception-room should be fairly strong; if too subdued, the strong light of the studio is apt to cause a contraction of the pupils of the eyes, and make them look smaller than they really are. To persons with very sensitive or weak eyesight the strong studio light will often, under any circumstances, induce a frown that is difficult, if not impossible, to get quite rid of during the short time they remain in it, to the disadvantage of the portrait. Of course, this is intensified by having just beforehand stayed in a room in which the light is very subdued. The small panes of glass with which many studios are glazed, and the forest of sash bars necessitated, militate much against good expression, unless the light is filtered through waxed paper or its equivalent. The opinion of the late O. G. Rejlander was that the light on the sitter should fall with the least possible obstruction, and not a bar more than absolutely necessary should be used. The studio in which his most successful pictures were taken was lighted by two windows, each glazed with one pane of plate glass. A better authority it would be difficult to find.

With regard to the colour of the glass room, consensus of opinion is in favour of pale blue or grey, with little or no ornamentation. Of course, something depends on the space to be covered, but in a studio of the ordinary kind nothing is better than this. Sometimes dark chocolate or brown is used, but has the disadvantage of making the shadows too heavy, unless a very complete system of reflectors is used to counterbalance it; it has, besides, no compensating advantages whatever. The idea of it being restful to the eyes has, I believe, been proved fallacious; and, in addition, the exposures are considerably lengthened, especially if the studio is lighted only from one side and part of top.

With regard to the floor, few things are better than good linoleum to cover it with in the first place, on which may be laid small carpets or rugs that may be easily pulled aside as occasion requires. Handsome skin rugs are very useful as accessories, besides improving the appearance of the place. Foliage plants and ferns are both decorative and useful, and should find a place in every glass room. Well-grown plants afford unending variety as accessories, and almost supersede the use of furniture in picture compositions; at any rate, by their aid very much furniture can be dispensed with, and very indifferent upholstery work made to look well.

Backgrounds are important fittings, and, with the exception of large ones heavily mounted at the end of the studio, should be light and portable as possible, for in these days of fancy lighting they have to be continually moved about from place to place according to the effect desired. Unwieldy heavy backgrounds I look upon as unmitigated nuisances if they have to be shifted about much; there is always danger of upsetting them or something else, besides occupying a good deal of time that might be better spent. I think any operator working single-handed will bear me out in this opinion. Blinds can scarcely be looked upon from a decorative point of view, although they considerably influence the appearance of the place. The most useful are thick, soft, dark blue and ordinary white blinds, which should be kept clean and in order. Ragged, weather-stained blinds always give a disreputable look to a gallery. An additional large, blue gauze curtain is exceedingly useful in moderating the effects of a strong light without perceptibly slowing the exposure. Footstools of different heights are always in request, and are better than extemporising boxes, books, or anything that may come handy.

The dressing-room devoted to ladies should have bright, cheerful fittings, and the usual toilet appendages, not omitting a large cheval glass, which is always appreciated. Fresh-cut flowers set about in suitable receptacles give a homely, pleasant effect, and are always an improvement to any scheme of decoration. It goes without saying that the whole establishment should be kept as free from dust and dirt as possible. Slovenliness as an eccentricity has had its day, and the better order a place is kept in the more attractive it is.

Edward Dunmore.

* Concluded from page 615.

EXTRACTS FROM THE DAILY PRESS ON THE PHOTOGRAPHIC EXHIBITION.

[*Daily Chronicle.*]

A photographic Exhibition has better reason for its being than most exhibitions can boast. The few people who have gained distinction by not becoming amateurs in the art will most likely visit it out of curiosity; the others will go as a matter of course, as critics. And both classes will have their reward at the annual Exhibition of the Photographic Society of Great Britain. The cognoscenti who are learned in tones and lights and distances will there find all that is best in these things, and even the most hardened photographic Philistine will have cause to wonder and admire. To the latter, whose education in matters photographic has been got from the pictures of professional beauties in shop windows, and "views of Margate," the most startling thing will be the decadence of the silver-print. He will be surrounded by pictures done in "bromide," "platinum toned, Obernetter paper, "Carbon," "Gelatino-chloride," "Soltype toned with platinum," "uranium-toned bromide," and in many more bewildering ways, but his old familiar friend of the family portrait album will meet his glance but seldom, and even then will be in a glorified, refined condition. The silver-print, indeed, seems as much doomed to extinction as the primeval Daguerreotype, and it is cause for no regret, for the platinum or bromide process—besides being permanent—is susceptible of far more artistic treatment, and is certainly more restful to the eye than the best work done in silver.

Of the Exhibition itself it may be said that it is of greater merit than that of any previous year. The pictures shown are all of a high standard of excellence, and the task of the judges in awarding medals must have been one of no little difficulty. The work which will command most

attention, no less for its beauty than its size, is a carbon enlargement, exhibited by Messrs. Elliott and Son, from a negative by Mr. Birt Acres. The picture, which measures 7ft. by 5ft., is a fine study of the surf breaking upon a rockbound coast. A greenish tint has been given to it, which heightens the realism, and there is none of that blur which so often obtrudes itself upon photographic seascapes. Of landscape work there is an infinite variety. Mr. B. Gay Wilkinson gets a medal for a series of six studies, all of which are gems in their way; but the best of them, and perhaps the very best thing in the exhibition, is *The Peaceful Evening Hour*—a triumph of photography, which shows better than anything else can show of what the art is capable. Mr. Karl Greger exhibits some really beautiful studies in the same department, his *In the Welsh Mountains*—in very low tones—being a delicious bit of work. A singular fatuity in the matter of framing is shown by not a few of the exhibitors. For example, Mr. W. Bedford, who is awarded a medal for some splendid work in carbon, has altogether spoiled the general effect of his pictures by putting them in frames of the same colour as the prints—without even the relief of a white mounting; and again and again one comes across good things crammed into frames that are utterly unsuitable. Mrs. Main seems to have quite solved the difficulty of presenting snow in a photograph as snow, and not as a blank white heap of something which might be flour, or cotton wool, or anything but snow. Her snow is crisp and cold and natural, and she certainly deserves the medal that has been awarded to her. A remarkable and most interesting photograph is that of M. F. Boissonnas, representing Mont Blanc at a distance of fifty-six miles. It was taken with Dallmeyer's tele-photographic lens, and was the result of seven minutes' exposure on an August evening during windy weather. The detail is wonderful. The pictures of the mountain taken by an ordinary lens which are exhibited by its side conclusively show the advantages of Dallmeyer's lens for distant work. In the way of portraits there is nothing better in the exhibition than the head of an old man by Mr. F. Muller. It is the nearest approach to a fine old steel engraving that photography has yet produced, and is admirable in texture and colour alike. To an instrument that can make a picture of a flash of lightning and take the portrait of a bullet in full flight everything is possible, and the examples of instantaneous photography which the exhibition contains are not its least attractive part. The most charming, because the most spontaneous and happy, is *Where there's a will there's a way*, by Mr. E. S. Dashwood. These are four small views which tell the tale of a cat straying from the path of rectitude and stealing milk from a jug. The first shows Pussy making a bee line for the jug, the last exhibits her standing stiffly on three legs, while she licks the paw which has just been dipped into the milk. *Blowing Bubbles*, for which Mr. H. Yeo gets a medal, also tells a tale in a way in which only instantaneous photography could tell it. All the latest things in apparatus are here to be seen, and for any one who meditates entering upon a career of photography they would form a singularly complete outfit.

[*Daily News.*]

The annual Exhibition of the Photographic Society of Great Britain, is of considerable and varied interest, especially with regard to the landscape work, in which field there is every year a closer affinity between the photographer and the painter of pictures. There are not many special discoveries to record this time, but the level of artistic attainment is well maintained, and it is evident that the judges of the 871 productions submitted have taken time and trouble in their selection. More than 600 contributions have found wall space, and, as usual, several medals have been awarded. The most successful exhibitors include amongst the landscapists Mr. Karl Greger, with a series of pastoral and other rural subjects, platinum-toned prints, in which atmosphere and distance have come out very successfully; Mr. W. Bedford, who has several picturesque views in Norfolk, richly brown in tint; Colonel J. Gale, who combines rustic and marine scenery with figure groups very tastefully; Mr. B. Gay Wilkinson, with some dreamy twilight effects, two or three of which suggest brush-work and individuality rather than the exigencies of the camera; Mr. A. R. Dresser, whose contributions include a fine view of the meeting of Conway and Lledr rivers; and in marine photography Messrs. Elliot & Son, with a carbon enlargement seven feet by five feet in size, from a whole-plate negative by Birt Acres, representing sea waves breaking on rocks, and printed, to assist the illusion, in a decided green tone. Specially by itself must be noted a remarkable view of Mont Blanc, taken at a distance of fifty-six miles, with Dallmeyer's tele-photographic lens, by the late Mr. F. Boissonnas. In comparing this with a smaller view of the same by an ordinary lens one realises the remarkable character of this curious experiment, and to the practical photographer, be he amateur or professional, it should be of much interest. In portraiture Mr. F. Muller gains recognition for a man's head, in which the modelling and the expression of character in the face are forcibly represented; while, amongst numerous children's portraits, a medal is taken by Mr. W. M. Warneuke for a nearly life-size half-length of a little girl. Other medallists are Mr. Harold Roller, for direct portraits taken in a room, notably an excellent one of Miss Alma-Tadema; Mr. J. E. Austin for a couple of figure studies, excellent as to the pose and expression of the old man, who is mending a clock in one instance and perusing the contents of a bill in the other, both taken direct with spectacle lens; Mr. H. Yeo, for several photographs in different positions of a child blowing bubbles; Mr. Henry Stevens, whose flower pictures are unrivalled as reproductions of floral form and beauty of detail; and Mrs. Main, one of the best students of the pictorial attractions of frost and the shadows on snow. In a different branch of skill, that of photographic reproduction of pictures, the Autotype Company take a medal for their trancript of Mr. Edwin Douglas's Academy picture of horse and foals, entitled *Young England*. There are many contributions to the collection that are not far behind those mentioned in merit and value from various standpoints, and many well-known exhibitors who have taken so many of the Society's medals at different times that they should scarcely covet any more are prominently and well represented. From the Cameron studio we have Mr. Watts at work on his equestrian statue, and other contributions; Mr. Fred. Hollyer sends a dozen of his portraits of artistic, literary, and other "celebrities," for instance, Mr. Burne-Jones, Mr. Walter Crane, Mr. Andrew Lang, Mr. J. M. Barrie, Mrs. Ewing, and the Rev. Stopford Brooke; Mr. Birt Acres tells *The Story of a Cloud* in a set of photographs showing the change of form of a bank of cumulus clouds; Mr. Francis Blake, in his *Cow Pony* at sharp canter renders some mysteries of equine motion; Mr. J. B. Scott has some graceful full-length portraits of ladies; and Mr. W. J. Byrne some charming presentments of childhood. We may note also the luminous views in the Lake Country by Mr. E. Benson, Mr. H. W. Bennett's sea and boat photographs, a pair of frost studies by Mr. G. Renwick, sundry well-selected views of land and sea on a small scale by Mr. W. Thomas, and on one of the screens in the scientific branch may be studied the history of dentition, of various anatomical subjects, the cultivation of bacteria, and other matters helpful in the knowledge of ourselves and our enemies.

[*Morning Advertiser.*]

The annual Exhibition of Photographs by the members of the Photographic Society of Great Britain opens to-day, the introductory *soirée* having been held on Saturday evening. There have not been any great strides in the art since the Exhibition of last year, but there is a general improvement to be noticed in the majority of the pictures now hung in the gallery of the Royal Society of Painters in Water Colours. One of the great changes is the more extended use of very rough surface papers, which in pictures of a fairly large size is very effective; but unfortunately the desire to use the new paper has led to some of the exhibitors using it for pictures far too small from the artistic point of view for its use advantageously. There are also more prints on gelatino-chloride papers, and uranium has been more frequently used for toning, and carbon printing is more in evidence. If possible, the show is more popular than ever among photographers, though it is to be regretted that several of the best workers have not sent anything this year, probably in consequence of a little unpleasant incident which occurred at the last Exhibition. Notwithstanding that fact, however, there were more frames sent to go before the hanging committee than ever before. No less than 871 frames were sent, of which 633 are hung and 238 rejected. With regard to the rejected frames it is only fair to the hanging committee to say that, if the pictures were worse than some of those which were accepted, they must have been very bad indeed. These pictures are, of course, very few, and the general average of the work shown is high—so much so that from the point of view of artistic merit it is impossible to pick out one picture as the work of the year. This is explained by the fact that, as the merit of a photograph almost entirely depends on the subject chosen, and not on the subsequent manipulations, the higher the average of artistic merit the less the chance of any photographer producing a picture strikingly more artistic than that of the other exhibitors. Dealing now with the pictures, the one which will first strike the eye of the visitor will be a large sea piece (No. 250), probably the largest that has yet been hung at a photographic exhibition. It measures seven feet by five, and is a carbon enlargement, in a green tone, by Messrs. Elliott and Son, from a photograph by Birt Acres. It is a wonderful piece of work, and the sea is beautifully transparent, but one feels that it is too large, it is difficult to comprehend it from one point of view. As an enlargement it takes a medal. Karl Greger secures a medal for six pretty little pictures (No. 5) of rural scenes, mostly containing sheep, the choicest being *Homeward*. B. Gay Wilkinson gets a medal for a series of six pictures (Nos. 50–3), all of which are charming, but the best is that of the *Palaces of Parliament*, with the sun setting behind the Victoria Tower. W. Bedford takes a medal for a carbon print, *Salhouse Dyke, Norfolk* (No. 67), in a warm brown tone, of a winding stream with trees on the further bank, and beside which the fisherman has left his rod hanging over the water. Colonel J. Gale is awarded a medal for *The Incoming Tide* (No. 79), another effective carbon print. A. R. Dresser takes a medal for a picture of *Aylesford* (No. 140), a uranium-toned print on rough paper, the effect being a warm brown, and the view is looking across the stream to the town. It is an effective enlargement from a hand-camera negative. H. Yeo deservedly gets a medal for a series of fine pictures (141-144) of a little girl blowing bubbles, and for three portrait studies in a red tone, very soft and pleasing. F. Muller secures a medal for a fine portrait (No. 146) in a brown tone on rough paper. J. E. Austin gains a medal by *Worn Out* (No. 184), a picture of an old man examining a clock of somewhat ancient manufacture; the picture is excellent, and is taken with an ordinary spectacle lens. Henry Stevens' flower study of *Meadow Sweet* (No. 201) is very fine, and fully deserves the medal awarded to it. Mrs. Main is awarded a medal for six pictures, entitled *Frost and Snow* (No. 212), which are certainly the finest snow pictures that have been

exhibited. Snow is very difficult to photograph successfully, a fact which can be verified by comparing these pictures with some others hung close by, which are also the work of clever photographers. J. Harold Roller sends four pictures (No. 229) taken in an ordinary room, for one of which a medal is awarded. The portraits are admirable, and afford a good example of what a determined worker can do without a studio. W. M. Warneuke takes a medal for a beautiful portrait of a little girl (No. 243) in a white sun-bonnet, which is one of the prettiest and most successful studies on the walls. F. Boissonnas takes a medal for a very clever piece of work. It consists of a view of Mont Blanc (No. 404), taken at a distance of fifty-six miles, with an ordinary lens, about 5 inches square, and a portion of the same view taken from the same spot with Dallmeyer's new tele-photographic lens—a picture about 24 inches square, in which every detail is perfectly distinct and clear. The Autotype Company take a medal for an autogravure (No. 418) of Edwin Douglas's picture *Young England*—two mares and foals in a field. In lantern slides E. G. Lee takes the medal for a series of twelve (No. 637) from negatives taken with a home-made camera. The slides are pictures, and speak well for the effectiveness of the home-made camera. Among the pictures not medalled there are two at least which will strike the observer as deserving of such recognition—one, *The Love Letter* (No. 206), by A. Burchett, a charming study of a girl standing in a day dream beside a spinning-wheel, with an open letter in her hand, and the other a portrait study in red chalk (No. 196), an autotype reproduction by the Autotype Company of a large head taken by Downey & Co. F. Boissonnas sends a fine picture, *A Sunset Study* (No. 30), being a view of a hayfield, with three women in the foreground. Another peculiar print is H. J. Godbold's *Rocket to the Rescue* (No. 96), a photograph of a stranded ship with a rocket just fired to carry a life-line to it. The rocket is shown very distinctly. E. S. Dashwood's *Where there's a will there's a way* (No. 132), four pictures giving the history of a cat getting cream out of a jug on its paw and then licking it, will be a favourite, as will also be Henry Stevens's cat and dog studies, *A Trained Nurse* (No. 150) and *Tired Out* (No. 173). Birt Acres' five blue pictures (No. 162), showing the formation of a cumulus cloud, will attract attention, as will also Francis Blake's four instantaneous photos of *Cow and Pony* (No. 168) at a sharp canter. Many visitors will think W. J. Byrne's fine *Grecian Girl* (No. 174) to be very much like Mary Anderson. E. Lambert shows a fine series of girls' heads (No. 217), taken with a single landscape lens, which are clear proof that as good portraits, if not better, can be taken with such a lens as with any compound ones. Window and Grove send three studies (No. 218) of Miss Ellen Terry as *Queen Katharine*, which are good, as is also Gabell & Co.'s *Head of a Boy* (No. 224). *Professor Herkomer* (No. 238), by the same firm, is excellent. *Scenes in North Africa* (No. 304), and a series of tropical pictures (Nos. 295–302), by E. F. im Thurm, C. M. G., are very interesting. *Worn Out* (No. 370), by F. Whaley, is rather a pathetic picture. It shows an invalid boy asleep in bed, with the father, who has been sitting up with him and reading the paper, having also fallen asleep, the paper having dropped from his hand. There is a lighted candle on the table, and the dawn can be perceived through the window.

The show of apparatus is very meagre, the most striking piece being a camera, by Watson & Son, to take pictures 2 feet square, attached to a very ingenious stand, all the movements in which are regulated by one handle close to the operator. An aluminium tripod by Newton & Co. is very light, but rather conspicuous for use. The "Frena" hand camera by R. & J. Beck is extremely ingenious and compact, and will carry forty cut films. It is also very compact. Messrs. Crouch show the "Dresser" hand camera, another very useful form of instrument. The only medal in this section is taken by Messrs. Taylor, Taylor, & Hobson for a new system of fitting lenses, by which the flange of one lens fits into that of the size larger, so that a large number of lenses can be conveniently used in the same camera, and the screws are so constructed that there is no difficulty whatever in fitting the thread and screwing them into each other.

[*Standard.*]

Those who practise photography are usually artists. It is natural, therefore, that the interest in the annual Exhibition of the Photographic Society of Great Britain should be artistic rather than scientific. From this pictorial point of view, the work is of a higher standard than that of any previous year. The number of pictures submitted to the hanging committee has been greater, and more care has been taken in selection. Nor has the scientific interest been altogether neglected. The advances made in this direction during the last twelve months have not been remarkable, except in a single instance, of which an example is given in No. 404. This is a photograph of Mont Blanc, taken at a distance of fifty-six miles. Dallmeyer's tele-photographic lens was used, smallest stop, extension of camera 60 inches, with seven minutes' exposure at 6.15 p.m., August 27, in windy weather. The success of Mr. F. Boissonnas' experiment with the telescopic camera is unquestionable, and opens up many interesting possibilities. A perfect view of Mont Blanc even at this great distance has been secured, and opportunity of instructive comparison is offered with smaller photographs taken with an ordinary lens at similar and closer ranges. Another exhibit (No. 96) has some scientific, though little or no artistic, attraction. Even the uninitiated have ceased to be astonished at the lightning records of the camera. Daguerre found seven or eight hours' exposure necessary to procure a copy of a landscape that may be obtained now in an infinitesimal fraction of a second. Notwithstanding this familiarity with speed, it is worth noting the success with which Mr. H. J. Godbold has caught a rocket in its flight from the shore to a ship in distress. The colour is bad, but this is an unavoidable effect of short exposure and of the conditions under which it was presumably made. One or two mechanical improvements may be observed in passing. A new system of lens flanges and adapters has been introduced during the year. The screws are made to engage at one turn, and without the possibility of crossing threads, while the diaphragm indexes fall into a uniform and convenient position. It is hoped that the popularity of this system will facilitate the efforts of the Society to introduce a standard uniformity of lens flanges and adapters, an arrangement that will commend itself to amateur photographers.

Turning again to the pictures, it will be seen that by far the greater number are platinum and albumen silver prints. There is abundant evidence also of the prevailing disposition to cultivate low tones, and to take advantage of the effect of rough paper. How charmingly delicate and varied these effects may be is seen especially in the landscapes. This is a department in which the Exhibition is strong. Many of the prints will compare favourably with the finest engravings or etchings for refinement of line and softness of tone. For example, it would be difficult to discover anything more perfect than Mr. Gay Wilkinson's *The Peaceful Evening Hour* (No. 51). It is a small landscape, into which a pleasant atmospheric effect has been imported with remarkable skill. Colonel Gale, a well-known amateur, has also been very successful with a series of views (Nos. 79–75), of which the lines are sharply defined without being hard. Equal commendation is given to Mr. Bedford for his scenes on the Norfolk Broads. In common with many other exhibitors, Mr. Bedford has adopted carbon printing, the artistic possibilities of which on a large scale may be seen in a 7 ft. × 5 ft. enlargement of a sea view by Messrs. Elliott & Son (No. 250). The print is from a whole-plate negative, and, although in four pieces, is put together so skilfully that only the closest inspection can detect the joints. It is a remarkable work, even less on account of its size than of its artistic merits as a representation of the broken waters and lights of the sea. Amateurs, and even professional photographers, who have taken snow views, will appreciate the success with which Mrs. Main has overcome the difficulties in her series of prints (No. 212). In portraiture there are many interesting studies. Several of the most artistic are, however, hybrid, having been touched with the brush or crayon. Of the purely photographic examples, the most successful is Mr. F. Muller's (No. 146), the head of an old man. The line and colour are excellent, and remind one of the work of Velasquez. Mr. J. E. Austin's two pictures, *Worn Out* (No. 184) and *To Account Rendered* (No. 185), are a little "plumy" in colour, though they are very pleasant studies, and notable as having been taken direct with a spectacle lens. Upon the walls may be seen not a few examples of the use to which the camera may be put in multiplying pictures. The reproduction (No. 418) of a picture exhibited at the Royal Academy, by Mr. Edwin Douglas, has secured for the Autotype Company a medal. It is a close imitation of an etching, in which not only the brush work, but the atmospheric effects of the original are reproduced with astonishing fidelity. The screens and portfolios contain many prints that deserve attention. There are instantaneous photographs that may interest tennis-players and physiologists, photo-micrographs that will charm anatomists and students of bacteria, lantern slides of educational and artistic value, and celluloid film negatives that prove what great advances have been made with this substitute for glass. Altogether the Exhibition is of high technical and artistic interest, and its popularity may in some measure be predicted from the crowds of visitors who accepted Captain Abney's invitation to the *soirée* on Saturday evening.

[*Pall Mall Gazette.*]

The annual exhibition of the Photographic Society of Great Britain, opens to-day in Pall Mall. There was a *soirée* on Saturday, when visitors who were mere laymen were astounded by the inspection of a photograph of Mont Blanc taken at a distance of fifty-six miles. Dallmeyer's tele-photographic lens was used, smallest stop, extension of camera sixty inches, with seven minutes exposure, at 6.15 p.m., August 27, in windy weather. The success of Mr. F. Boissonnas's experiment with the telescopic camera is unquestionable, and opens up many interesting possibilities. A perfect view of Mont Blanc even at this great distance has been secured, and opportunity of instructive comparison is offered with smaller photographs taken with an ordinary lens at similar and closer ranges. Another exhibit has some scientific, though little or no artistic attraction. Even the uninitiated have ceased to be astonished at the lightning records of the camera. Daguerre found seven or eight hours' exposure necessary to procure a copy of a landscape that may be obtained now in an infinitesimal fraction of a second. Notwithstanding this familiarity with speed, it is worth noting that Mr. H. J. Godbold has very successfully caught a rocket in its flight from the shore to a ship in distress. The colour is not all that it should be, but this is an unavoidable effect of short exposure, and of the conditions under which the picture was doubtless made. As a whole, the excellence of the Exhibition is very striking, and Captain Abney may be congratulated upon the result of his efforts in getting it together.

[*Daily Telegraph.*]

TELE-PHOTOGRAPHY will apparently create a new field of activity for the lovers of the camera. At the annual Exhibition of the Photographic Society of Great Britain, which is open in the Gallery of the Royal Society of Painters in Water Colours, Pall Mall East, Mr. F. Boissonnas has a truthful picture of Mont Blanc, the negative of which was obtained by T. R. Dallmeyer's new lens, with an exposure of seven minutes, on August 27 last, in windy weather, at a distance of ninety kilometers (fifty-six miles). The photograph was taken direct, and is untouched. Messrs. Elliott & Son have been awarded a medal for their realistic enlargement, seven feet by five feet, of a sea piece—a breadth of broken waters. The print is in four parts, neatly jointed together. Artistic photography is making rapid strides, the use of rough paper being as helpful to the printing as it is in water colour. Sepia tints and broad wash effects are popular; but there are examples also of the school which delights in detail and definition. Amongst the most taking subjects are those shown by Mr. Gay Wilkinson and Colonel Gale. In portrait studies, Mr. F. Müller and Mr. J. E. Austin excel.

[*Times.*]

THE leading points of interest in the Exhibition lose, no doubt, considerably from the abstentions to which we have already alluded—abstentions which, among other things, leave almost unrepresented a class of work which has of late years come to the front—we mean that in which the higher forms of art are applied to photography. Under such circumstances it is difficult to award unqualified praise. Still, there can be no grounds of complaint that one of the Society's medals has been awarded to Mr. Karl Greger for his very charming little set of pictures (No. 5). Mr. H. H. Cameron's studio, which continues the traditions of his late mother, Mrs. Julia Cameron—a name which will long continue to hold a foremost place in figure work—contributes an excellent portrait of Mr. G. F. Watts (No. 4). The best work in the Exhibition is, undoubtedly, that of J. S. Bergheim, of Vienna. His two heads (Nos. 18 and 23) are of excellence which deserves more recognition than they have obtained at the hands of the judges. Most noteworthy, too, is Burchett's *The Love Letter*. Close by hangs a small piece (No. 9) by J. P. Ennis. There is poetry in the solitary bent figure wending his way in the evening sunlight across the common—poetry which we miss so frequently in photographic work. Colonel Gale's little *saynètes* are characteristic of a well-known photographer, perfect in execution, faultless of their kind. Mr. Gay Wilkinson's set illustrates the power which photography gives us of reproducing the beautiful effects of cloudland. The pictures are very good. F. P. Cembrano contributes a few pieces, *hors concours*. He inclines to the misty effects of Thames scenery, and his work is always remarkable. Mr. Dresser has been for years a prominent exhibitor, but he fails this year in attaining his usual standard. If not exactly pictures, Mr. H. Stevens's groups of dogs and cats (No. 173) are remarkable instances of the power which photography gives us of producing minute detail. It is impossible to pass by the head of an old man by F. Muller, of Munich (No. 146). What a model! And it is well treated; it will grow upon those who examine it. J. E. Austin's figure pieces (Nos. 184 and 185) are taken with a spectacle lens. To the uninitiated it may be necessary to explain that this means such a glass as we are accustomed to use for an eye-glass. The results, technically, are surprising. The subjects, however, are trivial, though no doubt of a character which will be popular. Remark the portrait of Professor Herkomer, by Gabell & Co. It has many points of excellence. The professional studio work is of the usual character. The stereotyped mechanical retouching, done, as a rule, without any knowledge of the sitter, cannot be too often denounced. Yet the public accept it—indeed, insist upon it.

Our survey of the pictures is necessarily brief. The Exhibition is not up to the standard which it might, under other circumstances, have attained. At the same time there is less absolutely bad work than usual. The committee have shown a laudable desire to profit by many reasonable complaints which have lately been made, and, contrary to the usual practice of the Society, they have rejected a large number of contributions sent in. But there remains much more to be done, and it is in the interests of the Society itself that we have mentioned questions which it will have to face.

Our Editorial Table.

A VOLUME BY THE HOLBEIN SOCIETY.

Manchester: A. BROTHERS, 14, St. Ann's-square.

THIS interesting work is a reproduction in *facsimile* of the edition of Dr. Martin Luther's *Catechism for the People, Pastor, and Preacher*, which was printed in Frankfort-on-Main in 1553. We have more than once had occasion to speak of the masterly way in which Mr. Brothers, by his process of photo-lithography, has reproduced in *facsimile* the *Dance of Death* and other works issued by the Holbein Society. It is enough here to say that, as regards distinctness and perfection of typographic outline, it is scarcely possible to conceive of the Frankfort edition being in any particular better than this, or even so good, when we take into consideration the fading of the ink which must necessarily have taken place in the original during the 340 years that have elapsed since it was printed. The work contains numerous drawings in addition to the text, which, it is scarcely necessary to say, is in German. The Society is to be congratulated upon the enterprise displayed in reproducing such scarce works.

"DRY PLATES."

Edited by CADETT & NEILL, Ashtead.

To those who employ the excellent plates of this firm, the information given in this, the first number of a monthly pamphlet they are issuing, should prove serviceable. Mr. Cadett himself contributes a most instructive article on "Ammonia in Development," in which he discusses the best way of keeping and using that alkali.

THE HAND CAMERA, AND HOW TO USE IT.

By WALTER D. WELFORD. London: Iliffe & Son, 3, St. Bride-street.

FIRST of all, discussing the hand camera in its different forms, together with the uses of its parts in their numerous variations, Mr. Welford proceeds, in the same exhaustive fashion, to deal with its manipulations, in the course of which he supplies a complete *vade-mecum* to its employment. Mr. Welford has devoted a great deal of time to practical hand camera work, of which he is a successful exponent, and this volume is, doubtless, the result of his own experiences. We can confidently recommend a perusal of it to all those who are contemplating hand camera work, who are thinking of taking it up, or who, having failed, are desirous of knowing the causes of their failures with a view to remedying them. Price 1*s*.

THE PHOTOGRAPHIC LENS.

By T. R. DALLMEYER, F.R.A.S., M.R.I., &c.

AN elegant illustrated pamphlet of thirty pages, giving such a full description of the tele-photographic lens of Mr. Dallmeyer as suffices to answer every question that can be put relative to either the construction, use, or mode of working the lens. It contains a synopsis of what has appeared in the various journals in regard to it, and is embellished with six plates and several cuts.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
October 3	Dundee Amateur	Asso. Studio, Nethergate, Dundee.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

SEPTEMBER 27,—Technical Meeting,—Mr. W. England in the chair.

The meeting was held in the gallery of the Exhibition, and the apparatus on view was explained.

Among the few novelties shown and explained was Mr. W. Sanders' opera, field, or marine glass, which can be converted into a photographic camera and lens without altering its outward appearance. It then contains a telescope, twin photographic lenses, time and instantaneous shutter, metal roll holder

with twenty-four exposures), ground glass screen, and magnifier for focussing, all enclosed, the only projection being the shutter trigger, which does not protrude a quarter of an inch The instrument is focussed in the manner of all binocular glasses, and, when the picture is seen to the best advantage, it is secured while still visible through the glass. The time of exposure is regulated at will while viewing the picture, the shutter being always ready for either the shortest or longest exposure required. It is extremely portable, and may be directed towards a scene or object without arousing the slightest suspicion as to the object the possessor has in view. The largest-size picture capable of being taken by the instrument is 2×2; but, owing to the system of focussing, which may be changed from telescopic to photographic without removing the glasses from the eyes, they can be produced with microscopic sharpness, which will bear enlarging.

Messrs. Smith then explained their patent plate washer, the advantages of which are thorough circulation of the water in the tank, films face downwards, and the complete emptying of the tank once in every five minutes, causing complete elimination of the soluble salts in very little time. The sloping bottom and the washing-down action of the water inlet prevents the usual incrustation of hypo on the bottom, all deposit being ejected each time the large syphon acts, so that the plates are washed in successive quantities of pure water instead of in the usual more or less diluted hypo, and great saving effected in the quantity of water required.

Among Messrs. G. Houghton & Son's exhibits, Mr. W. G. Tottem showed the following novelties:—A revolving disc for vignetting, which, when wound up, carries a number of frames, thus preventing any hard lines. It would carry frames to a weight of 100 lbs. Mr. Tottem also showed an ordinary pen-knife with a diamond for cutting glass, and an interchangeable album in which the sheets are detachable by drawing out a small catch.

Mr. J. A. Sinclair showed Messrs. Adams & Co.'s lightning camera stand, weighing about 2 lbs., which is very rapidly opened and folded up, the legs bending instead of sliding; also the same firm's Vesta pocket camera and the new Adams' changing-back for ordinary cameras, carrying twelve plates in a small space, and being of the same register as an ordinary dark slide.

In explaining Messrs. Watson's exhibit, the firm's representative drew attention to many improvements in the Acme camera, one being the hinging under each other of joints of the shutters of the dark slides; and the decrease of weight on account of the use of aluminum, which, he stated, had been found easy to work (a 10×8 weighing 4¾ lbs.).

The other exhibits were explained by Mr. Howard, who said that the principal feature of the Dresser hand camera (H. Crouch) was that it had a rising front, and could be used as an ordinary camera with a screen in the usual way.

Mr. Gotz's, Messrs. Morley & Cooper's, Messrs. Newton's, Beck's (including a wooden model of the system of releasing the films and cards employed in the Frena camera), Archer & Son's lantern (with improved ventilating arrangement by which moisture in the condenser is obviated), and other exhibits, were also referred to.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

September 22,—Mr. J. Traill Taylor in the chair. There was a large attendance, and several ladies were present.

Mr. E. H. Fitch was elected a member of the Association.

The following question from the box was read: "In gelatino-bromide emulsion, what are the advantages, or disadvantages, of using a large or small proportion of gelatine in relation to the amount of bromide of silver?"

Mr. W. E. Debenham said a large proportion made it easier to obtain a fine emulsion; but it made the development and fixation much slower and the film more apt to stain.

Mr. W. P. Dando showed the programme provided by Sir Augustus Harris when the German Emperor visited the Italian Opera last year, on which occasion (said Mr. Dando) certain of the French artists at the last moment refused to sing, so that the programme had to be suddenly altered, and a portion of it taken out and replaced by other matter. Mr. Dando wished to know what the approximate cost of the alteration should be. He believed the programme (apparently a collotype picture on silk) was done abroad at an original cost of 300*l.*, which, with the alterations, had been brought up to 500*l.*, an amount Sir Augustus Harris refused to pay.

Mr. T. Bolas said such work would be produced from two negatives in the ordinary course of things.

No other answer was given to Mr. Dando's question.

Samples of amidol were distributed among the members.

The Limits of Photography.

Miss Catharine Weed Barnes read a paper on the *Limits of Photography* (see page 632), at the conclusion of which,

Mr. P. Everitt said that twelve or eighteen months before he was presumptuous enough to draw the attention of members of the Society to Dr. Emerson's work, and since those discussions they had had time to think over how the problem stood, he himself had been struck by the similarity between the development of painting and photography as compared with each other. In painting there had been a gradual departure from minute detail. The presentation of what was seen or what was imagined in all its detail was the rule in the past; but a characteristic feature of modern work was an element of mystery and a lack of definition which considerably excited the imagination. There was a similar progress in photography. He thought that in the past they had given too much attention to detail, and they looked now to broad effect and some want of definition so as to aid a story and excite the imagination. Having referred to the advantages which the painter had in being able to suppress or render detail at will in such a way as best to tell the story he wished to, Mr. Everitt pointed out that the photographer had little or no control in these respects over particular parts of his pictures, the power only being little and not comprehensive as in the case of the painter. Therein, he thought, lay one of the limits of photography. As regards reproductions of pictures in monochrome, as well as the copying of any subject or object for scientific purposes, he thought photography excelled any other of the graphic arts. For example, in the power of rendering lace no artist could equal a photographer. He hoped that in twenty or thirty years' time photography would stand on a much higher footing than at present.

The Chairman said, with regard to improvements in lenses (as suggested by Mr. Everitt) designed to enable one to select portions of a subject, that he feared that it was almost impossible. The photographer must have his subject before him, while an artist was able to carry it away in scraps.

Mr. Everitt said his reference was as to what portions of a subject should be sharp; and there a difficulty presented itself, that of how to accentuate a subject on widely different planes.

Miss Barnes referred to one of her negatives wherein the sky was defective, and in making a bromide print of which she developed up from the bottom of the picture, and so made the hills look about twenty miles away, whereas in a silver print they had only looked about five.

Mr. Debenham said it was a fallacy to suppose atmosphere was to be got sometimes by the bad definition of a lens, as though ordinary photography did not render it. Photography did thoroughly represent it, as in the case of McLeish's picture of *A Misty Morning on the Wear*. As regards the differentiation of planes, photography was capable of rendering it, and did render it, sufficiently, but if a photograph was much under-exposed, or made too intense, or printed too dark, they might lose the effect. Atmosphere is and could be rendered by photography independent of any blurring or out-of-focus effects with defective lenses.

The Chairman said that one of the finest examples of true atmospheric effect he had seen was an enlargement of a small picture of Durham Cathedral by Mr. R. L. Kidd (Messrs. Morgan & Kidd). The trees in the immediate foreground were sharp and bright, and the cathedral itself, across the river, was also sharp, but misty. Such an effect could never be obtained by simply putting the distance out of focus.

Mr. Debenham (continuing) said that artists said fine definition destroyed atmospheric effect.

Mr. Everitt said what was said was that one could not get atmospheric effect with sharp definition, but that with sharp definition one got sharp atmosphere. A certain amount of haze was always present in the air, by which the idea of distance was obtained.

Mr. Debenham said if atmosphere was present it would prevent definition, and they had to be content with the best focus the lens would give. In reference to another part of Miss Barnes's paper, Mr. Debenham deprecated jealousy between amateurs and professionals, and thought that the bringing of pressure on to dealers, &c., in order to get favourable terms was unworthy of professional photography.

Mr. H. E. Davis did not see where was the difficulty mentioned by Mr. Everitt as regards obtaining aerial perspective, and thought that with a sharp negative subsequent manipulations in printing would produce the desired effects. Of course, it required great care, but the effects of aerial perspective had been produced that way, and would, he thought, be continued to be produced in a similar manner.

Mr. Bolas said that with reference to Mr. Everitt's idea of being able to control local definition with a lens, the only contrivance that would produce the effect would be an ideally perfect lens in front of the camera. He could not assume the possibility of such a contrivance, but he thought that some kind of screen in front of the plate might be used for the purpose.

Mr. J. S. Teape said, in connexion with the art education of a photographer, he could say from experience there was nothing of greater value to him—even if he had only studied in the most elementary stages he would find it a most valuable power, particularly in respect to composition. It could always be seen whether a photographer had studied art or not, as he was certain to show it in the selection of his pictures.

The Chairman mentioned the unsuitability of the horizon line in many photographs, mistakes which a little artistic knowledge of the most elementary kind would save.

Mr. A. Clarke said he must plead guilty to having ordered backgrounds with the horizon line much below where it should be. He thought it gave dignity and majesty to a figure. The method was adopted by Reynolds and other artists. In regard to a suggestion of the Chairman as to sunning down white parts of a picture by judicious exposure to light, he thought such a method gave flatness. He would prefer to rub down a negative with spirit.

Mr. W. H. Harrison said that, at a recent meeting of the British Association, Colonel Tanner had stated that he had tried to find out if photography could replace the theodolite in surveying work, and there were differences of opinion on the subject. Some said they could measure distance to within five or six seconds of arc. The French had come to the conclusion that a pinhole lens was the best for the purpose, but the distances did not come out in the right proportion. It was a pity Colonel Tanner's paper was brought before the wrong section of the Association.

After further discussion, a cordial vote of thanks was passed to Miss Barnes for her paper.

A Novel Method of Packing Plates.

Mr. A. Cowan showed practically a new method of packing plates, which had been in use for twelve months, which did away with the use of paper, nothing being placed between the plates themselves. It consisted of cutting through the glass of the plates, and leaving the film uncut, the plates being thus packed face to face in pairs of equal size, and easily detached when required for use. There was sufficient hinge in the gelatine to stop any pressure or abrasion. It had been found an advantage to have the plates thus packed.

In reply to a question, Mr. Cowan showed that there was no fear of tear in the films.

The meeting then terminated.

North London Photographic Society.—September 20, Mr. A. Mackie in the chair.—After the usual preliminary business, the Secretary reported that, having tried the new developer "amidol," he had found it to work very satisfactorily. In some cases, according to exposure, he had found it difficult to obtain printing density, but, from the character of the image and the clearness of the shadows, after intensification gave no trouble, and worked well. As a

one-solution developer it appeared to fill the claims made for it. The Secretary further reported that he had received tickets for the annual exhibition of the Photographic Society of Great Britain, which, under the affiliation rules, were to be obtained by members at half price. Mr. Redmond Barrett then gave a practical demonstration of *Retouching*, showing, with regard to negatives brought by himself and by members, what should not be attempted, what ought to be done, and how to do it. Scratches, pinholes, and other defects were also dealt with, and the best mode of dealing with such explained and illustrated. With regard to the use of retouching medium, Mr. Barrett advised the use, not of the finger tip, but of a tuft of cotton wool, with which a very small quantity of medium should be well worked, not merely on but into the film. Should any of the work come away in the subsequent varnishing it would have to be made good when the varnish was dry; in fact, it was generally desirable to make any finishing touches at this stage. The subject was found exceedingly interesting, and a cordial vote of thanks to Mr. Barrett concluded the proceedings. Next meeting October 4, Optical Lantern Night.

North Middlesex Photographic Society.—Mr. J. C. S. Mummery in the chair.—One new member was elected, and about forty members were present. The Chairman introduced Mr. E. J. Wall, who discoursed on the *Life of a Dry Plate*. He started with the making of gelatine and the properties of bromine, the making of an emulsion, the necessity of bromide being in excess, the advantage of an iodide, and the method of increasing rapidity by adding ammonia and by cooking. The qualities of a good plate were discussed, and the advantages of colour-sensitive plates. He then gave a recapitulation of the theories which had been advanced to account for the action of light upon a plate, and followed on with a consideration of the qualities of the numerous developers in use. He strongly advised beginners to leave hydroquinone alone, and to trust to pyro and ammonia. In looking over prints sent in to the *Amateur Photographer* competition, he had selected 300 prints as showing the faults usually given by the use of hydroquinone, and, on reference to the details given by the competitors, had found that in over 1000 instances his judgment was correct. When hydroquinone was used, he advocated the abolition of sulphite of soda, and advised the use of ammonia or carbonate of potash, with ordinary table salt as the restrainer when one was necessary in place of bromide of potassium. He considered that sulphite of soda was used in excessive quantities even with pyro. If negatives free from stain were required, they could be had by the use of the acid fixing bath. He referred to the theories of development advanced by Messrs. Hurter & Driffield, and mentioned the misunderstanding that had arisen in consequence of these gentlemen using the word density in a sense different from that in which photographers applied it. Having given a caution on the subject of thorough fixing, Mr. Wall boldly attacked the question of which intensifier to use according to the nature of the negative and the subject. In the conversation which followed many other questions were raised which Mr. Wall fully answered, and, on the motion of Mr. Marchant, seconded by Mr. Beadle, received a hearty vote of thanks. The competitions of views taken at the last two outings of the season to Higham Park, and the Rat's Haunt, Palmers Green, were held. Mr. A. J. Hewson was declared the winner in the former. The "Bynoe" printing frame was shown and price-lists of the Hill Norris Dry Collodion Plate, lists of new lenses, lists of chemicals from local dealers, &c., for which the Secretary tenders his thanks, were distributed. The next meeting will be held on October 10, when Colonel J. Gale will address the Society on technical points on picture-making, illustrated by the optical lantern. Visitors welcome.

Holborn Camera Club.—September 17, Mr. J. Stevens in the chair.—Mr. F. C. D. Beacham demonstrated the use of his patented pigments for spotting and retouching, and his liquid water colours for tinting photographs. With regard to the former, the pigments are put up in various forms—in crayons, cakes, or liquid. Any of them answer well for retouching purposes, and can be used upon the bare negative without either varnish or medium. For spotting prints the cake or liquid is used, and can be applied either before or after enamelling or burnishing. It can also be used dry for spotting platinotypes or bromides, and any other papers with a matt surface. Mr. Beacham also tinted some silver prints with his liquid water colours and a very satisfactory result was obtained. It seemed to be a very simple process indeed, and, if we cannot get photography in natural colours, we can tint our photographs afterwards and get something very nearly approaching it. On Friday, September 24, quite a large number of members' slides were thrown on the screen. The first were by Mr. F. J. Cobb, and among them were some of the Southern Counties Cyclists' Camp at Dorking this year, followed by some of Amersham and Chenies. Some by Mr. T. O. Dear followed, mostly studies of the Cyclists' Camp, and then a large number by Mr. J. H. Avery. Some of these were excellent slides, and included some of the upper Thames scenery, inland scenery, with a few animal studies. A small set by Mr. A. T. Ebsworth, all of the Cyclists' Camp, concluded a very pleasant evening.

Hackney Photographic Society.—September 20, Mr. F. Houghton in the chair.—Mr. B. Wire was nominated. The particulars of the last excursion of the season (to Hampstead) were given. A tea and smoking concert at the "Bull and Bush" was decided on. Mr. A. Barker showed prints he had executed with amidol on bromide paper. Mr. Carpenter showed some lantern plates he had made with it, also a print which, very thin, had obtained good platinum print with it. Other work was shown by Messrs. Pollard, Gosling, Dean, &c. The Developan Company then showed their speciality. Mr. DANDO was afraid the top glass (light) was not safe, but was informed that, as it was not directly exposed to the light, there was little danger of fog. In answer to a question from the Hon. Secretary respecting the suction of plate, it was said to be an advantage. Mr. Nunn then had the Developan handed to him for trial and report at next meeting. Mr. Carpenter showed a brown-paper "dark back." Some discussion ensued respecting the limit of attendances for competing in the exhibition, in which Messrs. Gosling, Beckett, Dean, Wesson, Barton, Dando, and others took part. Meetings are held every Tuesday at 206, Mare-street, not Morley Hall as heretofore, and the Hon. Secretary's address is now 12, King Edward-road, N.E.

South London Photographic Society.—September 19, the President (Mr. F. W. Edwards) in the chair.—A large number of prints from negatives made on samplee of Paget plates were handed in for competition for the President's award for the best picture. The President, who was assisted in the judging by Mr. Walter Woodbury, of the Paget Prize Plate Company, awarded the prize, a fine 12×10 platinum print of Shanklin Chine, to Mr. C. H. Oakden, and stated that Messrs. Buckle and Kelly followed close behind him in merit. Owing to illness at home, Mr. W. Groves was unable to read his paper on *Photography in Natural Colours*, and his place was filled by Mr. Mark Boxall, who, in the course of his remarks, dealt with all the *Recent Discoveries*, which by some were calculated to attain the desired end. In the end, the lecturer, in his usual characteristic style, declared that all the inventors were on the wrong tack, and stated that, if photography in natural colours was attained at all, in his opinion it would be through the agency of some of the tar compounds. Mr. Boxall's remarks were strongly criticised by several of the members present. By the courtesy of the importers, samples of "amidol" were distributed among the members, who were to report their experiences of its properties to the next meeting. Attendance, thirty-three.

Brixton and Clapham Camera Club.—September 20, Dr. Reynolds (President) in the chair.—The subject for the evening was *Exposure and Development*, the discussion on which was to have been opened by Mr. W. Bevins. In the unavoidable absence of this gentleman, Mr. J. A. Butler undertook to do so, and read a short paper, addressed principally to beginners, for whose benefit the meeting was chiefly intended. Referring to exposure, Mr. Butler said that this necessarily depended largely upon the aperture of the diaphragm used with the lens, and explained that, in order to form any correct idea upon the subject, it was necessary to ascertain the ratio of the aperture to the solar focus of the lens. In order to avoid complications, he advised the use of two stops only, *f*-16 and *f*-32, the former to be used when a short exposure was necessary, and the latter when time was no object. If this plan was adopted, and one kind of plate only used, he said a sufficiently correct judgment of exposure was rapidly and easily acquired. Besides the aperture of the diaphragm used, exposure was influenced by the distance, colour, and degree of illumination of the subject it was desired to photograph and the sensitiveness of the plate. The degree of illumination could be estimated by observing the height of the sun above the horizon and the state of the atmosphere. He advised that a full exposure should be given whenever possible, as it was only when this was the case that any control whatever could be maintained over the character of the negative during development, and said that the amount of latitude in exposure possible with plates of good quality was very great indeed, assuming careful development. For the developer Mr. Butler recommended the use of pyrogallol, potassium bromide, and ammonia in ten per cent. solutions, and said that the pyro could be preserved in solution for an indefinite period by the use of either potassium metabisulphite (half ounce to one ounce pyro) or sodium sulphite (four ounces to one ounce pyro), acidified with strong sulphurous acid. The character of the negative varied as development was allowed to proceed quickly or slowly. Rapid development gave a soft or even flat negative, slow development a vigorous or even hard one. Mr. Butler recommended the acid fixing bath, which could be made by adding a small quantity of bisulphite of sodium or metabisulphite of potassium to the ordiuary solution of hypo. Some discussion followed, in which many points of interest in development were touched upon, and, on the motion of the Chairman, the usual vote of thanks was passed to Mr. Butler. It was announced that the winter session would commence on Tuesday, October 4, and that meetings would be held on the first and third Tuesdays in each month. The dates for the annual exhibition of the Club were fixed for November 17, 18, and 19.

Croydon Camera Club.—One of the most successful of this season's field excursions was held on September 17, not because of the weather—which was, however, gloriously perfect for such an outing—but because of the conductor, Mr. B. Gay-Wilkinson. The morning was remuneratively spent near Limpsfield, where Mr. Wilkinson, with his characteristic energy, improvised a number of subjects for his followers to portray. These included such scenes as "Thumbit Lunch," and "Plough-land Work." In the afternoon Pains Hill was visited, and scenes illustrating "Gathering" and "Cottage Life" attempted. Mr. Wilkinson proved, as was to be expected, very unlike the ordinary conductor, who merely trots round with a party of perspiring picture-seekers, and whose ambition seems to be to break a record in distance covered, for he fulfilled the legitimate functions of a leader by not merely visiting interesting places, but by explaining, and to a large extent showing, by ocular demonstration, how the prosaic beauties of nature may be turned into poetical ones, or, at any rate, receive a palpable impress of artistic sentiment. The usual fortnightly Monday evening meetings begin on October 3. We understand an unusually interesting series of demonstrations and papers will be given during the winter, further particulars of which will be shortly announced.

Birmingham Photographic Society.—September 22, Mr. W. B. Osborn in the chair.—The Chairman announced that the Society was greatly indebted to Messrs. Morgan & Kidd who had generously presented a magnificent bromide enlargement of a portrait of the President (Sir J. B. Stone). The enlargement, which was made from a negative taken by Mr. Harold Baker, forms a conspicuous feature on the walls of the club-room. Mr. George A. Thomason then delivered a paper on *Stereoscopic Photography*. (See a future number.) A discussion followed, in which the Chairman, and Messrs. Griffiths, Iliff, A. J. Leeson, Owen, T. Taylor, E. Underwood, Watson, and G. Wilkes took part.

Brechin Photographic Association.—September 21, Annual Meeting, Mr. A. R. McLean Murray in the chair.—The usual reports of the Secretary, Treasurer, and Curator were submitted and appproved of. The Treasurer showed a balance in favour of the Society, and intimated that the debt incurred by the fitting up of the rooms had now been wiped off. The Curator showed that the lantern had been well taken advantage of during last winter, being borrowed by members on twenty-two different occasions. The following office-bearers were elected for the comiug year:—*President:* Mr. W. Shaw Adamson, jun., of Careston.—*Vice-Presidents:* Messrs. H. Braid and Bailie Lawrence.—*Committee:* Messrs. G. F. Robertson, B.Sc., J. Buchanan, A. Brown.—*Curator:* Mr. J. C. Middleton.—*Treasurer:* Mr. A. Innes.—*Secretary:* Mr. James D. Ross, 6, High-street, Brechin, N.B. The Association having been engaged during the past year in preparing slides to illustrate the manufacture of linen,

the slides ready were exhibited to the members. It was intimated that at the next meeting the Secretary would give a demonstration of *Enlarging on Eastman Bromide Paper.*

Liverpool Amateur Photographic Association.—On Thursday evening the formal opening of the beautiful new club-room was celebrated by an "At Home" given by the President, Mr. William Tomkinson, who gave a most humorous poetical effusion, specially written by Mr. Clarence E. Dyall. The Committee of the Artists' Club, whose rooms adjoin those of the Photographic Association, very kindly lent the use of their rooms for the occasion, thus enabling the President to invite the whole of the members (upwards of 300) and their lady friends. An excellent musical programme was contributed by Miss Anyon and Messrs. Cleaver, Yates, Bleu Rarn, Talbot Kelly, Anyon, Macready, and H. and W. Norman-Thomas. Mr. Yorke convulsed the audience with his humorous recitations. Mr. George E. Thompson gave his interesting new lecture on *The Roman Campagna*, illustrated by slides from negatives taken by him in the spring of this year. The lecture was listened to with great attention, frequent bursts of applause testifying to the appreciation of the crowded room. After an interval for refreshments, votes of thanks were accorded to all who had so kindly come forward to assist, and to the President or his entertainment. An impromptu dance, which was entered into with great spirit, brought a most enjoyable evening to a close.

Correspondence.

☞ *Correspondents should never write on both sides of the paper.*

"THE MALCONTENTS" AND THE PHOTOGRAPHIC EXHIBITION.

To the EDITOR.

SIR,—I have read the comments in the *Times* on the Photographic Society, which I feel convinced could not have been written by one of its staff. I am truly astonished that a paper of such standing should lend its columns to air the fancied grievances of a few disappointed men, deficient in gratitude for the many benefits received in past times from a Society they now condemn. The statements set forth are utterly false, and none know that better than the writer. The Society has never been more prosperous or firmly established than at present, and the Exhibition now open has been pronounced by competent judges and the public press to be the best ever held by the Society; and, although a few of the former exhibitors have abstained from contributing, their place has been amply filled by others, who surpass in some respects the absentees. I am not alone in this opinion.

The *Times* says: "It is rumoured that Captain Abney intends to resign at the end of his term." May I also add it is rumoured that the article is from the pen of a gentleman whose identity and connexion with the malcontents it is not difficult to recognise? With regard to this rumoured resignation, a rumour existing only in the mind of the writer, the President has always shown such great interest in the welfare, and worked so zealously for the Society, that he would scarcely resign at the bidding of a small band of discontents. His scientific duties falling heavily on him may perhaps influence his so doing, but he is much too reticent a man to inform all the world what his intentions may be.—I am, yours, &c., W. ENGLAND.

7, *St. James's-square, Notting-hill, W., September* 28, 1892.

[Some of the *Times'* comments and statements on matters concerning the Photographic Society of Great Britain and its Exhibition were so obviously of the *suggestio falsi* as well as of the *suppressio veri* kind, that we found it impossible to include them among our extracts of "opinions of the press" on the Photographic Exhibition.—ED.]

REVERSED NEGATIVES.

To the EDITOR.

SIR,—I myself was, I believe, the first professional using a negative from a negative for reversed images. The enclosed remarks I came across to-day, and send them for the benefit of any one requiring them. Finding I obtained a negative instead of a positive by contact, I set myself the task of finding out how it occurred. In making a few experiments to find at what stage of the exposure the reversal occurred, I exposed several plates behind a negative to the light of a paraffin lamp, three-quarter inch wick, with the following results:—No. 1, one minute exposure, very over-exposed positive; No. 2, three minutes exposure, gave a good negative; No. 3, two minutes exposure, developed as a positive, and just as I thought to discontinue the development it turned negative, and was very inferior to the one exposed three minutes. No. 4, four minutes exposure. This developed negative from the beginning, but the result not so good as No. 2. Plates used, Rouch's; developer, ferrous oxalate. I am now making them on Ilford plates, with an exposure of six seconds to bright sunlight, ferrous oxalate developer. I have found it a very simple matter, and can thoroughly recommend it. Mr. Howard Farmer has some I made some years ago, 1887, when a student at the Polytechnic, which were as good as the original, and sometimes they look better. E. FREWING.

26, *Eden-street, Kingston-on-Thames, September* 22, 1892.

FRENCH INVENTORS.

To the EDITOR.

SIR,—You are perfectly right in ridiculing, in your last number of THE BRITISH JOURNAL OF PHOTOGRAPHY, the idea of showing us the moon at one metre's distance, and that, too, by a Frenchman! If it were an Englishman, there would be some show of sense; but a Frenchman—pshaw! the idea!

What did your grandfather say when steamships and locomotives were mentioned to him? What did your father say about gas for lighting, and telegraphs? What did *you* say some thirty years ago about telephones and phonographs? And to-day you fall into the same trap, all ridiculing an idea, perhaps a little exaggerated—but don't say impossible. It is true it comes from France, and not England. Even Daguerre, if not an Englishman, was of English descent, as his changed name conclusively shows, it being originally Dagger—the English dagger.

Besides, you should not advance yourself so imprudently. The maker of the instrument may be one of those famous *photographic amateurs*, and there is no telling what such a man may produce.

Not more than a few months ago you were ridiculing Lippman—another English name, if any—and now some one improves on his idea in reproducing the spectrum.—I am, yours, &c., A. LEVY.

4, *Avenue Pinel, Asnières* (*Seine*), *September* 24, 1892.

[Nay, good friend, joking apart, we have never been slow in awarding credit to your countrymen for their invaluable inventions and discoveries in all that relates to photography; but (and we say it with bated breath) some of the inventions of *La Belle France*, not necessarily photographic ones, have not been such as to divest them entirely of the charge of having been impracticable, while, *per contra*, we have a hazy idea that certain emanations from English inventors and manufacturers have not quite proved failures, as an appeal to your own good memory and knowledge of what is being used in France will testify.—ED.]

HYPO-CARTRIDGES.

To the EDITOR.

SIR,—I see that a correspondent wishes to know where the hypo-cartridges are to be procured. I get mine from Messrs. Haacke & Albers, in Francfort-on-Main. They are sold in boxes containing ten, at 1s. 6d. per box. The ten cartridges are sufficient for sixty ounces, or two litres of fixing solution. They contain four parts of hypo and one part of acid bisulphite of soda—not metabisulphite as your correspondent supposes. They render the use of an alum bath after developing quite superfluous, and the solution remains bright and limpid until exhausted, which may be known by the very slow disappearance of bromide of silver from the negative. They are *most* convenient, and I am never without them.—I am, yours, &c. ETHEL C. MAY.

Darmstadt, September 26, 1892.

Exchange Column.

Wanted, background, burnisher, or changing bag, in exchange for *carte* portrait lens.—Address, J. G. BRADER, Hemingby, Horncastle.

Exchange 5×4 (No. 4) Regular Kodak for gentleman's gold lever watch and chain.—Address, A. VALENTINE, 30, Daubury-street, London, N.

I will exchange 12×10 camera with three double dark slides for a cabinet lens.—Address, H. L. MOSEL, Angel-row, Market-place, Nottingham.

Wanted, cabinet portrait lens of good make in exchange for whole-plate portrait lens by Lerebour.—Address, JAMES LEDGARD, Camm-lane, Mirfield, Yorks.

Will exchange Lancaster's Multum-in-parvo enlarging apparatus, 15×12 size, for some good rackwork slides.—Address, P. J. LEEMANN, Photographer, Mold.

Wanted, a half-plate rectilinear lens in exchange for Marioo's largest size registered washing apparatus.—Address, H. A. M., 16, Waterloo-place, Sunderland.

Will exchange 10×8 portrait lens for either 9×7 Euryscope or 10×8 rapid rectilinear Optimus; specimens submitted.—Address, ROBERT C. DAWS, Lock View, Bingley.

Answers to Correspondents.
